The Royal Horticultural Society's Daffodil Year Book.—I am hard at work on this book collecting material. On the 29th ult. the Narcissus committee approved the voting list for the lists of varieties most suitable for various purposes. These will be on the lines of those that are issued in the National Sweet Pea Society's Year Book, and should prove useful for reference. Our Year Book will also contain reports of the Royal Horticultural Society's London Daffodil Show, together with a full list of all the varieties that were staged there, and also at the Midland Show at Birmingham in the competitive classes. Among the other contents there will be several articles of general interest, lists of awards in 1913, descriptions of some of the best of the novelties, and numerous illustrations. I hope it will be issued early in August, and that the price of the same for those who are not members of the Royal Horticultural Society will not be prohibitive.

The Merodon.—Mr. Stocks' paper in THE GARDEN for April 27 will have been read with much interest. Without wishing to unduly frighten anyone, there seems to be very little doubt that the fly was present in considerable numbers

in many places last spring and early summer. I have an idea that the present inclement weather may prove more effectual than Mr. Stocks' racquet net; but it neither of these has touched the cause, then it will be well worth trying the water method, which Mr. W. Pompart of our Narcissus committee told me his sons, who carry on a large cut-flower trade, had found very efficacious last autumn. The mode of action is to steep all stocks which are suspicious in large tubs of water for three days, at the end of which time, when the bulbs are taken out and the water drained off, a deposit of merodons is found. The steeped bulbs did not suffer, he said, in the least, and flowers from them were as good as usual this spring.

JOSEPH JACOB.

SPRING FLOWERS AT WISLEY.

THE Royal Horticultural Society's gardens at Wisley contain much that is of interest at

the rocks, much in the same way as *Ranondias* are usually arranged, forming rosettes on the face of the rocks.

In the moraine we found a fine plant of *Asperula suberosa* flowering well, while *Cheiranthus Harpur-Crewe*, *Parochetus communis*, *Cytisus kewensis*, *Antirrhinum Asarina* and *Myosotis Rebsteini* were other plants in the rock garden proper that called for special mention. In a small circular bed near the old rock garden, *Gentiana acialis* was a blaze of brilliant blue, and near the pond, not far away, *Polyanthes* provided a broad belt of colour such as one is not often privileged to see.

In the woods we were much interested in a fine little colony of *Trillium grandiflorum roseum*, the largest-flowered variety of its class, some of the blossoms measuring 6 inches in diameter. The delicate blush rose colour of the blooms cannot fail to charm those with artistic tastes, and it is a fine plant for a damp, shady spot. Under

A BEAUTIFUL WATER-SIDE GROUPING OF POLYANTHUSES IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT WISLEY.

every season of the year, but it is during the spring months, perhaps more than at any other time, that the visitor will find numerous plants that call for comment. This is emphasised more than usual this spring, now that the immense rock garden is getting clothed with alpine vegetation of many kinds. When visiting the gardens on the closing day of April, we found a vast quantity of choice and well-grown plants. In the rock garden, that gem of flowers, though one that many find a difficulty in growing, *Lewisia Tweedyi*, had just opened its first flower. There was a small colony of plants, keeping company with *L. Cotyledon*, both being planted in an open position on a slight mound, and in grit and leaf-soil with a moisture-preserving top-dressing of granite chips. Not far away we found a fine little colony of *Saxifraga Grisebachii* just coming into flower. These were planted facing south-west in the cracks of

the *Camellia* bushes near by. *Shortia galacifolia* was growing like the proverbial weed, forming a large tuft more than a yard in diameter, and evidently perfectly happy in its shady home. Near by, the large stems of *Lilium giganteum* were pushing upwards, giving promise of a rare display of beauty and perfume in later days. On a large, sloping bank near the entrance we were much interested in *Narcissus Philippe Vilmorin*, a beautiful white variety, unusual on account of the great length of the trumpet. Apparently it is but little known in this country, but it is exceedingly beautiful, and has proved a great favourite with visitors to Wisley this spring.

In the glass-houses we found some of the finest plants of *Perpetual-flowering Carnations* we have ever seen, and in the adjoining house, and keeping company with the show *Pelargoniums*, were magnificent flowering plants of *Schizanthus*. Fellows

of the Society are fortunate in having such gardens as these, where many valuable lessons in the cultivation of choice plants can be learned, and where the whole staff is the very essence of courtesy.

BORDER CARNATIONS IN NEW ZEALAND.

USEFUL HINTS FOR HOME GROWERS.

DOUBTLESS we all at times wonder how our favourite flowers prosper in distant lands. A letter recently received from New Zealand's best-known and most successful Carnation-grower answers this question as regards his own hobby in a most interesting manner, so interesting, indeed, that it would be unfair not to give your readers the benefit of his experience and methods.

The gentleman in question is Mr. H. A. Fox of Wellington, and to those who do not know his name I would like to introduce him as a really great Carnation specialist, and a gentleman whose word can be taken as a true and unexaggerated story of his floriculture. He is a firm believer in the best that can be procured, whether it be labour, compost, or plants, and his collection of border Carnations is thoroughly up to date. Each season he imports the best novelties from England, and seems to prefer this process to layering his own plants, even for the older sorts, and the reason for this brings out one of the most interesting points of his letter. The layers are sent out in the autumn, as soon, indeed, as strongly rooted; but, naturally, a trying and unstable voyage of nearly two months, with its attendant state of semi-starvation, gives them a severe check. Now, here comes the point—these plants arrive and are planted just before the solstice of the Antipodean summer, and one might imagine they would make rapid progress and perhaps bloom in the autumn, *i.e.*, in February or March. But they do not; the check seems to be just sufficient to hold them back, so that they make a whole year's root and grass growth before flowering. The result is really wonderful; but before going into details let me give Mr. Fox's methods of culture from the beginning.

In readiness for the plants the ground is trenched 2 feet deep. Very old horse-manure is used to enrich the soil, with a sprinkling of superphosphate in the bottom spit. When the plants arrive, some time in December, they are put straight into their flowering quarters and allowed to grow without protection, except from wind and rain. As the New Zealand springs are notorious for furious wind-storms, some protection *must* be afforded, and Mr. Fox secures this by means of curtains of cheese cloth or unbleached calico carried along the two sides of the beds, the ends remaining open, and free ventilation ensured by keeping the curtains 6 inches off the ground. As soon as colour shows in the buds, all the beds are covered, some by

glass lights and some by oiled paper stretched over lattice-work. Regarding these two coverings it was found that the glass was the better in dull weather, the paper in hot, the latter, naturally, being cooler while still admitting plenty of light. As soon as these covers were on, light liquid stimulants were started, weak natural manure frequently being used.

By this time the plants, which have been developing for nearly a year, are mostly 18 inches in diameter, with from eight to twenty main flowering stems per plant! These flowering stems are from 3 feet to 3½ feet long and as thick as one's little finger. Disbudding is, of course, adopted, only the crown and the two lowest buds being allowed to develop.

And now for results, all of which Mr. Fox states are absolutely correct. On one plant of Eros twenty excellent blooms were open at one time,

of the whole show with a superb Mrs. J. L. Gibson. This flower was one of eleven off the same plant and exhibited at the same show. What thews and sinews these plants must be endowed with under such culture!

Disease seems to have a very small part in the life of these horticultural giants, soft blooms being the only trouble of consequence mentioned; and that seems to be something of a mystery to one who has had no opportunity to investigate on the spot. Probably this state is brought about by bees causing the flowers to collapse by hybridity. The illustration is of a bloom of the new border Carnation Bookham White, grown by Mr. Fox, which as a border white he considers is without equal, its dazzling whiteness and matchless form proclaiming it to be the white *par excellence*. As the flower was New Zealand grown, so were the photograph and block New Zealand produced, the former having been taken by that well-known New Zealand florist, Mr. Lord of Wellington, at the Nelson Show.

J. DOUGLAS.

Great Bookham, Surrey.

SOME GOOD BORDER THALICTRUMS.

THE majority of *Thalictrums* are most interesting on account of their elegant foliage, which is generally much subdivided and is suggestive of the popular *Adiantum* on an enlarged scale. *Thalictrum aquilegifolium purpureum* presents flowers that are of conspicuous beauty. They are borne in giant heads, forming billowy-like masses that surmount the leaves and form commanding objects in the border during June and July. In the variety under notice the flowers are coloured deep mauve, and these are usually succeeded by seed-pods that are distinctly coloured a similar shade. It is an easy subject to grow in ordinary garden soil that is well drained, and is propagated by seed sown in spring, the seedlings, when large enough, being transplanted to nursery beds in the open, thereby ensuring strong plants to flower the following year.

Two new *Thalictrums* from China are among the most desirable of recent novelties. These are *Delavayi* and *dipterocarpum*. They differ from the plant already described, in that the individual flowers are much larger and are arranged at wider intervals on the elegant spikes. *Delavayi* is the dwarfier plant, with pretty lilac-coloured flowers. *Dipterocarpum* attains a height of 5 feet when fully established, the flower-stems being extremely graceful, with the lightly-poised flowers of a bright rose purple, to which the citron yellow anthers form an admirable contrast. These Chinese species enjoy an open, sunny position in any light yet rich soil. They do not object to a partially-shaded position, provided moisture is not excessive in winter, as cold, wet soil starves and weakens them to such an extent that they suffer in comparison with those in more favourable positions.

Coombe Court Gardens.

THOMAS SMITH.

A SUPERB BLOOM OF BORDER CARNATION BOOKHAM WHITE, GROWN IN NEW ZEALAND.

and forty buds remained after the disbudding process mentioned above. Off two plants of Mrs. Robert Morton, Mr. Fox had twenty-four show blooms out on the same day, most of them 3½ inches in diameter. John Kidd carried flowers up to 3¾ inches, while Linkman went one better, a bloom staged at Nelson (South Island) being measured in front of competitors and exactly touching 4 inches! Renown is a special favourite with Mr. Fox, who says he had two flowers of this 4 inches across and "were real champions." But the giant of the lot was Bob Acres, which, shown at Lower Hutt, a Wellington suburb, measured as it stood 4½ inches, and a perfect flower at that. At the chief show in Wellington Mr. Fox carried all before him, winning the £5 5s. trophy for twelve blooms and the £2 2s. trophy for twelve with own foliage, also champion bloom

GARDENING FOR BEGINNERS.

HOW TO INCREASE HERBACEOUS PHLOXES FROM CUTTINGS.

THE usual way of increasing Phloxes is by division. Of course, this is by far the most expeditious, and one can depend on having good plants the following year; but when we come to compare the quality of the blooms with those of plants raised from cuttings, then we must leave the subject. The reason is obvious. In the case of division we have simply a portion of an old, partially worn-out plant, while from the cutting we have a young plant full of vigour. For filling beds the plants raised from cuttings are far more

1.—A PHLOX CUTTING WITH THE LOWER LEAVES REMOVED READY FOR PLANTING.

suitable in every way. The plants grow vigorously and uniformly, both as to height and size of flower-heads, and these are twice, or even three times, as large as those from divided plants.

The Phlox is a most useful and popular flower, becoming more and more so each year. This is due largely to the great improvement which has taken place in the colours and vigour of the plants. As above stated, there is no comparison between the heads of bloom produced by plants raised from cuttings a year old and those from old plants or pieces of old plants. There are two seasons which are suitable for rooting the cuttings—spring and autumn. Personally, I prefer spring, because we get the most vigorous cuttings full of life at this season, while in the autumn the vigour has naturally gone after the plants have been flowering, and we have to depend on secondary growth, too, for our cuttings. The weaker cuttings will readily root and grow into good plants, but there will be a lack of vigour as compared with the spring-rooted plants.

How to Take Cuttings.—The process of rooting the cuttings is a most simple one. I have found nothing better than a simple packing-case, with its bottom removed, and this set on good, sandy soil. The soil should be 10 inches deep and pressed firmly. Cover the surface with sand, and dibble the cuttings in rather thickly, as shown in Fig. 2

A sheet of glass should be placed over the case, and this should be thinly shaded by a little lime-wash to keep the strong sun from the cuttings. On no account should the cuttings be allowed to flag; this would retard the rooting process considerably. It is surprising how quickly these vigorous cuttings will root at this season of the year if properly attended to. The usual time is three weeks; this will be indicated by new growth at the points of the cuttings. As soon as this is observed, air should be admitted freely, and as soon as it is seen that the cuttings stand the free admission of air, the glass should be removed entirely. There should be no coddling. Grow the cuttings as hardy plants should be grown from beginning to end. There is nothing which fosters disease in hardy plants so much as coddling. Some recommend the propagating-case on warm manure. I do not like this. Place it on a warm border which is sheltered from winds. I think this is much better. As soon as the cuttings are well rooted, transplant to nursery beds of good soil. Give the plants plenty of room to develop during the summer months. Fig. 3 shows the kind of plant to be placed in the nursery bed. This is a sketch of an actual plant rooted last autumn, and which has developed several embryo buds at the base of the stem, just ready to burst into growth. This would make a fine subject for autumn planting in bed or border, and such a plant would give a good account of itself in the summer of 1914.

Phloxes are gross feeding plants, and resent drought as quickly as any herbaceous plant I know; therefore an abundance of water and an occasional dose of liquid manure will be of great benefit during the growing season.

A. T.

HOW TO GROW VEGETABLE MARROWS.

There are few more popular vegetables with beginners in gardening than the Vegetable Marrow, and in many country districts extraordinary methods of cultivation are adopted. Size seems to be the sole object, and with this end in view the plants are gorged with liquid manure until their flavour is sadly impaired. To get good, sweet, medium-sized Marrows extraordinary preparation of the soil is not necessary. Just before planting or sowing, a hole about eighteen inches in

3.—A ROOTED PLANT READY TO GO INTO A NURSERY BED.

diameter and the same in depth should be made for each plant, and with the bottom soil, which must be well broken up, but left at the bottom, some well-decayed manure ought to be mixed. This will tend to keep the soil cool and moist during the hot days of summer and autumn. It is usual to put out plants which have been raised under glass, and, if this is done, the end of May will be quite early enough for planting. But, contrary to what many amateurs suppose, seeds may be sown outdoors where the plants are to grow, and often give the best results. Where this course is adopted, the sooner the seeds are put in now the better. The danger with plants raised under glass is that too often they have not been sufficiently hardened off previous to putting them outdoors, when they receive a severe check, from which they rarely recover. Copious supplies of water during dry weather are essential for the well-being of the plants, and a sharp look-out must be kept for black fly.

2.—PREPARED CUTTINGS PLANTED IN SANDY SOIL IN A DISUSED PACKING-CASE AND COVERED WITH A SHEET OF GLASS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Erica carnea.—This spring-flowering Heath is most useful for edging beds of shrubs, and usually makes a good show from February onwards; but having now gone out of flower, it should be cut over, and if the plants have become straggly, they may be taken up and replanted; or if a compost of sand and leaf-soil or peat is mixed up and worked in among the plants, most of the branches or growths will root freely into it, and they may be divided and replanted in the autumn.

Ribes.—Plants of this family present the most graceful appearance when allowed to bloom on the full length of the previous season's growth, though I have seen them kept trimmed similar to a clipped Box or Yew. When the plants are as large as their position warrants, I prefer to cut them hard back after flowering, thus securing long, free growths for blooming next spring.

The Flower Garden.

Annuals.—Where annuals were sown very early, thinning should have been done before now; but in many districts the wet state of the soil prevented sowing till quite the middle of April. These, however, should now be ready for thinning. Unfortunately, in many instances annuals are not thinned sufficiently, thereby losing a great deal of their beauty and shortening the flowering period.

Wallflowers should now be sown on rather a light piece of ground, and if it has been dressed with a little wood-ashes and lime, so much the better. This I have found to induce a much finer rooting system, which is an advantage, as the plants have often to be shifted during the heat of the summer.

Plants Under Glass.

Sweet Peas under glass are now blooming profusely, and plenty of water and manure will be necessary to keep them up to the desired standard. Give a little shade during the day when necessary, and keep the temperature down as much as possible, thus retaining the colour and substance in the blooms.

Begonia Gloire de Sceaux.—Cuttings of this useful winter and spring foliage plant should now be put in, using the young shoots that spring from near the base of the plants. These are preferable to the old flowering points, as they grow so much stronger and make much larger leaves.

Begonia Gloire de Lorraine.—Cuttings put in early in April should now be ready for removal from the propagating-frame, selecting a shady position for them near the glass. A further batch of cuttings should now be put in, and the old stools thrown away.

Euphorbia pulcherrima and **jacquiniflora** that were placed in heat a few weeks ago should now have made sufficient growth for the cuttings to be taken off. As these are apt to bleed very much, the cuttings should be placed at once in a pot of very fine, dry sand, afterwards inserting the cuttings singly in 2½-inch pots and plunging in a propagating-frame with a fair amount of bottom-heat.

The Kitchen Garden.

Cauliflowers planted out of pots must be well looked after if the weather is dry, as they take some little time to get a good hold of the soil, and before they do this there is great danger of the balls of soil becoming dry. Plants in frames or pots that are turning in must be liberally supplied with manure-water.

French Beans.—After this date it is not necessary to sow in pots or frames; but to keep up a regular supply, small batches should be sown in the open ground at fairly frequent intervals, bearing in mind that they go on cropping over a longer period in the open ground than they do under glass. Early batches that may be coming through the soil should have pots placed over them at night, should there still be signs of frost.

Potatoes.—Early Potatoes on borders are growing apace, and after breaking up the soil well it is advisable to keep it drawn up to the plants almost daily, when, in the event of frost, it may save them somewhat.

Later Batches should be hoed through as soon as the rows are discernible, but not at a time when there is a likelihood of frost, as I have often seen much damage done where the soil has been moved immediately beforehand.

Fruits Under Glass.

Watering.—At this season regular attention must be paid to watering the borders of fruit-houses. Where these are fairly shallow and well drained, it is almost impossible to give too much water, and certainly once a week water may be given if the weather is hot. Where the borders are not well drained, rather more discretion will be necessary, and an examination of the borders should be made before applying water, or stagnation may result.

Feeding also is very essential, and though much may be done with animal manure, it is to the judicious application of artificial manures that one looks for the best results. Trees or Vines carrying heavy crops will take a fair amount of manure, both animal and artificial, during the growing season; but young, free-growing trees or freshly-planted Vines will, in most instances, get sufficient nourishment from the newly-made borders, and the application of much manure in the young stage often ruins the constitution of the recipients.

Hardy Fruits.

Disbudding.—Continue the disbudding and thinning of Peaches and Nectarines as they become fit, nailing or tying in the young growths as soon as they are long enough. Walls sometimes keep a lot of moisture from the borders, and where the trees do not appear to be doing as well as they might do, it may be found they are requiring water, even though there may have been sufficient rain to keep the trees in the open well supplied.

Trained Pears.—After these are nicely set I make a practice of giving a thorough wash down with the hose or garden engine, thus removing all the imperfectly-set fruits. If there is a heavy set of fruit, the trees should be gone over, removing a portion of the fruits, leaving those which in the small stage appear most prominent and likely to be in a good position for light and air, a second thinning being given at a later date.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Sweet Peas.—Young plants should be examined to see that all are taking to their supports. Some cultivators now denude the plants of their tendrils, so that the plants are entirely dependent upon the support afforded by the tying material. The utility of this mutilation I have as yet failed to see.

Staking Carnations.—This operation must now be taken in hand, or the flower-stems may get broken over. Wire coil stakes are now the most popular, and they certainly have the advantage of being easily manipulated; still, if the aim of the gardener is to hide his art as far as possible, then I opine that the coil wire stake is rather too intrusive, and I prefer Bamboo tips; but every man to his taste.

Planting Annuals.—Most of the annuals, both hardy and half-hardy, may now be planted out in prepared ground.

The Pleasure Grounds.

Mowing.—This work now demands unremitting attention. As far as possible, the mowings should be allowed to remain on the lawn, and if in any case they are unequally dispersed by the mower, a turn with a Birch broom will put things right. Of course, where games are being played it may be imperative to have the mowings removed. In such a case the utility of having a mower provided with a grass box is seen; such a machine, for example, as the Caledonia.

Rolling must also be attended to, especially where games are being played.

Clipping Edgings.—It seems common-place to refer to such an obvious duty as that of keeping edgings regularly clipped; still, it is sometimes

postponed unduly, to the detriment of the whole surroundings. Cannot someone invent edging-shears with really secure handles? Even those with the bolt are not all they profess to be.

Damaged Trees.—It sometimes happens that the stem of an ornamental tree receives damage from a scythe or other sharp object, and as a consequence bleeding ensues. This is especially the case with resinous trees, such as the double-flowering Cherries. Various remedies may be applied. A good plan is to first smear the wound with Archangel tar, then give a thick coating of grafting-clay, and over this place a layer of moss and finish with a bandage of binder twine.

Plants Under Glass.

Cannas.—These will now be growing apace, and should have copious supplies of water at the roots, with frequent syringings overhead. Being gross feeders, they will be benefited by occasional doses of liquid manure.

Top-Dressing Liliams.—Many Liliams, more especially auratum and the varieties of lancifolium, are much benefited by receiving a liberal top-dressing, for which ample allowance should be made at the time of potting. A mixture of equal parts of dry cow-manure and fibrous yellow loam in a rather lumpy condition suits the purpose admirably. The top-dressing should not be pressed too firmly, as the fleshy roots of the Liliams revel in a rather porous medium.

Callas.—Except a retarded batch, these will now be better in the open air, and it is a debatable question whether they are better left in their pots or planted out. Good results can be produced by either system. Personally, I prefer the latter, as by it the finest foliage—half the beauty of the plant—is generally produced.

Fruits Under Glass.

Figs.—Except where fruit is ripening, fairly moist conditions must be maintained, and on no account must the trees be allowed to suffer for lack of water at the root. If the root-run is sufficiently circumscribed, trees swelling their fruits will be benefited by frequent applications of liquid manure.

Peaches.—The bearing shoots should have their terminals shortened to about four inches, to give more room to the succession shoots. In houses where the fruit is stoned, the trees will stand a minimum temperature of 60°.

The Hardy Fruit Garden.

Training Wall Trees.—Attention will have to be given to the nailing in of the young shoots and of thinning and regulating the growth. Where a leading shoot is making too luxuriant growth, it should be trained slightly downwards to check the flow of sap; if, on the other hand, a shoot is weakly, it should for the time being be trained in an upward direction to encourage the flow of sap.

Thinning Stone Fruit.—Apricots and Peaches should have their fruits thinned to reasonable proportions. The object should be to have the fruits as equally distributed over the tree as possible, yet it is well to secure, as far as possible, the largest fruits. Badly-placed fruits should be discarded as far as circumstances will permit.

The Vegetable Garden.

Vegetable Marrows.—Where they can have the advantage of frames or hand-lights for a time, this useful crop may now be planted out under conditions indicated on page 245.

Celery.—Where not already done, the trenches must be prepared forthwith, and the width must be regulated by the number of rows it is intended to plant in a trench. Manure liberally, and either surface the finished trench with some specially-prepared soil or with some of the original surface-soil. Do not make the trenches too deep; 6 inches below the ground-level is sufficient when finished off. The young plants should now have the lights of the frame removed to harden off the plants.

Peas.—By topping the earliest sowing a gain of a week or so will be obtained. Except on retentive soils, sowings made now and subsequently had better be in trenches to conserve the moisture later on.

Successions of Kidney Beans, Turnips and saladings should be made. CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

SPRAYING TRIALS AT WISLEY.

An event of great importance to horticulturists recently took place at the Royal Horticultural Society's Gardens at Wisley, when spraying machinery from various sources was put to a severe test. The trials were thorough and exhaustive, and a deal of importance was attached to the spraying with unstrained lime wash, which placed fine nozzles to a very severe test. The judges were Professor E. S. Salmon, Professor H. M. Lefroy, Messrs. F. J. Chittenden, S. T. Wright, Henry Hooper, Cecil H. Hooper and C. R. Fielder. Every syringe and spraying machine was thoroughly overhauled and examined, and the cost taken into consideration in making awards.

Syringes.—In testing syringes the judges devoted special attention to the efficiency of the nozzles and their suitability for various washes. The efficiency of the nozzle was tested by directing the spray on to sheets of brown paper fixed to a temporary fence. An illustration of a syringe

THE TRAFALGAR SPRAYER IN OPERATION AT THE ROYAL HORTICULTURAL SOCIETY'S TRIALS AT WISLEY.

in operation appears on this page. Even with the best syringes a hollow spray was produced, and in this direction there is room for improvement. Two awards of merit were granted to syringes, viz., Four Oaks Undentable (angle bend excluded), sent by the Four Oaks Spraying Machine Company, Sutton Coldfield; and the Abol Syringe, from Messrs. E. A. White, Limited, Paddock Wood, Kent. The Abol Syringe gives a particularly good spray, and it is fitted with interchangeable caps, by means of which the user can vary the density of the spray from fine to medium or coarse, as desired. The Abol nozzle and the various parts, also the syringe complete with bend attachment, are illustrated on this page. The same nozzle applies to the Abol Knapsack Sprayer, which has the same fitting. The Four Oaks Undentable Syringe has a corrugated outer cover, so that the barrel within is undentable. Three grades of nozzles are supplied to this serviceable syringe, including a straight jet. An excellent spray was produced. Purser's Arnold Sprayer No. 2, from Messrs. G. and W. Purser, Limited, 92, Hatton Garden,

London, E.C., and Corry's Syringe were both commended by the judges. From the official report we gather that "The judges considered the provision of means of carrying accessory nozzles on the hand syringes would be a great improvement. None had such a provision."

Bucket Sprayers.—The only bucket sprayer to receive an award of merit was one entitled the Demon Continuous Spray Syringe, from the Boundary Chemical Company, Cranmer Street, Liverpool. (See illustration below). This pump, which provides an excellent spray, is made to fit any bucket. We understand that this firm is introducing a simple clip to keep the tube in the bucket, also a container to hold the spraying fluid, which can be carried on a shoulder strap. The Trafalgar Bucket Sprayer sent by Messrs. G. and W. Purser,

Limited, made a good impression, and on this page is seen an illustration of this sprayer in operation at the trial. In using some spraying materials the judges report that the provision of a strainer on the intake nozzle would be an advantage.

Continuous Pumping Knapsacks.—As the name implies, the knapsacks shown in this class have to be pumped while on the back. In the course of time this method, at present the most serviceable, may be superseded by knapsacks that maintain a continuous spray by means of compressed air. A good number of continuous pumping knapsacks were on trial, and awards of merit were made to the Abol, from Messrs. E. A. White, Limited; and Vermorel's Eclair No. 1 and Etame, both sent by Messrs. Cooper, Pegler and Co. The Four Oaks Centre Knapsack Pump was highly commended, and the continuous pumping knapsack from Messrs. Benton and Stone, Birmingham (Enot's), was commended.

Large Pneumatic Sprayers.—When more efficient, this type of machine will prove a decided advantage on the continuous pumping sprayer. The principle is that of pumping into the machine sufficient air pressure to expel all the liquid without further pumping. Messrs. Harjen and Co., 35, Noble Street, E.C., were highly commended for their battery filler and holders, which are of sound construction, and created a good impression among the commercial fruit-growers present.

Large Continuous Pumping Sprayers.—A very serviceable wheeled machine with powerful pumps, and known as the Four Oaks Large Continuous Pumping Battle Sprayer, was highly commended. This machine is furnished with two 15-foot lengths of armoured hose, and for spraying on a large scale it is decidedly useful. Messrs. Benton and Stone's Utility Sprayer, a wheeled machine with a powerful pump, was commended by the judges. It is particularly useful for spraying large standard fruit trees.

Hand Diffusers.—Quite a number of pneumatic hand sprayers specially constructed for greenhouse or conservatory work, and particularly useful to exhibitors who wish to freshen their exhibits at flower shows, were on trial. Most of them hold about four pints of water, and are easily manipulated. The Alpha Hand Diffuser, shown by the Alpha Extinguisher Company, was highly commended, and the Holder Hand Diffuser, by Messrs. Hartjen and Co., was commended. Both of these handy sprayers are fitted with an automatic stop cock, and so easily manipulated that any child might use them. The

Vermorel Hand Diffuser, from Messrs. Cooper, Pegler and Co., and the Hand Diffuser No. 1807, by Messrs. Benton and Stone, were both commended. The Four Oaks Nozzles worked in a

THE ABOL SYRINGE, WITH NOZZLE AND ADJUSTABLE SCREW PLUG.

most satisfactory manner and were highly commended by the judges. These trials are of immense value to horticulturists of all classes, as the awards were made by competent judges after thorough examination.

A SNAPSHOT PHOTOGRAPH TAKEN AT THE SPRAYING TRIALS.

POND WEEDS AND COPPER SULPHATE.

FOR several years past a considerable amount of trouble has been caused by the presence of a slimy-looking scum upon the surface of ponds, lakes, tanks and reservoirs in various parts of the country, and requests are constantly being made for information regarding a method of treatment which is likely to eradicate it without injuring Water Lilies and other aquatic plants and fish. The scum is caused by various kinds of Algæ, low orders of plant-life allied to the Sea-weeds, including species of such genera as *Anabaena*, *Spirogyra* and *Ulothrix*. It is not only in the British Isles that these or allied kinds of Algæ cause trouble, for they are prevalent on the Continent, in America, the Malay States and elsewhere. In some countries much trouble has been caused by their presence in reservoirs of water intended for domestic purposes, for, in addition to the loathsome appearance of affected water, it has frequently an abominable stench, and numerous experiments have been conducted at considerable expense with a view to obtaining a cheap method of cleansing the water without making it detrimental to animal or human life. Some of the Algæ form a considerable amount of growth below the water, and one common kind is popularly called Flannel-weed on account of its matted, thread-like growths. In the first place, people tried to rake all this growth out of the water, but that only created a temporary relief, and after a few weeks the water was as bad as ever. Neither did cleaning out lakes and pools prevent the recurrence of scum; therefore attention was directed to finding a poisonous chemical which could be applied in small enough quantities to kill the Algæ without injuring other plants, fish, animals, or human beings. A good deal of experimental work was conducted in America and other countries, the Americans, perhaps, being to the fore. As a result of these experiments it was found that the most satisfactory chemical to use was copper sulphate, and that salt has now been taken into general use for the purpose. Highly poisonous in its action, one part to 1,000,000 parts of water is sufficient to kill the Algæ, but one part in 750,000 parts of water causes no injury to Water Lilies nor to fish. In fact, the Americans report that gold-fish and minnows live indefinitely in a concentration of one part to 200,000, whereas some of the coarser kinds of fish will stand a one in 50,000 concentration, but certain delicate kinds are killed in a one to 500,000.

Regarding its action upon animals and human beings, it is argued that in a one in 1,000,000 solution, 50 quarts of water a day would have to be drunk before an amount of copper would be absorbed to cause any unpleasant action, and that after a few hours have elapsed from the time that the copper sulphate has been used, there would be very little in suspension in the water, as a large percentage combines with the Algæ or is otherwise precipitated.

From this there is really little to fear from the use of such a poisonous substance, providing it is used with care. In the first place, a careful calculation must be made of the holding capacity of the pond or lake to be treated. Then the weight of the water may be taken at about sixty-two and one-third pounds to the cubic foot, and the copper sulphate used in proportion. It may be applied

to the water in two ways—either dissolved in a little water and sprayed over the surface of the area to be treated, or tied in a canvas bag and drawn through the water until dissolved. When spraying the surface, it is as well to keep the mixture away from the leaves of Water Lilies, or it will probably burn them; once diluted with the water, however, it does not cause harm. On no account must it be used stronger than one part in 750,000, and it is better to adopt the one in 1,000,000 concentration.

In a Bulletin on the subject published by the American Department of Agriculture, it is said that Watercress beds are regularly treated in some parts of America without injury to the Watercress. An instance is also given of a Kentucky reservoir containing 25,000,000 gallons of water, from which in July, 1903, the smell became unbearable owing to the presence of various kinds of Algæ. This was treated with copper sulphate at the rate of one part in 4,000,000 parts of water. The Algæ was killed in two days, and the smell gradually disappeared. In addition to being used for killing Algæ, it is said that a concentration of one part in 100,000 kills typhoid and cholera germs in from three to four hours, and mosquito larvae die in a concentration varying from one in 100,000 to one in 200,000. As a rule, about two applications a year may be expected to keep the water clean.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Spinach.—Too many amateurs and cottagers who pride themselves on the vegetables produced in their gardens either neglect Spinach or grow it in such a manner that it is impossible for its full nutrient and medicinal properties to be developed. It ought to be borne in mind that it is one of the most valuable vegetables of the garden and, as such, entitled to proper attention. To ensure success with it in the summer, an open situation where the soil is deep and fertile must be selected, as unless the conditions are favourable the plants will "bolt" in a most disconcerting and disappointing manner. Thin seeding must be the rule, to obviate the necessity of much thinning and to encourage a thick-leaved, splendid plant from the start. The thinning should be followed up until the plants stand not less than 8 inches asunder in lines about one foot apart. Spinach is an excellent crop to grow between other kinds, but it must have plenty of fresh air and unobstructed light to build up its properties.

Scarlet Runners.—Between the present date and the end of the month is a particularly favourable time to make the principal sowing of this indispensable autumn vegetable, and the finest results can be achieved only when the site chosen is deep and the soil contains an abundant supply of readily available food. Natural manure is to be preferred to chemicals for this crop; but still heavier returns will be secured when the first named is used as a base and the food is increased by the aid of the concentrated fertilisers. It is essential that the drills shall be flat-bottomed, firm and level, and in no instance ought the seeds to be set closer than 6 inches, while the plants of Sutton's Best of All demand 12 inches to 15 inches in which to display their wonderful powers of growth and productiveness. Ample space pays with these as with other crops.

Salsify and Scorzonera.—These are useful change vegetables of which one or two good rows may well find a place in gardens, but much space should not be accorded, as it can be more profitably used for other kinds. Those who can spare a little room should sow the seeds immediately, as it is well on the late side. The drills ought to be about one inch deep, and the seeds should be dropped in clusters of three or four at intervals of 8 inches. Later on, thinning will have to be done to single the plants, and hoeing will keep things going.

Potatoes.—Amateur and cottage gardeners who like to postpone their tasks until the latest possible moment must now realise that unless they plant any Potatoes still remaining out of the ground at once, the plants will not have time to make perfect growth, and, in the absence of that, one cannot expect to produce a heavy crop of excellent tubers. Late varieties only will be available, and the lines should not be less than 33 inches asunder, and 36 inches is to be preferred in most soils, while 15 inches ought to separate the sets in the rows. The deepest digging, with generous but judicious manuring, is imperative if the finest results are to be secured. Plants of early varieties will be coming through the surface, and, directly they are seen, earthing must commence, or a sudden frost may come along and cut them down. In addition to earthing it is wise to have at hand a supply of protective material to hover on the bed if it is needed. Immediately prior to this first earthing is a suitable time to apply a dressing of an approved concentrated food to the plants.

Hoeing.—It is imperative that the hoe shall be kept running between the rows of all vegetables from the time that the lines of plants can be clearly seen showing through the surface. A constant state of looseness, to the point of dustiness, conserves the moisture in the soil and thus encourages incessant progress in the plants; while at the same time weeds are prevented from growing to the stage of flowering and shedding their seeds. Beyond these two things, each of which is of great importance, hoeing admits rain freely to the soil, and it is, of course, followed by the sweetening and invigorating fresh air. Thus in the one operation the cultivator does immense good in the encouragement of satisfactory growth. H. J.

THE EDITOR'S TABLE.

A White Pelargonium Sport.—Mr. F. W. Digwood, The Gardens, Harewood Park, Ross-on-Wye, writes: "I am sending some blooms of a white Pelargonium for your opinion. It is a sport from the pink one I enclose, Withyham. I have grown it now for five years, and it seems to stand all right." The flowers sent are remarkably fine, being over two inches across, pure white, with crimson stigmata and borne in large trusses. The petals are delicately fringed, and we regard this variety as an improvement on Purty.

Rose Niphetos from Bishop's Waltham.—Mr. E. Molyneux, Swanmore House Farm, Bishop's Waltham, Hants, sends some superb blooms of this old but fragrant and good white climbing Rose. The flowers that Mr. Molyneux sends prove, as he states in his letter, that Niphetos is still far from being played out, notwithstanding the many new varieties that are constantly being raised.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artists' or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

To Our Readers.—In this Special Double Number, which is twice the ordinary size, will be found an illustrated review of the Royal Horticultural Society's Spring Show, which was this year held in the Chelsea Hospital Grounds instead of the Inner Temple Gardens. For some years past the Temple Show has been so overcrowded that it was impossible for visitors to see the exhibits with any degree of comfort, and the Council very wisely decided to transfer the show to Chelsea, where the great International Exhibition of last year was held, and where there is ample space. Readers who have friends in this country or abroad who are interested in gardening should post them a copy of this issue.

Disbudding Roses.—During the next few weeks the disbudding of Roses, where such a course is adopted, will need attention. Where large, bold flowers are desired, there is no doubt that the removal of the weakest and badly-placed buds, leaving only the best one of each truss, has much to commend it. There are many, however, who prefer to allow their Roses to develop naturally, caring not that the flowers are small. The advisability or otherwise of disbudding is therefore purely a question of individual taste.

The Bardfield Oxlip.—This is the most beautiful of our native Primulas, and one that is by no means widely distributed. In common with the Cowslip, it has been flowering very freely this year, and recently, when in the Bardfield district, we noticed a very beautiful colony in a rather thickly-wooded plantation. Curiously enough, the natives of Essex call the Cowslip Peggle or Paigle, and the Oxlip is known to them as the Cowslip. The true Bardfield Oxlip is a plant well worth a place in the best gardens, and will thrive well in moist, loamy soil. It is generally regarded as a natural cross between the Primrose and Cowslip, but of this there is some doubt. Certainly in appearance it is midway between the two.

Honesty in the Wild Garden.—A very pretty effect has been noticed over a period of several weeks at Kew by an informal group of the common Honesty (*Lunaria annua*, or *L. biennis* as it is often called). Seeds were, apparently, sown broadcast among hardy Ferns growing in a thin shrubbery, and the plants, now a couple of feet high and masses of flowers, have not the slightest appearance of formality. Contrasted with the various shades of green seen in the young fronds of the Ferns and the leaves of the shrubs, the reddish flowers are seen to considerable advantage, and one cannot but admit that the plant is much prettier and better fitted for this method of culture than for planting in formal-shaped beds. As the seeds can be sown in the places where the plants are to flower, a good deal of trouble in transplanting is saved.

Azaleas at Kew.—Anyone who is anxious to see the Azaleas in flower at Kew would do well to pay their visit before the end of May, for the plants will be at their best about the last week of the month. Of the many outdoor displays at Kew, the show of Azaleas is one of the best, and large numbers of visitors make annual excursions to see them. Situated between the Palm House and the Rhododendron Dell, the Azalea garden is to be found in an opening amid large specimen Beeches and Oaks, the plants being arranged in a large number of beds on a smoothly-kept lawn. Here almost every shade of red, yellow and pink is to be found, and it would be difficult to imagine a finer picture than the masses of showy yet delicate colours of the flowers amid the setting of bright green leaves of the trees around.

Cunningham's White Rhododendron.—This is a fairly well-known evergreen Rhododendron, but its true value is known to few, or it would be cultivated much more extensively. Rhododendron Cunningham's White is a very hardy sort, escaping a severe winter when even the common *R. ponticum* has suffered. It also thrives in soil when lime is present; in fact, its general value, both in hardiness, growth and habit, is so good that the plant finds favour among propagators as a stock for the choice sorts, particularly on the Continent. For covert planting and shrubbery culture Cunningham's White equals, or even surpasses, *R. ponticum*. It flowers earlier than *R. ponticum*, being fully open usually about the middle of May. The flowers are white, with a faint flush of lilac or mauve, which as they reach maturity is less pronounced. Layering is the most satisfactory method of propagating this Rhododendron.

"Fire" in Tulips in 1913.—Owing to the inclement season, the flowers and foliage of Tulips have in many gardens been much affected with a fungus, known botanically as *Botrytis galanthina*. It shows itself as ugly, withered-looking spots, which, in damp weather especially, are often covered with "mould," and which rapidly extend in size and infect adjacent parts. If the attack is not too bad, constant picking or cutting off all the bad parts is advised. If the attack is so bad that nothing practically would be left if all the diseased places were removed, it will still be best to resort to the knife. The bulbs may then be left where they are to ripen off, or they may be lifted with their roots and put into boxes filled with light soil, where the same process may take place. Tulips should not be planted in the same soil the following year. Undoubtedly protection from cold and wind helps to keep the plants healthy. A constant watch should be kept at all times for the appearance of the spots, which should at once be removed and burned. Bulbs which have had their leaves destroyed by "fire" will be weakened in proportion to the extent of the damage done, and must not be expected to produce full-sized blooms the following year.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Crippled Pear Tree.—I was much interested to see the illustration on page 238 of last week's issue of a Pear tree which, though blown over, still continues to flower and bear fruit. Some years ago I had under my charge a half-standard Blenheim Orange Apple tree which, during a gale, was blown over in the same way. As the tree

A.—SUNDIAL FIXED FOR ENGLAND.

was about thirty years old and in its prime, and as it was not an inconvenience, it was decided to leave it. For some years afterwards, and as long as it was under my observation, this tree continued to bear splendid crops of first-quality fruit. Indeed, the check to the roots was undoubtedly beneficial, as the tree, in its crippled state, cropped more freely than before the accident. Many of the large roots were quite bare, but, of course, sufficient remained in the soil to nourish the tree.—A. B. Essex.

Cutting the Foliage of Bulbs.—Your useful reminder on page 225, May 10 issue, of the value of removing seed-vessels from bulbs is accompanied by another valuable one advising that the leaves should not be cut. The cutting of the leaves of bulbs is a much more common practice than is generally believed by those who grow them in a rational manner, and who allow the foliage to ripen before removing it, thus giving the bulb all the chances possible. One regrets, also, to see that so many leaves have been cut from Narcissi in order to supply the demand for their own foliage to accompany the flowers. It is impossible not to sympathise with the taste which counsels the use of their own foliage with such flowers, as they generally look better when so displayed than when set up with other leaves. One is led to pen this note from seeing so many Daffodils cut remorselessly down for foliage to use with the flowers. It is little wonder that so many complain of Narcissi refusing to flower and even dying out. A little consideration in the way of selecting foliage from several instead of from one or two plants only will palliate matters, but it cannot be too frequently impressed upon all that bulbous plants suffer greatly when their foliage is cut off prematurely.—S. A.

How to Grow Gentiana verna.—The Vernal Gentian is such a lovely flower that its requirements deserve full consideration at our hands. To succeed with it is to be the possessor of one of the choicest gems of the alpine flora. Unfortunately, just as with the Gentianella, G. acaulis, it is impossible to assert that it will succeed in any particular garden under certain treatment. In many gardens it has to receive special treatment, while in others it appears to grow with the minimum of difficulty. In my own garden I have now been successful with it in a low, rather moist part, exposed to the sun, however, but surfaced with stone chips, and these are kept renewed and brought up to the neck of the plants as there is occasion. I have seen it growing admirably on the top of a low retaining wall, with plenty of stones about it. In some places, however, I find it thrives well without any special care, save that afforded other alpinces.—S. ARNOTT, Dumfries, N.B.

How to Set a Horizontal Sundial.—If the sundial is for use as garden ornament, the following is usually considered a sufficiently accurate method of setting. Select a bright sunny day (as near as possible to the summer solstice is generally preferred), and, first making sure that the dial-plate is perfectly level, so arrange the dial that at twelve o'clock the shadow of the gnomon (or style) points to the XII. on the dial-plate. If, however, greater accuracy is desired, the first thing to be considered is whether the dial itself is made and marked correctly for the district in which it is to be used. A sundial made for the South of England would be useless in the North, owing to the fact that the style (or gnomon) must point to the Pole star, the altitude of which varies with the latitude. The angle formed by the style with a plate made for London would be 51½°. In Newcastle the angle would be more obtuse, being 90° at the North Pole. South of the Equator the angle becomes more acute the nearer the Equator is approached. Assuming that the dial-plate is correct for the district, a line drawn from the centre of the style, through the XII mark, should point to the Polar or Geographical North, which in England may be taken as 18° 58" East of the Magnetic North. Even with the utmost care having been taken in the manufacture and fixing of a horizontal sundial it can only be considered as supplying an approximate measurement of time. The accompanying diagrams illustrate the dial fixed for England in relation to the cardinal points as given by a mariner's compass (A) and the elevation of the style above the dial-plate for London (B).—GEO. DILLISTONE.

Primula cockburniana: How Far is It Perennial?—This question is asked by Mr. Arnott in your issue of May 10, page 229. Under certain conditions it is perennial, but sown annually and treated as a biennial better results are obtained. I have a bed here in which several plants flowered last year, and they are coming into flower again, clearly pointing to their perennial character. The position is in full sun. They are growing in very gritty soil, with a great proportion of broken chips mixed with loam, sand and leaf-soil. A foot of this soil on the top of another foot of coarser drainage will be found suitable to keep the plants in health for several years.—JOHN MACWATT, Morelands, Duns.

—Mr. Arnott's experiments with this charming plant are interesting, and I hope he may yet succeed in establishing its reputation as a perennial. So far, our experience here is but a confirmation of his. We have grown it both as a pondside plant with its feet in water, and in a high and

fairly dry position. It flourishes either way, but proves nothing but a biennial with us. There is no doubt that this and many other of the newer Primulas are but little understood at present. Some enthusiasts will, I hope, take them in hand and learn and teach all about them, so that we may handle them with the certitude and assurance with which we now handle Auriculas and Primroses. When they are better understood, the new-comers of the Primula family have a great reception awaiting them.—ROBERT PEEL SHELDON, Hawkhurst, Kent.

—I am afraid the most ardent admirers of this beautiful Primrose will have difficulty in substantiating its claim to be a perennial. True, there are instances where it has stood through three winters, as has been the case with those under the care of my old friend Mr. William Hutchinson at Terregles, as cited by Mr. Arnott on page 229 of THE GARDEN for May 10; but one or two isolated instances are not sufficient to warrant its being classed as perennial. I have grown this lovely little gem for several years, and have also been fortunate in keeping it through two winters in certain positions; but the great majority of the plants were nothing more or less than biennial. The plants, which survived two winters, were planted fairly high up in a pocket, facing east, in a thoroughly well-drained part of the rock garden. Others grown under similar conditions, but with a northern exposure, failed to live through the winter. The soil in which they were planted was a fairly light compost of yellow loam and leaf-mould, with some rough river sand added. The freedom with which P. cockburniana seeds and reproduces itself by this means amply justifies its being treated as a biennial; and really, after all, is it worth while trying to make it otherwise?

B.—ELEVATION OF STYLE ABOVE THE DIAL-PLATE FOR LONDON.

Beautiful little groups of year old plants are exceedingly effective, the richness of the colouring being very conspicuous, and I do not think that its biennial character will be in the least a drawback to its popularity. I shall, however, be interested to learn the results of Mr. Arnott's experiments with this very charming Primula.—WILLIAM LITTLE, Ochilview, Bridge of Earn, N.B.

Saxifraga Rhœi.—This Mossy Saxifrage is one of the freest flowering we have, and several fine clumps are now quite a mass of bloom. For several years they have been established on the rockwork of a bridge, with a very shallow root-run, subjected to extremes of heat and drought, cold and rains, and under trying conditions which many other plants resent.—E. BECKETT, *Aldenham House Gardens, Elstree.*

Silene acaulis for the Rock Garden.—Mr. Farrer, in "The Rock Garden," page 48, says: "Do not trouble about *S. acaulis*. It may grow well in soil or moraine, but it rarely, if ever, flowers as it should." I trust enthusiasts will not be put off by this, for I have just seen a patch in an alpine garden here so studded with buds that when it flowers it will be a sheer mass of pink which could not be beaten even in the Alps, except for size of the mass. It is growing in a light, limy loam in full sun with no special preparation. So let us still experiment with this exquisite native until success rewards our efforts.—E. B. ANDERSON, *Dublin.*

The Fifty Best Alpines.—I have been sorely tempted to send my list of the fifty best alpines, but I think the subject has been dealt with sufficiently. I only wish to remark that in none of the lists sent, nor for that matter in any catalogue I have (and their number is legion), do I find a plant mentioned which is very distinct and well suited for rock gardening. It rejoices in the name of *Tetraganobolus siliquosus* [*Lotus siliquosus*.—Ed.], at least so it was named to me by a resident of the neighbourhood where I found it, viz. Walchensee in Bavaria. At one time it threatened to be too great a robber of space in my small rock garden, and even now no stones can keep it in bounds. It comes out the other side and seeds freely. It has a pretty lemon-coloured Pea blossom. I am no botanist, and cannot describe it otherwise than as a *sleeping Pea*.—ELLEN E. SILVENSON.

A Living from the Land.—In the central column of page 230, *THE GARDEN*, issue May 10, there appears a splendid answer to a correspondent seeking for advice on the above subject. Other readers of *THE GARDEN* who may be contemplating working land in order to make a living from it should also read this reply. Sound advice is given, and such is always beneficial to enquirers. Facts must be faced and every detail connected with the matter duly studied. If would-be florists and market-gardeners would do all this, there would be fewer unfortunate ventures in this direction. A good home and a regular income should not be given up without much careful thought. It has been my duty to answer many enquiries such as the one referred to, and while giving due encouragement, I have never hesitated to point out all the drawbacks I am acquainted with, thus, because I know of many failures as well as successes.—B.

Toads in the Garden.—As stated recently in your journal, the value of toads as destroyers of insects in the garden is great, and they should be encouraged in every way. Many people dislike toads, and call them beastly and so forth. A closer acquaintance will, however, dispel this, for the eye of the toad is very beautiful, while its manner of disposing of insects and worms is most interesting. It will watch its prey for some time, and at the least sign of movement the long, glutinous tongue of the toad is protruded with a snap and the insect disappears. If it happens to be a vigorous beetle, its struggles against the sides of the toad may be seen for some little time. Toads may be encouraged in the garden by forming them a cool and shady retreat with a few bricks. One

lived in this way in my garden for a couple of years, until it unaccountably disappeared. It was so much at home that it would come out of its retreat to be fed when I whistled for it, returning to its quarters when satisfied. It would readily eat an insect from off my hand. A fact that interested everyone was that it would eat wasps and bees as readily as anything else. The toad being a cold-blooded animal, their stings had no effect upon it. To illustrate this I used to catch some wasps and imprison them under a bell-glass, and then slip the toad in with them. One by one as they came within reach of his tongue they were gobbled up. After the disappearance of my specimen, changes took place, which has prevented me from acquiring a successor.—H. P.

The Narcissus Fly.—I have been much interested to read the article by G. St. OX in your issue of the 26th ult., page 203, on merodons. I would like to add a little from experience also. The fly is to be recognised partly by its queer hum or sing of its wings and by its yellow or red lower part of its body, and it is easily confused with another fly, a sort of darting, hovering one that has a pointed

MR. S. T. WRIGHT.

tail. This is not a merodon fly. A fact of interest is that a fly will nearly always lay its eggs in the same bed and close to where it itself was hatched, and I think we can from this presume it will hang about that part of the garden border or bed. I have as far back as seven or eight years ago discovered that eggs late hatched do not mature into full-grown grubs in time to leave the bulb early in February or the end of January, and so remain on or eat their way into a neighbouring bulb. And, further, bulbs that are imported from abroad are far more infested with grubs than those grown in our country. Q.E.D., buy home-grown bulbs. Last year we had great fun with a net as described in the article, and digging up all our bulbs in the autumn, with carefully scrutinising those replanted, has resulted this year in no merodons being caught, though we have looked for them for days. We think we have seen one once.—W. F. M. COPELAND.

FORTHCOMING EVENTS.

May 27.—Rhododendron Show at the Royal Horticultural Society's Hall (four days). Bath and West and Southern Counties Society's Show at Truro (five days).

WORKERS AMONG THE FLOWERS.

MR. S. T. WRIGHT.

IT is with pleasure that we publish in this special issue a portrait of Mr. S. T. Wright, the genial superintendent of the Royal Horticultural Society's Gardens at Wisley. It is given to few men who are engaged in horticulture to come so prominently before the public as has Mr. Wright during the last seventeen years, the period that he has held the office he now occupies.

Practically the whole of his working life has been devoted to gardening, his horticultural career commencing at Snelston Hall, Derbyshire, under Mr. McPherson, who was regarded as one of the finest fruit-growers of the day. From Snelston Hall Mr. Wright went to Alton Towers under Mr. Rabone, and from there to Wood Seat in Staffordshire, the gardens of which were tamed in those days for Grapes. After two years there as fruit foreman, the subject of our portrait went as head-gardener to C. B. Kingdon, Esq., Ednaston Lodge, Derbyshire, a position that he occupied for seven years, until the estate was sold. Ross, near Hereford, was his next venue, head-gardener to C. Lee-Campbell, Esq., Glenston Court, being his position in the West Country. Here, in addition to the gardens proper, Mr. Wright had charge of extensive fruit plantations, and we find him spending ten years in this position, relinquishing it only when the lease of the estate expired. It was fortunate for horticulture generally that this expiration caused him to retire from Glenston Court, because at that time—in 1895, to be precise—the Royal Horticultural Society were casting about for a superintendent, and their choice fell on Mr. Wright, who commenced his duties on January 1, 1896.

How numerous and varied these duties are, few people really know. One would naturally assume that the supervision of the gardens at Wisley, with their many ramifications, would be sufficient in itself to keep him fully occupied. Yet until about two years ago, when Mr. Fielder was appointed to that position, he acted as official adviser of the society, and in that capacity visited and advised on Fellows' gardens in all parts of the United Kingdom, with the result that there are few localities with which he is not familiar. Then we find him at every one of the fortnightly shows held by the society at Vincent Square, superintending the erection of staging, spacing of exhibits, and acting as a sort of walking encyclopædia to any of the Fellows who may require his assistance. During the first season he is usually kept busy naming fruits, and it is doubtful if anyone knows hardy fruits better. Even obscure varieties of Apples and Pears that the average gardener has seldom or never heard of are an open book to him. It is at the great exhibitions, such as the Temple and Holland House, that Mr. Wright's genius as an organiser is put to the supreme test. Probably no one but he knows the difficulties that have been encountered at the Temple Gardens during the last few years in packing numerous and ever-expanding exhibits into a limited space, and it must have been a great relief to him this year to have the larger space in the Chelsea Hospital Grounds for arranging the great spring show. Imperturbable and courteous always, Mr. Wright is regarded by all those privileged to know him as the right man in the right place. That he may long be spared to fill it is our earnest wish.

THE FLOWER GARDEN.

SEASONABLE NOTES ON DAHLIAS.

THERE is perhaps no other florists' flower which has experienced such ebbs and flows of popularity as the Dahlia; but it is now, and has been for several years, on the rising tide, and it is likely to continue to advance in general esteem as long as we find the raisers of new varieties bringing forward the splendid qualities that have characterised the introductions of recent years. The improvement has been marked in every desirable direction, and if some genius would impart delightful perfume to the best quality of the day, we should have an ideal flower for our gardens.

The Dahlia is not a plant for one man, for one class of men, for one garden, or for one district, since it will grow anywhere, provided that the owner desires, or, better still, determines, to grow it. I have seen blooms in a backyard only a few feet square that would have graced any show-board in the country, and the cultivator was a shoemaker by trade.

There is one respect in which growers are prone to be at fault. They have a collection of varieties that has been steadily built up and contains, in their opinion, the very best. So far good; but they are too apt to rest content with those they have, and it is a difficult matter to persuade them to make changes. Herein they are correct to a point. To retain old favourites is sound from every point of view, but to fail to try one or two fresh ones every season is a short-sighted policy that can only result in the collection gradually, or rapidly, falling behind. It is quite immaterial how many varieties are grown; some additions must be made each year, and now is the time to do it. In **THE GARDEN** the leading specialists in Dahlias—as in other flowers, too, for that matter—advertise their wares, and they have at this moment excellent stocks of the leading novelties, and from them a choice ought to be made. No matter how superb a variety may be, trial will assuredly bring forth one that is superior, when the old stager will have to take a back place. On the other hand, the new-comer may not please, in which event it is safe to assert that the grower will not make a special effort to perpetuate it. The rule must be to make experiments with a view to keeping in the front.

Preparing the Soil.—This is an important task, and it ought to be put in hand immediately, that is to say, where it has not yet been accomplished. The plants are gross feeders, but this by no means implies that rotten manure should come in contact with the roots; on the contrary, they will resent it. Form deep stations and with the bottom mix the manure, and above that put

a 6-inch layer of the finest fresh soil at command. The roots quickly secure a hold, and later, as progress is made, the plants derive immense benefit from the excellent food put down below. There is no fear of its loss in so long a season of growth as the Dahlia demands; in fact, it is the other way about, since Dahlias will exhaust the supply before the end and will require special assistance from the cultivator.

The Stakes.—When Dahlias are admirably grown in excellent soil, they make plants which offer enormous resistance to the wind, and as the shoots are always brittle, there is serious danger that there will be disaster unless the staking is

of June, the results will be perfectly satisfactory, provided, of course, that all other essential details are correctly carried out. The plants are decidedly tender, and even when protection is afforded it is difficult, and sometimes quite impossible, to prevent a check to advance, and this is in no sense desirable. With plants that have been thoroughly hardened and are splendidly rooted, the work may be done at discretion, but dull, showery weather is most conducive to success. J. H.

AURICULA FLAME.

If there was one Auricula which by virtue of its brilliant colour stood out from all others at the recent Auricula show held at Vincent Square, it was the variety Flame. It was shown in Mr. J. Douglas' winning exhibit in the well-contested class for twelve Auriculas, dissimilar. It is a typical show variety, with broad banded petals, and paste on leaves and flowers. The colour, which is the remarkable feature of the variety, may best be described as a brilliant ruby crimson, and of a vivid glow that made it conspicuous among all other varieties.

TULIPS AT VINCENT SQUARE.

MAY 14.

No account of the display of Tulips in the Hall on May 14 would be complete without a few words by way of preface, on the eternal subject of the weather. It would be unseemly for me to describe it; but as the late Archbishop Magee said, when some footman anointed the episcopal coat with soup, "Will some layman please make an appropriate remark?" There were unmistakable signs of what the flowers had gone through, not the least significant being the empty benches which had been reserved for the competitive displays of "Cottages" and "Darwins," which one fondly hoped were going to initiate a long series of friendly contests among the amateur Tulip-growers of Great Britain. Oh! Mr. Curtis, why did you not bring some of those three hundred fine flowers you left at home? Oh! Mr. Faudel-Phillips, why did you not find it in your heart to cut just two or three dozen from that glorious display at Balls Park? Surely they would never have been missed! Canon Fowler and Mr.

Morton had the best intentions possible, but "fire" and an unkindly soil had defeated them. A seasonable toast, good readers: "Another year, another weather and some competitors." Enough of the show of empty benches, euphemistically called on this occasion "Tulips."

As the blackest cloud always has a silver lining, so these desolate, untenanted spaces had a brilliant and varied surrounding of fine groups and isolated vases, which for a time turned the large Hall into a delightful fairy-land of gorgeous colour. I cannot recall the time when there were so many large

SHOW AURICULA FLAME, A BEAUTIFUL VARIETY WITH RUBY CRIMSON FLOWERS.

done with care and efficiency. The one principal support should be placed in position immediately the preparation of the station is completed, and not afterwards, as is sometimes done by the novice. Driving down a stout, pointed stake when planting has been accomplished is an error that causes injury to the roots, and the results are thus prejudiced from the outset.

Planting.—In some districts planting will have commenced, but one gains little by over-haste and runs risks that are not worth accepting. If the whole of the work is finished by the middle

trade exhibits exposed to view at once. Sutton's, on the right hand of the door, under the able generalship of Mr. White, had a splendid collection of good varieties beautifully staged and excellently grown (not, by the way, in Holland, as a friend suggested to me, but at Reading). Carters occupied their accustomed place immediately facing the entrance, with a bold arrangement in big, tall vases, in the centre of which was a mass of what was the undoubted novelty of the show—the white, branching Tulip, M. S. Mottet, raised by M. Bouy in France, and to whom the scientific committee gave a certificate of appreciation when, on his behalf, I placed some growing in pots before them. As I am probably the only person who has a good-sized bed of them in his garden, I would like to say that I have found the branching to be constant, provided the bulbs are liberally treated and only the biggest ones planted, and that the irregularity in the size and development of the blooms and the length of the stems make a decided and pleasing alternative to the soldier-like regularity of the ordinary display. Messrs. Hogg and Robertson had a fresh and varied assortment from "Holland in Ireland." They can get fine blooms over there, and no mistake. Millet (rich crimson) and Herta (after *Pride of Haarlem*) were both good. Wales was quite the equal of Ireland in tint and size, and in the person of Mr. Watts showed what the gallant little land can produce. His *Baronne de la Tonnyne* must have been about the high-water mark of what the flower is capable of doing. His *The Fawn* was also excellent.

To me Dobbies is Cuthbertson—Sweet Peas and Potatoes. I will have to add Tulips soon I hope. They had a grand lot of Sweet Peas—beautifully grown, it almost goes without saying—but I was hardly prepared for their Tulips. Poor things! Mr. Ireland had stuck them away right at the back in two somewhat hard and stiff lines, as if he were afraid his old favourites might be jealous of them were their charms more attractively displayed. Possibly he was right, for in freshness, size and colouring the Tulips here had no superiors, if they had any equals, in the Hall; but it is only fair to state that they had passed the last week of their life under the kindly protection of a glass light. Lucky Ireland! he covered them in the nick of time. He put the lights on on April 9, and on the 11th there was a severe hailstorm.

Messrs. R. W. Wallace of Colchester exhibited several good new varieties. Grenadier, a large vermilion self; Quantness, faded mahogany with coppery yellow edge; Boadicea, a very large flower, dull mahogany red, edged orange, very like *Hammer Hales*; and Beauty of Bath, a very pale Fairy Queen, were four prominent ones. A small collection from Mr. C. Bourne was very attractive. I noticed here *Solfatare*, the beautiful pale yellow sport of *Fulgens*; that acme of refinement, *Louis XIV.*, deep rich purple with golden bronze edges; and Mrs. W. O. Wolseley, one of my own finds in a cottage garden about a mile from my home, and which I always claim as one of the hardest of

Tulips—it is a long, pointed, medium-sized flower of deep rich crimson. Mr. S. T. Wright, the superintendent at Wisley, told me it had stood the rough weather wonderfully well, and is one of the very few unspotted ones at Wisley, where it has been much admired.

Messrs. Barr and Sons were at one end of the hall, and had a large display. On the whole their flowers were on the small side, or they would have had a higher award. Prominent here were *Fontanelle*, a dull ruby rose Darwin, very distinct; *John Ruskin*, the beautiful art combination of salmon pink, pink and yellow; *Emerald Gem*, an orange rose with an olive green base, lovely and distinct in the garden; *Panorama* (also called, curiously enough, *Fairy*), an immense orange crimson; and *Flamingo*, the long pale rose and pink Darwin.

Messrs. R. and G. Cuthbert had a large display, but of uneven quality. I thought they would

Messrs. R. H. Bath's collection was very representative. Among the many good things was the lovely Darwin, *Massenet*, which was the only Tulip to gain an award of merit at the committee meeting. It is a flower well apart from others in its colouring; pale soft rose, edged warm flesh, with a conspicuous deep blue base, as near as I can get in my description. *Melicette*, one of my favourite mauves, and the rich rosy red *Orion*, one of the red Darwins I like so much, took my eye. I also noticed *Admiral Kingsbergen*, one of the most effective of all broken red and whites, and *Miss Doris Diggle*, a bright little striped bloom with maroon and lemon colouring. Mr. Leak tells me he has some fine stocks of these refined Tulips at Wisbech, and that he thinks the tide is turning in their favour. It has already done so in America, and buyers from Uncle Sam are rather keen after them.

HELICHRYSUM BELLIDIOIDES, A CHARMING LITTLE EVERLASTING FLOWER FOR THE ROCK GARDEN.

(See page 254.)

have had a higher award, but their little joke was lost on the judges. Brother (Fra) Angelico was either made into a woman or given a wife, for there he was labelled "Fra Angelica." Dom Pedro here was excellent. I have grown it for years, but its quiet beauty was lost on me till I saw a bunch of it pot-grown on Messrs. Sydenham's stand at the Birmingham Show. "Union Jack is lovely," one lady said to another as I was standing taking notes. It is a broken "byb," rather pale in shade.

Messrs. James Veitch and Sons displayed a very interesting collection. To me it was particularly so, as I expect for the first time in his life "Sir Harry" appeared in public as a Tulip. There is a good illustration of it in my book on Tulips. Suffice it to say now it is a large flower of a pretty shade of heliotrope pink, distinct and sturdy in a garden.

My last words are to record the small and diversified collection from the new venture, the Wargrave Plant Farm. I liked the mauve *Glory of Walworth* very much. A pure white base does set off a flower, and gives it a look which nothing else does.

Before buying-time comes round I hope to give, with the Editor's permission, a series of selections, for one has only to go to such a show as that about which I have been writing to realise the bewildering immensity of choice which to-day is ours.

JOS. JACOB

A USEFUL PLANT FOR CUTTING.

(*TUL CUPIDONE*)

THE *Cupidone*, as *Catananche carulea* is popularly called, was in olden times employed to induce love, and the name of *Catananche* is said to be derived from two Greek words signifying compulsion,

the idea being that it had the power of causing an irresistible impulse to love. How it was so applied does not appear to have been handed down to these prosaic days of ours. It is as a garden flower, however, that it is prized in our times, as its flowers are invaluable for cutting. The Cupidone is, however, not too hardy, and should have a dry soil and a sunny position, where it will generally thrive for a considerable number of years. The flowers, which are borne in August and September, are of a nice blue, but there is a white variety, alba, and one with white and purple blooms called *C. c. bicolor*. Seeds may be sown in spring in the same manner as those of other perennials and treated similarly.

S. A.

ROCK AND WATER GARDEN.

AN EVERLASTING FLOWER FOR THE ROCK GARDEN.

(HELICHRYSUM BELLIDIODES.)

THIS dainty little New Zealand plant, with its Daisy-like blossoms of about half an inch in diameter, is an excellent subject for the rock garden, and worthy of the award of merit bestowed upon it by the Royal Horticultural Society some weeks ago. The flowers are pure white, with a greenish yellow disc, and borne in great profusion on stems 3 inches or 4 inches above the prostrate growths, with small, ovate, entire leaves. It appears to be quite hardy, the illustration on page 253 being taken from a plant that has been growing on an exposed part of the rock garden at the Botanic Gardens, Cambridge, for the last two winters without having been affected in the slightest. It succeeds in a good, gritty soil, and is readily raised from cuttings or by divisions, and will be a great favourite when it becomes better known.

F. G. PRESTON.

A BEAUTIFUL ROCK GARDEN VIOLET.

(VIOLA PEDATA.)

This is a very beautiful, but, at the same time, a notoriously difficult alpine to cultivate. This is admitted by everyone who has had any experience of its cultivation. It is of no use saying that its culture can be successfully attempted by using any special soil or situation, although it is said to thrive in pure sand in the higher altitudes here, and in the lower parts the addition of some loam and leaf-soil or peat to the sand is helpful. It occurs to me, however, that plants are often lost because they are given up as dead, whereas they are only taking a long rest. On May 1, on going through the alpines in the nurseries of Messrs. T. Kennedy and Co., Dumfries, along with Mr. Croall, who has charge there, the latter said he was afraid that *Viola pedata*, planted on a rockery

in September, was dead. On inspection, however, we found it just pushing through the soil, and apparently quite vigorous. This note may save many a plant, which, if left alone, might appear in due course. This is such a charming Violet, with its prettily-cut foliage and handsome lavender or blue flowers, white in alba, and with purple upper petals in bicolor.

Dumfries.

S. ARNOTT.

THE PERENNIAL CANDYTUFT.

The perennial Candytuft is foremost among effective rock plants that flower from May onwards

THE PERENNIAL CANDYTUFT DRAPING LARGE BOULDERS IN THE ROCK GARDEN.

When grown in a sunny position overhanging rocks, it is seen to advantage, for the patches of pure white flowers appear like drifts of snow in the distance. The perennial Candytuft is known botanically as *Iberis sempervirens*, and the variety, which differs but slightly from that species, illustrated on this page is known as *garrexiana*. For many weeks past these bold and free-flowering clumps have been a source of pleasure. This subject is both hardy and ever-green, and when once established will remain good for years. Young plants are easily raised from cuttings.

COLOURED PLATE.

PLATE 1472.

ROSE DANÆ.

THIS very pretty novelty belongs to a group, namely, the Hybrid Musk, that seems likely to become an important one in the near future. Although I do not know for certain, I assume *Danæ* originated from Trier, crossed probably with a yellow Polyantha. Certainly its raiser, the Rev. J. H. Pemberton, has succeeded in producing a very charming garden Rose, and it is to be distributed, I believe, by Messrs. Hobbies, Limited, in the autumn. The perpetual-flowering character of the Rose will give it an extra value, and its lovely yellow blooms will be greatly appreciated. I have had no opportunity so far of comparing the blooms of *Danæ* with a Rose already in commerce named *Thermidor*, but I believe there will prove to be a certain similarity in the flower, although *Danæ* is of greater vigour. With me *Thermidor* grows like a strong dwarf Polyantha, and it is very perpetual. I like it much, and intend to grow it largely as a big bedder. Of course, *Danæ* will be planted more as a free bush, just as we do Trier, and I expect it possesses the same delightful aromatic fragrance as the latter, which originated with Herr Peter Lambert. The Rev. J. H. Pemberton states that *Danæ* is good in autumn and mildew-proof. It received a silver-gilt medal from the National Rose Society in 1911, an award of merit from the Royal Horticultural Society in September, 1912, and a first-class diploma from the North of England Horticultural Society in August, 1912.

Messrs. Paul and Son have raised a very useful variety named *Queen of the Musks*, which will be welcomed for its fine bold effect in the garden. Adrian Reverchon hails from Trier, which is the German town where its raiser, Herr Peter Lambert, resides. It is a sort of perpetual-flowering *Hiawatha* of a climbing character. This should prove valuable, and we shall also be able to plant around it the new *Papa Heurcay*, a rather strong-growing dwarf perpetual Polyantha with large trusses of bloom after the style of *Hiawatha*. Geheimrat Dr. Mittweg is another of the Trier seedlings with a very free perpetual-flowering habit, and Schiller is yet another, having small, peach pink flowers.

It will thus be seen that the group is extending, and I for one welcome them, as they give us a race of Roses with a lovely distinctive perfume that reminds us in autumn of the June-time, when perhaps there are more of these distinctly-scented varieties in bloom.

DANECROFT.

New Perpetual Flowering Rose Dana.

REVIEW OF THE SPRING SHOW AT CHELSEA.

A GREAT and unqualified success best describes the magnificent spring show of the Royal Horticultural Society, which opened at the Chelsea Hospital Grounds on Tuesday last. Hitherto, as most of our readers are aware, this exhibition has been held in the gardens of the Inner Temple, on the Thames Embankment, and it was with considerable reluctance that the Council had, owing to the rapidly-increasing number of exhibits, to move to the more spacious grounds at Chelsea. That the move was fully justified the magnificent exhibition now under review fully proves. The number of exhibitors on the present occasion is nearly twice as many as the largest number at any Temple Show, and the exhibits may fairly be regarded as representing the highest and best forms of gardening. The Old English gardens and the rock gardens are in themselves beautiful features, and the interest taken in the former would lead us to believe that there is an increasing tendency to revert to this form of gardening in place of the more natural style that has for so long held sway. That formal gardening, as it was known in the sixties of the last century, will ever replace natural gardening we do not for one moment believe, nor would we wish it; but there is no gainsaying the fact that such gardens as those exhibited by Messrs. Wallace and Carter are quite in keeping with many old mansions. The arranging of all pot plants and cut flowers in one large tent is an excellent idea, but the gangways might well have been wider. Queen Alexandra, accompanied by Princess Victoria, visited the show on the opening day, and spent some time admiring the many beautiful flowers and gardens. In the pages that follow will be found a review of the principal exhibits, with illustrations of some of the most noteworthy.

In the preparation of this special number we have been greatly assisted by various members of the Council; by the secretary, the Rev. W. Wilks; the superintendent of the show, Mr. S. T. Wright; Mr. Frank Reader and other officials, and to these we tender our best thanks. Without their help it would have been impossible to have placed before our readers an illustrated

and planted with the choicest of alpine vegetation, and, withal, so endowed for the most part with the atmosphere of mountain plant-life that we might be pardoned for believing them to be a true bit of such scenery. Hence the object of their being is achieved; the teaching value is sound, which, after all, is the one great reason for holding such exhibitions at all. Our only regret is that they are so numerous and good that we are unable to deal with them all. They are arranged near the Embankment.

Messrs. Wallace and Co., Colchester, who led the way last year by raising the finest rock garden ever seen at an exhibition, have this year a fine piece of rockwork in conjunction with a sunk garden, wall garden and garden-house. The latter is remarkably well done, the old, stone-tiled roof affording much proof of true and thoughtful work. A fine stretch of water, or rock garden pool, and the paved ways with their complement of little things will appeal to all. Choice conifers and alpinas abound in every direction, suitable colonies of plants appear near the water's edge, and anon elsewhere. The stone is particularly good and well chosen, and our readers are directed to examine it with care. Some three thousand square feet are devoted to it.

Mr. G. Reuthe, Keston, Kent, relies rather on the choiceness of the material he employs than on any elaborate piece of rockwork. On this occasion, however, he has a nice arrangement of the latter, and has arranged some pretty plant colonies thereon. Of these, *Helichrysum triunervis* is a fine plant and a good grower, *Æthionema pulchellum* is charming, while such as *Pyxidantha barbulata*, *Lewisia* of sorts, *Trilliums* and *Edraianthus serpyllifolius* are all things to seek for and admire.

Mr. Clarence Elliott is near by, and has done the best piece of work we have seen from him. His colouring in some instances is admirable, and so fine a patch as *Aquilegia Stuarti* will need no finding; it is there, and will appeal by the great picture of blue and white it creates. It is in the highest degree superb, a worthy plant worthily treated. Next to this our readers should look for *Saxifraga*

QUEEN ALEXANDRA AT THE OPENING OF THE CHELSEA SHOW.

and comprehensive review of this magnificent show in so short a time.

ROCK AND FORMAL GARDENS.

If in rock gardening the great International Show held last year at Chelsea was in the nature of an "eye-opener" to all interested in this rapidly-growing fascinating phase of gardening—unique, indeed, in the annals of horticulture—the rock gardens to which we to-day direct our readers' attention will play a good second. Not a few of them, indeed, are works of art, carefully arranged

PART OF THE BEAUTIFUL ROCK GARDEN SHOWN BY MR. J. WOOD,
BOSTON SPA.

Aizoon rosea; it is there also, delightfully arranged, and demonstrates rock garden grouping *par excellence*.

Messrs. R. Tucker and Sons, Oxford, are responsible for a quite small exhibit, and things to be looked for are *Androsace arachnoidea*, *Anemone alpina*, *A. sulphurea*, the pretty *Stachys corsica* (unimitable among carpeters) and *Oenothera ovata*.

Exactly opposite this, with, as we thought, an all too thin dividing line, is a rock garden from the Burton Hardy Plant Nursery, Christchurch, and here were noted many beautiful *Primulas*, not least of these being *P. Lissadell Hybrid*. *Sedum pilosum*, too, is most interesting, while *Lewisia Cotyledon*, *Ranunculus* and *Cistus purpureus* are worth seeking.

Messrs. Piper and Sons, Barnes, have a much more elaborate rock and water garden, covering 3,000 square feet, and the work is well done. At or near the water's edge great groups of *Trillium*, *Cypripedium*, *Sarracenia* and *Primulas* may be seen, *Funkias*, too, forming handsome foliage groups. Good bits of colour are afforded by *Primula cockburniana*, *Incarvillea grandiflora* and *Campanula Steveni nana*, a delightful carpeting pale blue *Bellflower*. Shrubs, flowering and otherwise, are on the banks and slopes, and add materially to the good effect.

Messrs. Carter, Raynes Park, are responsible for a clever piece of wall and formal gardening, the former deftly planted with very choice things. The one side—the main entrance we should say—is by a hammered iron gateway from the great avenue, and here at once visitors are in touch with terrace garden and fountain, with *Columbines* and *Primulas* in the shadier parts. By steps right and left the visitor gets to the lawn and the sumptuous borders of *Azaleas*, *Rhododendrons*, *Primulas* and other plants which lend their brilliance around. The whole is delightfully arranged, and is certainly one of the features which must not be missed.

The Guildford Hardy Plant Nursery have an admirable rock garden exhibit, and not a few of the choicest alpins. For example, no one should miss the rare assortment of

alpine *Erodiums*; *olympicum*, *supracanum* and *chrysanthum* are some. None can miss *Celmisia spectabilis* or the mass of *Incarvillea brevipes*, which is a big rival to *I. grandiflora*. The finest bit of colour, however, comes from the brilliant *Ourisia coccinea*. The lovely patch of it is a show in itself.

Messrs. Whitelegg and Page, Chislehurst, near by, have a magnificent piece of work. Their new orange yellow *Geum* John Bradshaw is alone a gem, while *Cotyledon spinosum*, *Wahlenbergia vincaeflora* and *Primula cockburniana* will appeal to all. Very fine in contrasting effect are the white *Meadow Saxifrage*, *S. granulata plena*, and the scarlet-flowered *Habranthus pratensis*.

Messrs. J. Cheal and Son's formal garden and rock garden are on the opposite side of the roadway, the rock garden being formed in a depression. It is full of interesting and showy subjects, and

must be entered and examined to get even a glimpse of what it contains. Alpines, however, abound, while choice shrubs and other things play their part in the more formal work.

Mr. Maurice Prichard, Christchurch, has an elaborate rock garden in Purbeck limestone, though his choicer things go to make up a bit of moraine gardening which is not placed on the front-door steps. In other words, our readers must "walk in," and *Pentstemon caruleus*, *Lewisia*s of sorts, *Silene Hookeri*, *Oxalis adenophylla* and much more will be revealed.

Messrs. Barr and Sons, Covent Garden, have, right at the entrance to their rock garden, which is of 1,000 square feet, a fine subject in *Aster Falconeri*, with *Cytisus Beauii* (yellow) at its feet. *Orchises*, *Primulas*, *Cypripediums* and *Rodgersias* are either in the water or at its margin.

Quite on an elaborate scale will be found the rock and water garden arranged by Messrs. Pulham and Sons. It is admirably executed in mountain limestone and suitably planted in every part. *Saxifraga peltata* is notably good in flower, and colonies of *Primulas* may be seen in plenty.

If we say at once that the arrangement of mountain limestone, covering a space of 2,000 square feet, set up by Mr. J. Wood, Boston Spa, constituted the truest imitation of Nature of any rock garden in the whole show, it is to give our readers a finger-post to guide them. Magnificently weathered, designed to suit the most exacting landscape gardener or geologist, it is above reproach, the array of good plants it contains appearing as suitable garniture. True to Nature, it is, so far as it goes, the finest thing we have seen in this respect. There is great teaching value in it, and our readers must note accordingly.

Messrs. T. S. Ware, Limited, Feltham, have an excellent rock and water garden on a large scale. *Sedum pilosum* is very fine, also white and coloured *Ranunculus*, *Silene Hookeri*, *Cypripediums* and others.

Messrs. William Cutbush and Sons, Highgate, display particularly fine groups of *Lilies*, *Anemone sulphurea*, *Lewisia leana*, *Incarvillea grandiflora*, *Primula pulverulenta* and the lilac-flowered *Daphne Genkwa*. *Lilium colchicum* is very handsome and in fine array.

A NOBLE ARRANGEMENT OF ROCKWORK, WITH WATERFALL, IN MESSRS.
PULHAM'S EXHIBIT.

Messrs. Bickhouse and Sons, York, occupy 1,000 square feet, and with well-toned sandstone have arranged a fine piece of rock gardening. *Ramondias* and *Haberleas* are very beautiful on shady slopes. *Anemone sulphurea* is superb, and equally so *Orchis foliosa*. Quite a wealth of other good plants are to be seen, and some fine water effects also.

The Craven Hardy Plant Nursery, Clapham, Lancaster, will be found among those who rely on choice plants—in this case the choicest to associate with good rock gardening—but they are too numerous to mention in detail. We must, however name some—the inimitable *Daphne rupestris*, which we remember for nearly a dozen years in succession at the Temple; *Ramondia Natalia* alba (exquisitely beautiful), *Campanula alpina*, *Primula glutinosa* and *Ranunculus parnassifolius*. Of course, Mr. Farrer has got *Edraianthus serpyllifolius major*, and by the hundreds on this occasion. It is in its prime, too, and its trails of imperial purple are rich indeed.

Messrs. Bees, Limited, Liverpool, have some of the choicest new alpinas in the show. These will be found in the large tent high up near the hospital end. *Rosecea caulioides* (yellow), *Pentstemon caruleus* (true), *Primula secundiflorus* a wine-coloured *sikkimensis*, *Oxalis adenophylla*, *Dracocephalum bullatum*, *Celmisia spectabilis argentea* and a large number of rare *Primulas* must be sought out. They exist nowhere else.

Mr. H. Hemsley, Crawley, has a table of interesting alpinas and shrubs, *Ourisia*, *Onosma*, *Cornus canadensis* and *Achillea Aizoon* being good.

Mr. Reginald Prichard, West Moors, Wimborne, will also be found high up in the big tent revelling in the choicest of alpinas, of which he appears a veritable purveyor. His well-flowered mats of *Campanula Stevensii nana* will never be forgotten if seen, nor the spreading carpets, 18 inches in diameter, of *Helichrysum bellidioides* (white flowered), which have never before appeared so fine. *Dianthus Prichardii* is a novelty and a gem. *Edraianthus calycinus* is a great rarity, and *Linum capitatum* is choice.

The Misses Hopkins, Shepperton-on-Thames, have pretty groups of alpinas on rockwork, also under canvas, the group being rich in *Primulas*, together with *Oxalis enneaphylla*, *Daphne Cneorum*, alpine *Phloxes* and the like.

Messrs. Kent and Brydon, Darlington, have particularly good examples of *Gentiana bavarica*, also a variety of *Cypripediums* and *Primulas* in conjunction with showier things.

Messrs. Thomson and Charman, Bushey, Herts, have a most valuable plant in *Lewisia columbianum*. It is superbly flowered and the finest example of the species in the show. *Geum Borisi*, *Campanula Stevensii nana*, *Viola corsica*, and good *Ramondias* are worth looking for.

Mr. Stuart Maples, Stevenage, has a variety of alpinas on table rockwork. We believe this exhibitor appears for the first time.

ROSES.

The sense of overcrowding so often manifest at the Temple Shows of the past is entirely absent at the delightful exhibition now on view at the Chelsea Gardens, and in no respect is this more manifest than in the grouping of the Roses. Each exhibitor has seized his opportunity and made the most of it, and the difficulty is to so appraise the merits of the individual groups as to place them in order of merit. As these notes are penned before the judges' awards have been made known, we should say that the judges cannot well pass over for premier place the noble group from Messrs. William Paul and Son of Waltham Cross. Mr. Miller, the able grower, has timed his plants to a day, with the result that we have here on view a most delightful and representative group, consisting very largely of the firm's own novelties. Huge pillars of the *White Tausendschön* are to be seen alongside the lovely and original *Pink Tausendschön*, and it cannot fail to catch on as one of the best

Another notable group is that of Messrs. George Mount and Sons, and here we have perhaps the most perfect quality of the old standard sorts that it is possible to conceive. Surely, not even at Chelsea last year, were the Mrs. John Laings of such surpassing quality as now, and they are worth a journey to see them, even were there nothing else to see in this floral Paradise. Then, the Mrs. George Shawyers are grander than ever, and one is not surprised our American cousins are going crazy over this lovely Rose. Huge mounds of *Lady Pirrie*, *Irish Elegance*, *Ulrich Brunner*, *Frau Karl Druschki*, *George C. Waud* and *Sunburst*, edged by the delightful *Flower of Fairfield* in small pots, complete a very splendid group. This latter is the perpetual form of *Crimson Rambler*, and as a dwarf pot plant it far outshines all the red *Polyanthas*.

Messrs. Paul and Son, Cheshant, have, as is their wont, a very fine group, in which standard weeping Roses are very prominent. We thought

PART OF THE OLD ENGLISH GARDEN, SHOWING THE GARDEN-HOUSE, EXHIBITED BY MESSRS. R. WALLACE AND CO.

ramblers hitherto produced. Another fine Rambler is *Sylvia* (pure white), and it is perpetual-flowering and fragrant, most desirable attributes. The pillar and standard ramblers are most gorgeous in their varied tints, and consist of such fine things as *Excelsa*, *American Pillar*, *Hiawatha*, *Coquina*, *Lady Gay*, and the new *Lady Blanche*; this is a perfectly dead white, which will make it of greater value than the so-called white sports of *Dorothy Perkins*, which frequently have pinkish tints. Of the decorative and show Roses the following are splendid: *Ophelia*, *Marcella*, *Margaret*, Mrs. Charles Hunter, *Lady Downe*, *Dora*, *Juliet*, *Portia*, and Dr. William Gordon, all of the firm's production; and besides there are such notable kinds as *Rayon d'Or*, *Sunburst*, *Mme. Lutaud*, *Souvenir du Gustave Prat*, Mrs. Foley Hobbs, *Commandant Felix Faure*, Mrs. George Shawyer, *Phariszer*, *Entente Cordiale*, Mrs. Aaron Ward, and *Mme. Maurice de Luze*.

the group a little too crowded perhaps, but yet it contains some very choice things. The pretty dual weeper of *Milky Way* and *Hiawatha* may suit the taste of some individuals, but, generally, it is not admired. *George C. Waud* is very fine; so also are *Freda*, *Magnolia*, *Lady A. Stanley*, *Laurent Carle*, *Souvenir de Gustave Prat*, *Mme. Second Weber* and *Marquise de Sinety*.

All Rose fanciers must see the fine group of novelties from the renowned raisers Messrs. Alex. Dickson and Sons of Newtownards. Messrs. Dickson have brought together one of the finest lot of novelties they have ever put up, and it cannot fail to be an attraction throughout the show. *Queen Mary* is a lovely gem and is difficult to describe. It has wonderful rainbow tints and such delicious fragrance. *Verna McKay* is a gem of the first water, with its amber tints and lovely elongated buds, *Carine*, so sweetly fragrant; *Irish Fire-Flame*, a copper-coloured *Irish Elegance*; *Alexandre*

PART OF MESSRS. J. CARTER AND CO.'S OLD ENGLISH GARDEN.

Hill Gray, Duchess of Westminster, Lady Plymouth, Mrs. Wemyss Qum, a sort of deeper Rayon d'Or; Mrs. Cornwallis-West, Mrs. Campbell Hall, and Mrs. Forde are other fine blooms; while a box of Mrs. Foley Hobbs is one of the finest things in the whole show, one flower especially attracting the envy of every Rose exhibitor. There are two delightful crimson seedlings unnamed, and a grand lemon novelty named Mary Green, which we are likely to hear much of.

A superb group comes from Messrs. B. R. Cant and Sons of Colchester, in which we find splendid masses of St. Helena and Sallie, two really good things that everyone must have. Sunbeam is a lovely colour, reminding one of Mrs. A. R. Waddell; Elizabeth, Lady Reay and Rose du Barri are also fine. Silver Moon is a charming single Rambler with huge flowers not unlike Simplicity, and one can imagine the beauty of such a Rose when on a pergola. Garisenda is a fine big-flowered Rambler, and Aviateur Blériot a lovely orange-coloured wichuraiana of a most unique shade.

Messrs. Hobbies and Co. of Dereham have a novel group, consisting largely of a pergola well covered with ramblers. Pretty baskets add a charm to the group, and these are filled with some of the firm's own novelties, such as Dewdrop and Baby Elegance. Pink Pearl is a pretty Rambler; so also is the Double White Rambler, a seedling of Crimson Rambler, raised by the Rev. J. H. Pemberton. Its delicate pink buds will be admired by many. Danæ is a lovely gem for the garden, and Miss F. Mitford, a semi-double seedling of Rosa Brunonis, will be a good addition to garden Roses.

Messrs. Cutbush and Son of Highgate are strong in Polyantha and Rambler Roses, and a very charming group it is, which well displays the usefulness of the Polyantas as decorative subjects. Practically all the best kinds are represented, not in single plants, but in fifties or more. Baby Tausendschön is lovely; Jeanne d'Arc and Yvonne Rabier, two fine whites; Mrs. Cutbush, Jessie, Ellen Poulsen, Perle d'Or and Mme. N. Levavasseur are all here; while delightful masses of Tausendschön, Dorothy Perkins, American Pillar and Newport Fairy complete a very fine group.

Messrs. George Beckwith and Sons of Hoddesdon have a group that we venture to say will be a centre of attraction, for it contains some fine masses of the sensational Rose Mme. Edouard Herriot, which, as all the world knows, is one of the latest introductions of M. Pernet-Ducher. Willowmere, the improved Lyons Rose, is also shown in great force, and it is certain to become a favourite; while a vase of Cissie Easlea portrays what a grand novelty we have in this variety of the Pernetiana class. A number of pots of Papa Hemeray is a pretty feature of this group. It is like a large flower of Hiawatha, only of dwarf growth and perpetual.

Messrs. Frank Cant and Co. have a sumptuous group of good things, including many fine show blooms. Lady Alice Stanley, Mrs. John Laing, Mrs. George Shawyer, Richmond, Mrs. D. Jardine, and Lady Roberts are very fine, and there are numerous kinds to be found in smaller quantities. The quality is excellent throughout this fine group.

Mr. Charles Turner of Slough has a very elegant group of standard weepers, with a groundwork of Polyantas. Some grand examples of Coronation and Ethel display what two fine novelties we have here in ramblers, and so perfectly distinct.

Messrs. Low and Co. have a pretty group, chiefly in Bamboo stands, and the quality is excellent. Lady Hillingdon, Molly Sharman Crawford, Lady Pirrie, Sunburst, Joseph Hill and Mrs. George Shawyer are very lovely.

Mr. George Prince of Oxford has huge mounds of ramblers and Polyantas, and if we miss his glorious Tea Roses, we must wait until the outdoor crop comes on for these. A grand mass of Hiawatha is most showy, and American Pillar, Blush Rambler, Lady Godiva and White Dorothy are also fine, together with Ellen Poulsen, Jeanne d'Arc and other good Polyantas.

Messrs. Robichon of Orleans are showing a yellow seedling after the Rayon d'Or type, but not nearly so good and certainly not wanted.

Messrs. A. J. and C. Allen of Norwich have a small but attractive group of good things, and perhaps the Rayon d'Or here are as good as any in the show.

Messrs. R. J. Barnes and Son of Malvern have a small collection of very good flowers.

Mr. Walter Easlea of Danecroft Rosery, Eastwood, Leigh-on-Sea, has a very pretty group of his new Polyantha Rose Susie, a charming peach pink flower of delightful form. It will certainly prove a worthy addition to this popular class.

Outside, in the grounds, many of the exhibitors of sundries are freely employing Rambler Roses, perhaps the best exhibit being that of Messrs. William Wood and Son. The ramblers here show up grandly against the pergola columns, and cannot fail to give a stimulus to this class of plant, if any were required, and we shall all welcome the day when raisers produce some really perpetual-flowering forms that are equal in every respect to the superb varieties now in commerce which are, unfortunately, summer-flowering only, or at least the majority of them. We can safely assert that, were there nothing but Roses at this grand show, they would be well worth the journey to see, and our hope is that the exhibition will prove a huge success, for probably no finer show of mainly British productions has ever been placed before the public.

STOVE AND GREENHOUSE PLANTS.

Messrs. James Veitch and Sons, Limited, Chelsea, exhibit a splendid group, consisting for the main part of stove foliage plants, lit up by the bright tints of the Crotons and Caladiums. A choice collection of flowering subjects is also associated therewith, prominent among them being Kalanchoë flammea, Anthuriums in variety, and an extremely choice selection of Orchids. Of the foliage plants especial mention may be made of Croton Dayspring, F. Sander, Golden Ring and Baron A. de Rothschild. Two particularly striking subjects are Cyanophyllum magnificum and Coccoleba pubescens, this last having large, almost round leaves of a firm, leathery texture. In another place Messrs. Veitch are showing a charming selection of greenhouse flowering plants, notably Cinerarias in great variety, Gloxinias, Streptocarpus, Calceolaria Chirami, Streptosolen Jamesonii and Elæocarpus reticulatus, which they grow well. There is a fine and representative group of their strain of Hippeastrums, for which they are justly famous, and disposed above these are a number of cordoned plants of Fuchsias, which serve to show the suitability of these plants for training to the roof of a greenhouse.

Messrs. E. Webb and Sons, Wordsley, Stourbridge, make a very imposing display of different flowering subjects raised from seed. Against one side of the tent they have huge hemispherical groups of Calceolarias, Cineraria stellata, Schizanthus, Begonias, with Petunias, Gloxinias, hybrid Impatiens, Salvias and others.

Messrs. Sutton and Sons of Reading have a very fine exhibit, the plants composing it being arranged in several beds. Particularly noticeable are the Reading strain of Cineraria stellata, as well as a pleasing variety known as Reading Gem. A bed of Schizanthus includes the finest forms in the entire genus, while all that can be said of the Nemesis, Stocks, Begonias, Primula obconica and Gloxinias is that they all well uphold the great reputation that the firm enjoys. The central figure of their group is a mass of Clarkias, among which the variety Firefly is in its way unsurpassed.

Messrs. James Carter and Co. of Holborn and Raynes Park also show a group of flowering plants that can readily be raised from seed. Their principal feature is a magnificent display of *Cinerarias*, though the *Gloxinias* and *Stocks* are also very fine. The beautiful rich green of the turf in which the flowers are set serves to enhance their beauty. This same remark also applies to Messrs. Sutton's exhibit.

A large and varied collection of flowering plants comes from Messrs. Stuart Low and Co. of Bush Hill Park, Enfield. Included among them are many *Heaths*, *Boronias*, *Aphelexis* and other hard-wooded plants, while towering above them are tall plants of *Acacia pulchella* and standard specimens of the *Bottle-Brush Flower*, *Callistemon salignus*, better known as *Metrosideros floribunda*. Other notable features of Messrs. Low's exhibit are some splendid blue *Hydrangeas*, *Gerbera* hybrids, the distinct and pleasing *Araucaria Silver Star*, and *Leptospermum scoparium Nicholli*, which was given a first-class certificate last year at the "International."

Messrs. William Cutbush and Sons of Highgate also show a varied group, consisting of hardy *Azaleas* and *Rhododendrons*, with a great number of greenhouse flowering plants. The dominant feature of this exhibit is the collection of *Hydrangeas*, of which many varieties are shown, including some of the latest kinds. One bearing the outrageously long name of *Générale Vicomtesse de Vibraye* is remarkable from the fact that, though naturally of a bright rose colour, it acquires a more decided blue tint than any other *Hydrangea*. Messrs. Cutbush have a preparation of their own, known as "Azure," for turning *Hydrangeas* blue, and the condition of those shown says much for its effectiveness.

Messrs. Charles Turner and Sons of Slough show some Indian *Azaleas* trained in the strictly pyramidal manner that was at one time so popular. They are interesting as showing the way in which these plants were in the older days largely grown. Arranged with some bush plants, *Malmaison Carnations* and *Ferns*, a very pretty effect is produced.

Messrs. John Peed and Sons, Roupell Park Nurseries, Streatham, show a fine collection of very large specimens of *Caladiums*. Prominent among them are *Triomphe de Comte*, bright red; *Candidum*, white; *King George*, rose, freckled red; *Diamantina*, white, green and red; and *John Peed*, rich red. Besides the *Caladiums*, Messrs. Peed contribute a large and representative group of their noted strain of *Streptocarpus*.

Seented-leaved *Pelargoniums* are certainly making great headway in popular favour. Miss Trovte Bullock, North Coker House, Yeovil, Somerset, has a collection of no fewer than 140 distinct varieties, a fact of which she may justly feel proud.

From Aldenham House Gardens comes another fine collection, which, though more limited in numbers, makes an imposing show, owing to the plants being all good-sized bushes in pots 7 inches or 8 inches in diameter. In this collection some seventy or eighty varieties are shown.

Rolls Hoare, Esq., West Grinstead Park, Sussex, also contributes a good collection of this class of *Pelargoniums*, about a hundred being represented among them. In all the exhibits the bulk of the plants are in flower.

Pelargoniums of the Zonal and Ivy-leaved sections are shown in great variety by Mr. H. J. Jones, Limited, Hither Green Nurseries, Lewisham. The plants shown are good examples of culture, and a choice selection might easily be made from those shown.

As usual, Messrs. Godfrey and Sons, Exmouth, are staging a large number of decorative *Pelargoniums*, which they grow so well. The variety among them is great, and their dwarf habit and profusion of flowering are all that can be desired. Numerous other plants are shown by this Exmouth firm, notably a beautiful salmon pink bedding *Pelargonium*, *Duchess of Cornwall*, and the New Zealand *Veronica hulkeana*, whose lavender-coloured flowers are borne in great profusion.

A unique exhibit is that from Mr. Bruce, The Nurseries, Chorlton-cum-Hardy, Manchester. It consists of a group of insectivorous plants, mainly consisting of *Sarracenias*, though there are others. One pan of *Dionæa muscipula* is very striking. Many of the *Sarracenias* are splendid examples, perhaps the most striking of all being *S. Willmotta*, a hybrid kind. Lightness is imparted to this group by a free use of *Peltas* and *Eulalias*. A charming little creeping melastomaceous plant, *Heeria elegans*, with carmine red flowers, is freely represented in this group.

Mr. L. R. Russell of Richmond has a collection of choice *Caladiums* shown as small plants, arranged several together in large pans. In this way, looked at from above, they are most attractive. The new *Flora Russell*, a crimson-leaved variety, is especially noteworthy. Associated with the *Caladiums* are other choice stove plants, particularly *Marantas*, *Abocacias* and several examples of *Nidularium Meyendorffii*, remarkable for the brilliant colour of the central leaves.

The pigmy trees from Messrs. Barr and Sons are, as usual, much admired by those on the lookout for something away from the common. Though many of them are hardy, in their pigmy forms they need the protection of a greenhouse, or, at all events, a situation where they are protected from harsh and drying winds.

Messrs. Blackmore and Langdon, Twerton Hill Nurseries, Bath, have an exhibit that well upholds their world-wide reputation for tuberous-rooted *Begonias*. When so many beautiful kinds are shown, it is difficult to make a selection, but the following cannot be passed over: *Princess Victoria Louise*, which was last year given an award of merit, pale salmon pink; *Duchess of Cornwall*, dark crimson; *Rose Queen*, rich rose; *W. Marshall*,

scarlet; and *Mrs. Thornton*, white. The sturdy growth and erect flowers of the recent kinds show quite a wide departure from the tuberous varieties of old. Besides these, Messrs. Blackmore and Langdon are showing a new basket variety, *Mrs. Bowers*, whose blossoms are of a delightful shade of reddish salmon. It will prove a desirable addition to this valuable class. Two semperflorens hybrids, *Carmen* and *Pink Beauty*, are doubtless destined to be soon much better known.

Messrs. Thomas S. Ware, Limited, Feltham, have long been identified with the improvements in the tuberous *Begonia*, and their present exhibit is one of the best. It mainly consists of double-flowered varieties, with blooms as perfect as one may desire. Among the best are *Countess Cadogan*, orange; *Mrs. Justice Hodges*, cream, red picotee edge; *Lady Ebury*, deep rose; *Captain Lafone*, pink, much crisped; and *W. G. Valentine*, scarlet. *Lady Cromer*, one of the finest of the tuberous-rooted *Begonias* ever raised, and for which we are indebted to Messrs. Ware, is, as might be expected, very finely shown in their group.

Messrs. Robert Veitch and Son, Exeter, show a pretty and interesting group of *Calceolarias*, all raised by them. Prominent in this exhibit is the pretty cream-coloured, vigorous-growing *C. Veitchii*, which was given an award of merit last year at the "International."

A fine lot of *Calceolarias* of the herbaceous section is contributed by the Rev. H. Buckston, Sutton Hall, Derby, the flowers being particularly good and the colours well varied.

From Mrs. V. A. Litkie, Clarefield, Pinkneys Green, Maidenhead, comes a noble circular group of *Calceolarias*. The centre consists of large plants of *C. Chibranii* or *protusa*, and around the margin are beautiful specimens of members of the herbaceous section. Occupying the intermediate space are a number of crosses between the herbaceous kinds and *C. Chibranii*. These are in habit, size and colour of the flowers about midway between their parents, and are a decidedly promising lot.

Mr. Charles Turner, Slough, contributes a small but interesting group of *Pelargoniums*, among them being representatives of the show, decorative and fancy classes. These last were at one time extremely popular, but are now very rarely seen, their lack

A PORTION OF THE ROSE GROUP SHOWN BY MESSRS. STUART LOW AND CO.

of size being against them, according to present-day ideas.

From Mr. Victor Slade, Taunton, Somerset, comes a quantity of cut blooms of Zonal Pelargoniums, consisting of both single and double kinds. A good and representative collection.

In a group, mainly consisting of Carnations, shown by J. D. Webster, Chichester, is a magnificent lot of cut flowers of *Richardia Pentlandii*, which shows that their cultural requirements are well understood.

Messrs. H. Camell and Sons, Swanley, Kent, fill one of the tables with a selection of choice flowering subjects. Prominent among them are *Calceolaria Clibranii* (very much in evidence at the present exhibition), *Schizanthus* (a very fine strain), Pelargoniums of different sorts, but mainly of the decorative section, and herbaceous Calceolarias, the whole being finished off with a fringe of loose-growing Lobelias, which serve to prevent any bareness at the front. Good plants of *Grevillea robusta* also serve to take off any stiffness or formality.

From Messrs. Kent and Brydon, Darlington, comes a splendid bank of Lily of the Valley, both the foliage and the flowers being equally fine.

Aug. P. Brandt, Esq., Bletchingley Castle, Surrey, contributes a fine bank of decorative Pelargoniums, the selection being good, and the condition of the plants leaves nothing to be desired.

A miscellaneous collection of plants shown by Mr. G. Reuthe, Keston, Kent, is made up of a great variety of different subjects, some being hardy shrubs and many of a half-hardy character. Prominent in the exhibit are a great many different Rhododendrons, both Himalayan species and various garden hybrids.

The collection of Hippeastrums or Amaryllis set up by Messrs. R. P. Ker and Sons, Aigburth Nurseries, Liverpool, are representative of their well-known strain. Prominent in the exhibit are the following varieties: Magnificent (chocolate red, shading to white at the edges), Lord Roberts (orange scarlet, light centre), Magenta Queen (bright carmine rose), and Rosy May (deep reddish rose, shading to white at the edge).

Messrs. H. B. May and Sons of Edmonton are showing a varied collection of flowering plants which they do so well. Among them are Pelargoniums (including that scented-leaved variety *Clorinda*), *Salvias*, *Lobelias*, *Heliotropes*, &c. Foliage plants include a collection of *Coleus* and of tricolor-leaved Pelargoniums, which last are very rarely seen nowadays. Standards, too, now so popular, are represented by *Salvias*, Lemon-scented *Verbena*, *Fuchsias* and Pelargoniums.

FERNS.

The exhibit of Ferns staged by Messrs. H. B. May and Sons of Edmonton is well worthy of their great reputation, fully 1,000 square feet being filled with choice examples, every one of which shows

a very high state of culture. The bulk of the exhibit is made up of large specimens such as one rarely seen, and these of many of the choicest kinds. Of those that may be especially noted are *Davallias* (quite a representative collection), Stag's-horn Ferns (of which the same may be said), *Polypodium Knightii*, *Polypodium Videnii* (which was given an award of merit a year ago) and *Polypodium glaucum crispum* (remarkable for its beautiful glaucous tint). There is a fine group of that mossiest of all the mossy varieties of *Nephrolepis exaltata*, namely, *Willmottii*, which was last year given a first-class certificate. A plant of the interesting *Nephrolepis Marshallii compacta*, which before the advent of *Willmottii* was regarded as the extreme form, is shown for the purpose of comparison. The fine plants of *Lygodium* also form a notable feature in Messrs. May's collection. The said group is edged with a representative selection

ASTER PURDOMII, A NEW DWARF SPECIES FROM NORTHERN CHINA. SHOWN BY MESSRS. J. VEITCH AND SONS.

of the finest hardy Ferns, a class whose culture is now largely taken up at Edmonton. Not only is such an exhibit of great beauty in itself, but the masses of greenery serve as a foil to the brightly-coloured flowers in close proximity.

Messrs. Hill of Edmonton, whose fame as Fern-growers is widespread, are showing a steep bank of very beautiful forms, disposed in an extremely pleasing manner. The *Gleichenias* in this collection are very striking, as also are the *Davallias*, *Platyneriums*, *Polypodium Knightii*, *Polypodium glaucum crispum* and *Polypodium Schneideri*.

Mr. W. A. Manda, New Jersey and St. Albans, make a feature of his beautiful new Fern *Polypodium mandaianum*, which made its first appearance at the "International," and was given a first-class certificate later on at Holland Park. It is in every way an ideal decorative Fern for large specimens, the spreading fronds being of a firm, leathery texture that enables them to resist draughts well.

Mr. Amos Perry of Enfield contributes a fine group of hardy Ferns, many of which for beauty vie with the choicest exotic kinds. The beautiful leafage of all those shown forms a very striking feature. The different varieties of *Athyrium*, *Felix-foemina*, *Polystichum angulare* and *Osmunda regalis* are particularly fine.

ORCHIDS.

It is to the Orchids that many visitors make their way on entering the exhibition gates. There is a wonderful display to be seen, for leading growers from all parts of the country are showing, and the quality of the flowers is better than ever. High banks of gorgeous Orchids create colour-schemes of bewildering beauty. Among the newer varieties *Odontiodas* are well to the fore, while *Miltonias*, which eight or ten years ago were thought little of, are now favourites among the Orchid-loving public.

A collection of *Cattleya* hybrids, in perfect condition, comes from Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Gloucestershire. Large pans of the lovely *Cattleya Skinneri* and innumerable *Brasso-Cattleyas*, such as *digbyano-Mossiae* and *Mme. Hye*, with broad, fimbriated lips are among the features of the gorgeous display. We have learnt to expect great things from Westonbirt, and there is no cause for disappointment. Every plant is a picture, and the whole of this extensive group does credit to Mr. Alexander, the ardent and successful cultivator.

Messrs. Charlesworth and Co., Hayward's Heath, have quite surpassed themselves in the magnificent group they are showing. *Miltonias* form a strong feature, and the rise in popularity of these flowers is due in a great measure to the efforts of this enterprising firm. *Odontiodas* are exceptionally fine, notably *Queen Mary* and *Enchantress*—two of the very best in the whole exhibition. A wide range of *Cattleya* hybrids, together with *Odontoglossums* and *Cymbidiums*, are prominent in this truly grand and in every way creditable display.

Messrs. Mansell and Hatcher, Rawdon, Yorks, have an extensive collection, in which most Orchids in season are represented. The *Cattleya* hybrids are worthy of special note, while the gems among *Miltonias*, *Odontoglossums* and *Odontiodas* arouse the admiration of all visitors.

Messrs. Stuart Low and Co. have a brilliant display, including *Cattleyas*, *Dendrobiums*, *Phalænopsids* and *Oncidiums* in all colours conceivable. The centre of this brilliant group is mainly occupied by the highly-attractive *Renanthera imschootiana*, of orange scarlet hue.

Messrs. J. and A. McBean of Cooksbridge are showing *Odontoglossum crispum* in remarkably good form, also *Cattleya* hybrids in exquisite colours, interspersed with a variety of *Cymbidiums* in long, arching sprays. About sixty plants of *Miltonias*, including the bright *Angusta*, are shown in this group.

Mr. Harry Dixon, Spencer Park Nursery, Wands-
worth Common, is showing Cattleyas, Odontoglossums and Miltonias in great variety. Among his best plants are Laho-Cattleya dominiana, a wonderful variety of L.-C. G. S. Ball and two albino Cattleyas, C. Skinneri alba and C. intermedia alba.

Messrs. J. Cypher and Sons, Cheltenham, are represented by a magnificent bank of such Orchids as *Miltoma vexillaria* in variety, *Phalanopsis rimstadiana*, *Laela Latona*, *Renanthera muschotiana* and *Dendrobium Thwaitesæ*. A little batch of the orange scarlet *Magdevalha grandiflora* is a showy feature of the bright and interesting display.

Messrs. Sander and Sons, St. Albans, have quite excelled themselves with their intensely interesting and well-staged group, in which *Odontoglossums*, choice Cattleyas, *Phalanopsids*, *Cymbidiums* and *Miltonias* are mingled one with the other. Among the gems of the collection are *Odontioda Laelia Sander*, *O. Roger Sander*, and *Brasso-Cattleya vilmoriniana Etna*. The choice collection of *Odontiodas* is the outstanding feature of this group.

From Sir Jeremiah Colman, Bart., Gatton Park, Surrey, comes an admirable display, in which fine spikes of *Odontoglossum crispum* Mary Colman and other varieties are mingled with the orange-tinted *Odontiodas*, such as *Bradshawia* and *Gatton Queen*. The effect is charming. A fine lot of *Miltonias* and Cattleyas are included in this group.

In Messrs. Hassall and Co.'s group from Southgate may be seen an admirable collection of *Miltonias*, *Odontoglossums* and a perfect specimen plant of the albino Cattleya *Skinneri alba*. *Laho-Cattleya Phœbe* is likewise well shown.

Mr. Sidney W. Flory, Twickenham, sends Cattleyas and *Odontoglossums* in great variety. *Trichopilia hennesiania*, with ivory white flowers, and *Cochlioda noetzhiana*, with vivid orange scarlet inflorescences, are two of the gems among the species shown.

Messrs. Armstrong and Brown, Tunbridge Wells, have an extensive and highly creditable group, comprising *Miltonias*, Cattleyas, *Cypripediums*, *Odontiodas* and *Phalanopsis*. *Cœlogyne dayana*, with pendulous chains of brownish flowers, is conspicuous in the background. *Odontioda Chanticleer* and *Miltonia vexillaria* G. D. Owen are two gems not to be overlooked.

Odontoglossum crispum and Cattleya *Mossie* in variety are the features of the group sent by Mr. C. F. Waters, Balcombe, Sussex. Large batches of *Miltonia vexillaria* are likewise included in this group.

SWEET PEAS.

The season of the year is not one at which it can reasonably be anticipated that Sweet Peas will be shown in that profusion and perfection which characterise them in the prime of summer. The flowers are from plants grown under glass; and from the fact that such protection is afforded it may be thought that the weather would be controlled, but such can never be the case. The present spring has undoubtedly been unpropitious, and it is therefore the more pleasing to be able to place on record the fact that many blooms of wonderful quality—quality spelling richness and purity of colour, excellence of substance, refinement of form, graceful placing on the stem and ample length of stalk—is to be seen in the Royal Hospital Grounds at Chelsea. Individual exhibitors are less numerous than might have been expected, but

the conspicuous absences were away under the compulsion of the weather, over which, happily, none of us has the least control. They were compelled to withdraw and their absence can only be described as a loss to the show, magnificent and varied as the display is as a whole.

Messrs. Dobbie and Co., Edinburgh, did not exhibit Sweet Peas from North of the Border, but from the metropolitan county of Essex. It is impossible adequately to praise them without being accused of gross exaggeration, so it shall suffice to say that they would have done credit to an exhibition in any centre of the British Isles in July. Quality and colour are emphasised by excellent arrangement. Along the back are plants 8 feet high in 6-inch pots, and in the foreground are superb bunches of many varieties. Of the new ones, personal taste will decide which is the most beautiful, and probably the most votes will go to Mrs. Mellick, of which the standard is rose and the wings a peculiar shade of blue. A renowned beauty is *Blue Phœbe*, with the finest thread of

P. Wright, Elfrida Pearson, Apple Blossom Spencer and Etta Dyke.

Essex is to the fore in a small group from Messrs. E. W. King and Co., Coggeshall, and the feature that most promptly strikes one is the quality of the varieties to which the prefix of Anglian is attached. There are *Crimson*, *Pink*, *Blue*, *Orange* and *Fairy*, not to mention *Royalty*, of which no mere man could reasonably be expected to describe the colour with even approximate correctness. Another beauty is Mrs. Reginald Hill, a warm lavender, while *Princess Mary* and *Electric* are both charming colours.

Messrs. Sutton and Sons, Reading, have a varied and delightful exhibit, and among the most beautiful features of which it is comprised is the collection of Sweet Peas—brilliant in colour, perfect in size, substance and form, and artistically displayed. Especially fine are *Avalanche*, *Royal Rose*, *Helen Grosvenor*, *Queen of Norway* and *Doris Usher*. Little, if at all, inferior are Mrs. Heslington, *Constance Oliver*, Mrs. W. J. Unwin,

A PORTION OF MESSRS. DOBBIE AND CO.'S SWEET PEA EXHIBIT.

colour round the white; while *King White* will probably reign for long. Among the other beauties are *Dobbie's Scarlet*, *Dobbie's Cream*, *Dobbie's Lavender* *George Herbert*, with *Ruby Palmer*, *Melba*, *Thomas Stevenson*, *Sunproof* *Crimson*, *Lady Miller*, *May Campbell*, Mrs. *Cuthbertson*, *Elfrida Pearson*, *Decorator*, *Brunette*, *Inspector*, *Marks Tey*, *Elsie Herbert*, *Rosabelle*, *New Marquis* and *Charles Foster*.

Robert Sydenham, Limited, Tenby Street, Birmingham, appear to have a rule in respect to their exhibits, of which the substance is that quantity must be subservient to quality. In the present instance the group of Sweet Peas is not extensive, but it has the merit of cheerfulness of colour and attractiveness of arrangement. The flowers are not conspicuous for size, neither are they carried on stems 2 feet or more in length, but they lose nothing on these scores. The most attractive varieties are *Hercules*, *Barbara*, *Edith Taylor*, *Princess Mary*, *R. F. Fulton*, *Maud Holmes*, *Walter*

Charles Foster and *Dragonfly*, which is peculiar in colour, the standard being very pale buff and the wings rose veined.

The only other exhibitor of Sweet Peas is Miss *Hemus*, Upton-on-Severn, who has a small exhibit.

HERBACEOUS & BULBOUS PLANTS.

By far the most beautiful, as it is also the most imposing and sumptuous of groups occurring under this head is that of Lilies arranged by Messrs. Wallace and Co. of Colchester, which will be found in the large tent. It is rich in Lilies and teems with the best of them, and, moreover, they will be found in admirable condition, despite the fact that they have been forced into bloom. The more worthy of these are *Hansoni* (orange), *Brown monadelphum* (*szovitzianum*), the rare *Trumpet Lily*, *L. myriophyllum*, and the inimitable *L. Kraemeri*. These latter are really admirable,

and should be seen by all. *Dalmaticum*, *Dal-hansonii* and *tenuifolium* Golden Glean are other good things to be found in this group, the accompaniments being *Astilbes*, *Irises*, *Gladioli* and the like.

Mr. Amos Perry has brought from Enfield a superb lot of things, and quite in the forefront will be found a rare grouping of Tree Pæonies, the finest of which is Louise Monchelet, a delightful pink of satiny hue. *Irises* of many sections are here, too, and such as *I. Korolkowii purpurea*, *I. vaga* and *I. tenax* will be noted at once. Two representatives of the *Reglio-cyclus* group are worth noting, *I. Hesperia* and *I. Hecate*. There are many other fine things to be seen.

Messrs. G. and A. Clark, Limited, Dover, display a fine lot of *Astilbe Davidii*, *Pyrethrums*, *Primulas*, *Irises*, *Verbascums*, *Eremuri* and other things of the showier class, good border plants withal.

In the group from Messrs. Jackman and Sons, Woking, there will be found many showy and useful subjects, *Delphiniums*, *Pæonies*, *Verbascums*, *Astilbes*, *Lilies* in variety, *Cypripediums* of sorts, the pretty *Iris cristata* and a fine lot of *Oxalis enneaphylla*.

The group from Mr. James Box, Lindfield, Sussex, will be found high up in the large tent, adjacent to a large collection of Ferns. It contains many excellent border and choice rock plants. The background of Bamboos is faced with *Anchusa Opal* and the rich blue of the *Delphinium Lamarum*, which is in capital form. Of choice *Primulas* there will be seen *bulleyana*, *Lissadell* hybrids, *beesiana* and *luteola*. *Incarvillea brevipes* and *I. grandiflora* are notably good, and should be noted by our readers. The white-flowered *Delphinium Progression*—a novelty withal—is also worth noting. *Anemone coronaria Rouge Ponceau* is of wondrous scarlet colour.

Messrs. James Veitch and Sons, Limited, Chelsea, are showing *Eremuri*, a fine lot of *Pentstemon Menziesii*, together with *Geum Mrs. Bradshaw*, *Pyrethrums*, *Irises*, *Lilies* and the new *Aster Purdomii* (see illustration page 260).

Messrs. Artindale and Son, Sheffield, have some excellent Tree Pæonies, early *Gladiolus*, *Megaseas* and a gay gathering of *Violas* in many varieties.

In the group from Mr. W. H. Rogers, Southampton, some fine *Primulas* will be found, also the brilliant scarlet-flowered *Ourisia coccinea* and the inimitable *Omphalodes Lucilæ*. *Corydalis nobilis* and the *Delphiniums* will not, of course, be passed by.

Messrs. Storrle and Storrle have one of their fine exhibits of *Anniculas* and *Polyanthuses*, the vigour and floriferousness of which will not fail to be admired. The strains of both, too, are excellent, and Scotland's air seems to imbue these things with new life.

Messrs. Whitelegg and Page, Chislehurst, have fine baskets of *Primula Vertchii*, *Habranthus pratensis*, *Aubrietias*, with a delightful lot of *Primula pulverulenta* and *P. cockburniana*.

The very fine groups—for there are two—of herbaceous *Phloxes* from Messrs. Gunn and Sons, Birmingham, are among the brightest features of the great tent. Messrs. Gunn are excellent cultivators of these plants, and they now show them very finely. *Elizabeth Campbell* (scarlet), *Duchess of Wellington* (mauve), *Le Mahdi*, *Ellen Willmott* (mauve), *Frau Antonie Buchner* (purest white) and *Countess of Ilchester* (orange scarlet) will be found among the most distinct. *Viola Moseley*

Perfection is a great thing in yellow-flowered varieties.

Quite in the opening of the large tent from the Embankment side will be found the sumptuous grouping of *Delphiniums*, Tree Pæonies, *Pyrethrums*, *Gaillardias* and yellow *Lupines* from Messrs. Kelway, Langport. We have frequently observed that it is better to display a few plants in good condition than to show a whole army of things, meaningless, dowdy in colour, and of no significance. Messrs. Kelway are doing the former, the result being a very fine display.

Mr. Frank Lilley, Guernsey, has one of those attractive groups which at this early season of the year only this favoured island can show. *Sparaxis*, *Irises*, *Camassias* and other things will be found.

Messrs. Reamsbottom and Co., Geashill, King's County, have one of their fine displays of *St. Brigid Anemones*, and the great variety of colour, cheapness and easiness of culture should tempt thousands to grow these showy flowers.

Mr. W. Lawrenson, Yarm-on-Tees, is staging on a table space in the big tent a variety of hybrid *Primulas*; but from either the day, the sunlessness or covering canvas, we failed to see any advance upon well-known kinds.

From Dr. Macwatt, Morelands, Duns, N.B., may be seen basket groups of many *Primulas*, the majority interesting rather to the botanist than to the gardener. Duns, we had hoped, would follow Edinburgh's lead and demonstrate to residents in southern gardens how much elevation, northerliness and coolness are to these plants. Dr. Macwatt's exhibits do not demonstrate these things. The inimitable *P. glutinosa* is better from Mr. Farrer; the free-flowering *P. Veitchii* is superior everywhere. Hence we enquire, after all, is it cultural skill, and not position or locality?

Mr. G. Underwood, Leicester, also shows *Violas*.

The Wargrave Plant Farm, Twyford, have a small rockery exhibit under canvas, and at least two things should attract our readers thereto. They are *Cypripedium montanum* and *Æthionemaschistosum*, a pretty, pink-flowered plant for rockwork or alpine wall. *Ourisia coccinea* and *Gentiana verna* will also be found very charming.

Baker's, Wolverhampton, will be found to have a rather extensive grouping of *Primulas*, *Meconopsis cambrica fl.-pl.*, *Cypripedium spectabile* and *Incarvillea grandiflora*. The plants will be seen in groups suggestive of what may be done in the garden.

VIOLAS AND PANSIES.

A very bright and attractive display of *Violas* and *Violettas* is shown by Mr. Howard H. Crane, Woodview, Highgate, N., embracing many of the leading bedding sorts, to which this grower especially devotes his attention. Among other good *Violas* are *May*, *Luigi*, *Royal Sovereign*, *Mrs. E. A. Cade*, *Constance*, *Leonora* and *Mrs. B. Eric Smith* (all noteworthy yellow sorts), *Admiral of the Blue* and *Royal Blue* (rich blue varieties), and others of various colours are *Nellie Chapman*, *Lark*, *Nancy* (velvety), *Ruth Wilks*, *Nellie Harston*, *C. B. Murray*, *Mrs. Chichester*, *Swan* and *Maggie Mott*. Pretty *Violettas* are *Eileen*, *Chloris*, *Yellowhammer*, *Butterfly*, *Cynthia* and *Rock Yellow*.

Messrs. Dobbie and Co., Edinburgh, have a number of *Pansies* and *Violas* growing in pans, illustrating their true character in this way. Good sorts of *Violas* are *Jubilee*, *Lord Shaw*, *Royal Sovereign*, *Snowflake*, *King Cup* and *Blue Cloud*.

The fancy *Pansies* are fine, some being very striking. Noteworthy varieties are *Unicorn*, *Sunburst*, *Emma Bateman*, *Mrs. C. Kay*, *John Picken* and *Attraction*. *Viola Moseley Perfection* is shown as growing plants lifted and placed in baskets. This is a wonderful yellow *Viola*. Other sorts are *Admiral of the Blue* and *Agnes Kay*. There is also a beautiful lot of *Viola cornuta purpurea* and *V. gracilis*. This last series is exhibited by Messrs. Gunn and Sons, Olton, Warwickshire.

John Forbes, Hawick, Limited, in addition to several other things, has a capital display of *Violas* and *Pansies*. Exhibition and bedding *Violas* are represented by the following, among others; *Campbell Bannerman*, *Mrs. D. Davidson*, *W. H. Woodgate*, *Mary Burnie*, *William Daniels*, *John Forbes*, *Glencoe*, *James Pilling*, *Blanche* and *Purity*.

Mr. George Underwood, Leicester, has a small group of the more popular *Violas*, showing three blooms each of a number of good sorts. *Walter Welsh* (rich yellow), *John Smellie*, *Dusky Monarch*, *Gladys Finlay*, *A. S. Frater*, *Nettie Macfadyen*, *Admiral of the Blues* and *Henry Hamilton* are conspicuous. *Viola cornuta purpurea* is shown in glass vases on three semi-circular arrangements in front of the exhibit.

A new exhibitor in the person of Mr. W. R. Trauner, Alma Nurseries, Cottingham, Hull, stages *Violas* in sprays with appropriate foliage. Here are to be seen well-known sorts in fresh condition, such as *G. C. Murray*, *Mrs. Chichester*, *Moseley Perfection*, *Maggie Mott*, *White Swan* and *Archie Grant*; also *Viola cornuta purpurea*, *V. c. alba* and *V. c.* variety *Fragrance Queen*.

Mr. G. W. Miller, Wisbech, stages with his hardy flowers a number of *Violas*; *Royal Blue*, *Moseley Perfection*, *Seagull* and *Bridal Morn* are their names. He has also *Viola cornuta* and its varieties, which are well shown.

Messrs. Carter Page and Co., London Wall, E.C., in addition to *Dahlias* and other things, have an interesting collection of *Violas* in fresh and clean condition, set up in pans of sand. *Mrs. C. F. Gordon*, *Maggie Mott*, *Kathleen Gordon*, *Mrs. Airdrie*, *Kitty Bell*, *Moseley Perfection*, *Bronze Kintore*, *Swan* and *Archie Grant* are some of the more distinct kinds.

Messrs. W. Artindale and Son, Sheffield, Yorks, have edged their group of hardy flowers with a number of *Violas* planted out in *Coccoloba* fibre in irregular colonies. The more striking sorts are *Margaret Wood*, *J. H. Watson*, *Kathleen*, *Minnie J. Ollar*, *Admiral of the Blue*, *A. S. Frater*, *Countess of Eglinton* and *Gladys Finlay*, and with *Viola cornuta purpurea* makes a nice finish.

Messrs. Gunn and Sons have a pretty circular group of *Viola cornuta purpurea*, set up in tubes in a cut state, making a mass, and contrasting with several *Saxifrages* in the centre of the group. This is a very simple but charming little display. Masses of *Violas* form an irregular and pretty edging to Messrs. Ware's group of hardy flowers. Here are massed in colours such sorts as *Royal Sovereign*, *Maggie Mott*, a purple, white, and a blotched blue variety.

Pans of *Violas* form a ring round two groups of plants shown by Messrs. R. H. Bath, Limited, Wisbech. In this way the plants are effectively shown, the public by these means obtaining a good idea of the habit of the respective varieties. Among other good things are *True Blue*, *Seagull*, *Molly Pope*, *Primrose Dame*, *Councillor Waters*, *Ethel Baxter*, *Royal Blue* and *Any Barr*. There are also several pans of fancy *Pansies*.

CARNATIONS AND PINKS.

Truly magnificent aptly describes the wonderful exhibit of Carnations set up by Mr. C. Engelmann, Saffron Walden, Essex. Tall pillars, artistically arranged with blooms of Lady Northcliffe, Rosa, Sunstar, White Enchantress and Elektra occupy the centre of the group, and out of the groundwork of smaller vases there rise stately vases of such sorts as the rich crimson Carola, White Mrs. Lawson, Beacon, Triumph, Benora, White Wonder, My Rose and Pioneer, among others. Edged with well-grown Ferns the effect is distinctly beautiful, and does this exhibitor great credit.

A circular group on a raised platform is occupied with a dainty group of Carnations by Messrs. Stuart Low and Co., Bush Hill Park, Middlesex. Malmaison, Mrs. C. F. Raphael, Princess of Wales, Princess Juliana, Churchwarden, Marmion, Duchess of Westminster and Gemma were all good. Among the Perpetual-flowering varieties that are noteworthy are British Triumph, Baronesse de Brienne, Empire Day, Scarlet Glow, Farmount, Cinnabar and White Wonder. Surmounted with Palms and edged with Ferns and moss the effect is pretty.

Near to the Embankment entrance is a triangular table group of Carnations, set up in quaint and artistic vases and charming baskets by Mr. A. F. Dutton, Iver, Bucks. The blooms in this group are remarkable for their clear, bright and striking colours; in fact, there is nothing like it in the exhibition. Britannia, Scarlet Glow, Triumph and Harlowarden are blooms of wonderful colours. Beautiful, too, are the pink tones of colour as represented by May Day, Mrs. A. F. Dutton, Rose Pink Enchantress, Enchantress, Winsor and others. Niagara and White Enchantress are superb white kinds. Mention should also be made of Mikado, the deep mauve of a unique tone of colour.

Perpetual-flowering Pinks are well shown by Mr. C. H. Herbert, Acocks Green, Birmingham, and are very welcome at this early period. Progress, Sunset, Delicata, Cottage Maid and Eclipse (a new salmon pink coloured sort, of a size equal to a Malmaison Carnation) are a pretty feature of this great show. Edged with Ferns and other foliage plants, this made a charming group.

A few tall vases of Carnations comprise part of the group set up by Mr. S. Mortimer, Rowledge, Farnham, Surrey, embracing several of the popular sorts that now find favour, including Victory, Triumph and Alma Ward.

Mr. Charles Blick, The Warren Nurseries, Hayes, Kent, so long associated with the late Mr. Martin Smith as his gardener, exhibits a very pretty little group of well-grown Carnations. Beacon (glorious), Enchantress, Salome, Empire Day, Scarlet Glow, Cecilia, R. F. Felton, White Wonder, Mikado, Winsor, Lady Alington, Scarlet Beauty, Mrs. C. Ward and King George are all well done.

An interesting collection of Carnations calls for note as shown by Mr. J. D. Webster, Chichester. Some of the blooms are remarkably handsome, such as Cecilia, Lady Coventry, H. J. Jones, Triumph, R. F. Felton, Lady Meyer, Rose Pink Enchantress, Carola and others.

Another beautiful representation of Carnations is that seen in the group set up by Messrs. Young and Co., Hatherley, Cheltenham. The roses, both large and small, are charmingly disposed on a groundwork of moss and foliage plants, and the effect is distinct and very pleasing. In the centre is a high stand of Cecilia, and four others, equidistant, of Duchess of Devonshire, Hon. Lady Neeld (two) and White Enchantress. Other small vases worthy of note are Edith Waters, Regma,

Britannia, Mrs. Raphael, Winsor, Mikado and Scarlet Glow.

Associated with Azaleas, Mr. Charles Turner, Slough, has a number of Carnations in pots, such as Nautilus, Nell Gwynne, Lady Middleton, Princess of Wales and Thora.

A large circular group is set up by Messrs. William Cuthbush and Sons, Highgate, N., and Barnet, Herts. This is another of the splendid efforts at this show, and the effect is truly artistic. Surmounted by a Palm in the centre of the group are Carnations, arranged in a receptacle high up above a mound of Lady Coventry in the pink of condition; well-elevated stands of Mrs. Lucy Mackinnon, Marmion, R. F. Felton, Mrs. C. F. Raphael, White Wonder and others; and in a charmingly undulating groundwork of Ferns and numerous other Carnations a handsome group is brought into effect.

A group of an undulating character embracing Statice and Malmaison Carnations, set up by Mr. Leopold de Rothschild, Gunnersbury, W. (gardener, Mr. J. Hudson), is a fine effort. The Carnations are of the Malmaison type, and the plants are well grown and the flowers all that could be desired. Princess of Wales and Blush Malmaison are the two

TREES AND SHRUBS.

Hardy Azaleas as shown by Messrs. R. and G. Cuthbush, Southgate, N., are always a great feature at the spring show of this society, and the display made by this firm this year is no exception to this excellent rule. Two really magnificent groups aptly describes this display of free-flowering plants. The colours are gorgeous, and the quality of the flowers all that could be desired. Mollis, Leon Vignes, J. C. Van Thol, Consul Ceresole, J. C. Van Thol Imperial, Chevalier de Reali and Baron Edmund de Rothschild are all noteworthy. Varieties of mollis x sinensis worthy of special mention are T. J. Seidel, Nicholas Beets, Ellen Cuthbert, Aureus and Clara Butt. Varieties of rustica fl-pl. that call for notice are Corneille, Phebe, Il Tasso and Aida. Edged with Ferns, the irregular grouping of the hardy Azaleas makes this exhibit a great feature of the show.

Mr. Charles Turner, Slough, groups plants and cut sprays of Lilacs in charming variety. Some of the plants need a little more time before they can be regarded as in proper condition. Volcan, Dr. Lindley, Charles X., Marie Légraye, Mme. F. Morel and Negro are good single-flowered sorts.

A CORNER OF MESSRS. SUTTON AND SONS' EXHIBIT, WHICH WAS COMPOSED ENTIRELY OF PLANTS RAISED FROM SEEDS.

varieties exhibited. Rarely are these two Carnations so well shown, and there is little doubt they will be noted by many who desire to excel in the cultivation of this type of the flower.

An attractive exhibit of Carnations is that pleasingly disposed by Mr. Bertie E. Bell, Cashel Nursery, Guernsey. Unique stands, stately vases and long glasses are artistically arranged with most of the leading varieties in fresh and clean condition. Among others to be seen in this table group are Winsor, Enchantress, Coronation, May Day, Mikado, Scarlet Glow, Judith, White Enchantress, Mrs. C. W. Ward and Marmion.

A pretty table group of Carnations is set up by Mr. H. Burnett, Guernsey. The flowers in this collection are very bright and of good quality throughout. Marmion, Mrs. C. F. Raphael, R. F. Felton, Carola, Benora, Beacon, White Wonder, Calypso, Mikado, Scarlet Glow and Mrs. Tatton are a few of the good things to be seen in this attractive group.

Doubles are represented by Arthur W. Paul, Mark Micheli, Mme. Casimir-Perier, President Carnot, Mme. Lemoine, Belle de Nancy and others.

Japanese pigmy trees are well shown by Messrs. Barr and Sons, Covent Garden, London, W.C. Seldom have these quaint and curious examples of dwarf trees of ancient origin been represented in better condition, and their staging in a square group so that each individual specimen can be seen is a great advantage.

Messrs. W. Cuthbush and Son, Highgate and Barnet, staged a miscellaneous group of flowering plants and other subjects. Rhododendron Pink Pearl, hardy Azaleas, Marguerite Pink Perfection, Hydrangea Mariess, H. Monneur Ghys and Araucaria Silver Star are among the interesting things in this group.

Lilacs are shown by Messrs. W. and J. Brown, Stamford, near to the Embankment entrance. Although the plants are not large, there is a beautiful variety of both double and single kinds. Good

double sorts are Mme. Lamome Creanon, J. Guillot, Alphonse Lavallee and Leon Simon. Singles are interesting, such as Marie Legraye, Souvenir de Louis Spathe, Geant des Batailles and Mme. Françoise Morel.

New Chinese trees and shrubs are exhibited by Messrs. James Veitch and Sons, Limited, Chelsea, and are a constant source of attraction to many. Some of the more interesting plants are Cotoneaster Harroviana, Pyrus Folgeri, Stranvasia undulata, Sturtia monogyna, Viburnum rhytidophyllum, Vitis armata, Viburnum Henryi, V. Davidii and Cotoneaster rugosa. Altogether a most interesting collection.

From Messrs. James Veitch and Sons, Limited, there is also a beautiful group of miscellaneous flowering trees and shrubs. Rhododendrons, Wistarias, Loniceras, hardy Azaleas, Clematises, Philadelphuses, Hydrangeas, Cytisuses and Rosa Hugonis are all very charming. Rhododendrons Mirabile, White Pearl, Pink Pearl and other varieties, together with the above-mentioned subjects, form a mass of flowers that is the centre of attraction to many.

Messrs. Stuart Low and Co., Enfield, Middlesex, have a mixed group of hardy and tender plants, in which Hydrangea The Bottle Brush Tree (*Metrosideros floribunda*), *Leptospermum bullatum* and *Acacia pulchella* are conspicuous.

Hardy Rhododendrons as exhibited by Messrs. John Waterer and Sons, Limited, Bagshot, Surrey, are a very fine feature indeed. The plants are in pots and are well grouped, and the flowers are superb. Some of the better varieties are Alice, Mrs. Fritton, Comet Waterer, Pink Pearl, Prometheus, Brilliant, Martin Hope Sutton, Marchioness of Lansdowne and Strategist. A few Acers dotted about here and there enhance the beauty of the display.

Wistarias in variety, growing in quaint and curious receptacles, are exhibited in interesting fashion by Messrs. Pipers, Bayswater, London, W. Rarely does the British public have an opportunity of seeing anything so novel, and some of the plants are flowering most profusely.

Mr. R. C. Notcutt, Woodbridge, has an interesting assortment of flowering and other shrubs, all combining to make a pretty exhibit. *Cytisus andreaeanus*, *C. albus*, *C. Daisy Hill*, *C. andreaeanus prostratus*, *Kalmia latifolia*, Lilaes, *Fabiana imbricata*, Acers and a host of pretty things are noteworthy.

Messrs. William Paul and Son, Waltham Cross, Herts, have a square, compact group at the side of the big tent embracing flowering trees and shrubs in variety. Rhododendron Pink Pearl, R. Lord Palmerston, hardy Azaleas, *Genista hispanica*, *Cytisus albus*, Honeysuckles, Clematises and numerous other subjects made a useful and interesting exhibit.

Rhododendrons in small baskets are represented in great variety in a group set up by Messrs. Fletcher Brothers, Chertsey, Surrey. William Austin, Helen Shiffner, Limbatum and Profusion stand out from the rest.

Clematises from Messrs. George Jackman and Son, Woking, Surrey, are always eagerly sought after,

and a charming group will reward the seeker at this show. Quality of bloom is very noticeable, and many of the plants will be better a week later. The group, however, left nothing to be desired; interspersed with Palms and silver Acers the effect was distinctly pretty. A few good sorts are Lady Caroline Nevill, *Jackmann rubrum*, Fairy Queen, Imperatrice Eugéne, Nellie Moser, Ville de Lyon and Mrs. George Jackman. This group is edged with Maidenhair Fern, and is a welcome relief to the gorgeous colouring elsewhere. Miscellaneous flowering shrubs and other plants are also well shown in another group by Messrs. George Jackman and Son. This is a very bright and attractive lot of plants, and all are well grown and freely flowered. Superb is *Kalmia latifolia*, and other good things are: *Escallonia laugleyensis*, *Cytisus scop. us andreaeanus*, *Andromeda speciosa*, *Ledum latifolium* and *Lila Mme. F. Morel*.

HYDRANGEA SARGENTII, A NEW SPECIES FROM NORTHERN CHINA, SHOWN BY MESSRS. J. VEITCH AND SONS.

Hardy ornamental shrubs in the form of an outdoor group of a most varied collection of Acers was a praiseworthy effort on the part of Messrs. John Waterer and Sons, Limited, Bagshot, Surrey. Half-a-dozen of the best sorts are *Acer palmatum* var. *laciniatum atropurpureum*, *A. p.* var. *dissectum palma-indum*, *A. p.* var. *corallinum* (very fine), *A. p.* var. *dissectum florescens*, *A. japonicum* var. *aureum* and *A. p.* var. *sanguineum*.

Clipped Box trees are extensively shown by Messrs. Carlton-White, 53, New Bond Street, W. In this group there are represented such subjects as Teddy Bears, dogs, peacocks, ducks, spirals, vases and a host of other designs too numerous to mention. This is a very large group.

Mr. L. R. Russell stages a most attractive group of Tree Vines in beautiful variety, and most of them in splendid growth and good condition. A few

kinds worthy of special notice are Sheen Silver (used as a fronting to the group), Gold Cloud, *flavescens*, *amurensis*, *fructo-lutea*, *palmata aurea* and *marginata alba*. There are some handsome specimens of *dentata variegata*.

A very large and representative group of clipped Box and Yew is set up by Messrs. William Cutbush and Sons, Highgate and Barnet. This firm is famous for its topiary work, and the present collection well merits a visit. Here are to be seen, in good form and condition, representations of ships, baskets, vases, anchors, tables, birds of every description, dogs and spirals. It is pleasant to view this outdoor group after the plethora of flowers indoors.

Comprehensive aptly describes the large outdoor group of Mr. L. R. Russell, Richmond, Surrey. In this charming group are to be seen hardy Azaleas in variety, *Ceanothus veitchianus*, *Olearia Gunnii*, *Cytisus* in variety and a pleasing assortment of Vines. *Vitis henryana* is in very handsome form just now. Aucubas, *Hypericum moserianum tricolor*, *Cupressus erecta aurea* and a number of very interesting plants are admired by the many visitors.

A series of outdoor groups of trees and shrubs, arranged in the form of beds, is a useful and practical way of showing the value of the subjects planted therein. Hardy Azaleas are planted along in one bed, Acers in another, Rhododendrons, Lilies, Viburnums, Weigelas, Cytisuses and many other pretty subjects in another, all combined to transform the grounds into a veritable pleasure ground or garden. This is a splendid conception of what visitors may in the future hope to see at these shows, and Messrs. Cheal are to be congratulated on this fine effort.

Clipped trees, as shown by Messrs. John Piper and Sons, Bayswater, London, W., made a fine display. In this collection there are many very handsome matured specimens, representing a host of subjects. Peacocks, spirals, double arches, a man sitting on a garden seat and several unique designs seemed to appeal to many.

Beds of hardy Azaleas and Rhododendrons and other hardy flowering shrubs are pleasingly set out with paved walks between them, and garden seats arranged in suitable positions. The whole display is hedged in with closely-planted Yews, and the conception of this

idea reflects much credit on Mr. R. C. Notcutt, Woodbridge, the exhibitor. The beds are raised very considerably, heightening the effect by these means.

Messrs. James Carter and Co. also have a beautiful outdoor garden, the beds of which are planted with hardy Azaleas, Viburnums, Acers and coniferous subjects, all combining, with the wall garden, to make a really pretty scene.

Messrs. Paul and Son, Cheshunt, stage a number of novelties in hardy Azaleas, some of which are remarkable for their novelty of colouring. Edith J. Keysell, High Beech Orange, Glory of Cheshunt, Moore and Milton are a few of the more striking sorts.

A very large and comprehensive group of Acers was exhibited by Messrs. W. Fromow and Sons, Chiswick, W. There seems to be an almost endless

variety, and the arrangement of the plants and their character prove at once their decorative worth in the garden. *Acer palmatum corallinum*, *A. japonicum anreum* and *A. dissectum atropurpureum* are conspicuously good.

Standard mop-headed Bays and a nice assorted lot of those of pyramidal form are exhibited by Messrs. John Piper and Sons, London and Barnes, Surrey.

Dwarf Japanese trees are shown by Messrs Liberty and Co., London and Paris, together with a number of accessories for a Japanese garden. A fine specimen of a dwarf tree, some two hundred years old, occupies a prominent position in this collection.

TULIPS.

Tulips are magnificently shown this year. Considering the inclement season, it is wonderful how such fresh flowers as are to be seen, say, in Messrs. Sutton's group, have survived in the condition in which they are presented at this show. The effect of the friendly covering of a grass shade during the latter part of their growth does wonders for Tulips, and there is no secret in the fact that the glorious examples of Mrs. Farncombe Sanders, Inglescombe Yellow, Mrs. Moon and Inglescombe Pink on Messrs. Dobbie's stand owe everything to this. It is unfortunate that for some reason or another the firm has not entered their Tulip group for award.

The large and varied group of Messrs. A. Dickson and Sons of Belfast is a delightful bit of arrangement, although the bottom row of vases look as if they had been disturbed before the grouping was quite finished. They include a very varied assortment of the different types and, together with that of Messrs. Barr and Sons, it has probably more instructive interest than any other.

Messrs. R. H. Bath of Wisbech has a collection arranged almost entirely on the ground and broken with five pillars of Rambler Roses. It makes a bright bit of colour, but somehow the grouping looks a little too mixed up to be very striking and it does not do itself justice in consequence. The few blooms of the famous Tulipe Noire surrounded by the beautiful pale yellow Leghorn Bonnet look well.

Mr. C. W. Needham has, what is very seldom seen, a good selection of the strictly florist types, such as Sir Joseph Paxton, Eos and Trip to Stockport. It is a thousand pities that the blooms are not set out to more advantage, as the public is so seldom treated to a display of these old-world beauties.

The Tulip hill of Messrs. J. Jefferies and Son of Cirencester is the most decided novelty in the way of arrangement in the whole exhibition. It has many things that could be said in its favour, but space forbids us to say more. This firm has immensely improved upon its show at the "International" last year, and it had only had larger blooms, it would, we think, have qualified for a higher award than that which it received. Bronze Queen (or Clio, to give it its old name) and the never-to-be-surpassed *gesneriana major* were both good. So, too, were the vases of the grand old double "Blue Flag." Messrs. James Veitch and Messrs. Hogg and Robertson have two of the brightest displays of the day. In both cases the blooms are large and clean. The large masses of one colour affected by the former do show a variety to great advantage and must inspire those hesitating

about a purchase more than, say, an isolated vase. The latter firm stage more variety, and among them are to be noted Plurot (pale pink), Erguste, Hammer Hales and Rossetta (rose slightly edged yellow).

Mr. C. Bourne has a small but well-grown and well-staged collection. Solfatare, Scarlet Emperor and Zulu were much above the usual average.

Messrs. Cartwright and Goodwin and the Wargrave Plant Farm both have small and interesting exhibits, and both have flowers in fresh condition. They will probably be finer on the last day, when they have grown, than on the first.

Dealing with the general arrangements of the show, we would like to be able to see the different groups in a little more comfortable manner when the general public come in. The gangways are much too narrow. Tulips do want to be seen at a little distance.

FRUIT.

It is clear that the exhibits in the fruit section have been prejudiced by the weather; not that those at Chelsea are inferior, except perhaps in colour, but

the beautiful collection of Strawberries. The fruits are large, firm and the colour in most instances nothing short of wonderful. The varieties include King George, The Queen, The Earl, International and Maincrop. This firm also shows Loganberries, Laxtonberries, standard Gooseberries and Currants, as well as Peaches and Nectarines. Out of doors Messrs. Laxton have a very fine exhibit of trees trained in various forms.

Apples of the summer, autumn, winter and spring are equally represented in the collection shown by Messrs. G. Bunyard and Co., Limited, Royal Nurseries, Maidstone. They are a splendid object-lesson of the manner in which Apples may be kept when the conditions and circumstances are favourable. The varieties include King of Tompkins' County, Calville Malingre, Belle de Pontoise, Sturmer Pippin, King of Pippins, Cox's Orange Pippin, Alfriston, Hornmead's Pearmain, Bramley's Seedling, Belle de Boskoop, Newton Wonder, Diamond Jubilee, Claygate Pearmain, Lord Derby, Ribston Pippin, Hambling's Winter Queen and Gascoyne's Scarlet Seedling. There are also some fine fruits of Uvedale's St. Germain Pear.

PART OF THE COLLECTION OF MAY-FLOWERING TULIPS SHOWN BY MESSRS. A. DICKSON AND SONS OF NEWTOWNARDS.

they are not as numerous as might be expected and desired at a gathering so representative of British horticulture. With one exception the displays were of trees in pots or of trained specimens lifted from the open ground.

The King's Acre Nurseries, Limited, Hereford, have a varied group of plants fruiting in pots. Among the notable features are James Grieve, Lady Sudeley, Red Astrachan and Irish Peach Apples; Souvenir du Congrès, Marguerite Marillat and Conference Pears; British Oak, Progress, Lady Leicester, May Duke, Whinham's Industry, White Eagle, Dr. Wooley and Clayton Gooseberries; Cardinal and Early Rivers' Nectarines; Duke of York Peach; Negro Largo, White Ischia, Golden Brunswick, Pingo de Mel and Black Bourjasotte Figs; and Early Prolific, July Green Gage and Blue Rock Plums.

It is surely superfluous to say that the outstanding feature of Messrs. Laxton Brothers' groups is

Oranges, Lemons and Citrons from Messrs. T. Rivers and Sons, Sawbridgeworth, are interesting examples of excellent culture, and suggest that these valuable fruits might well be far more extensively grown in our gardens. The same firm has also a separate group of Peaches Peregrine and Kestrel; Plums Stint, Early Prolific, Early Rivers and Blue Rock; Cherries May Duke, Elton, Frogmore Bigarreau and Knigt's Early Black; and Nectarines Early Rivers and Cardinal. Needless to say the plants were clean and splendidly fruited.

In the grounds, surrounded by gorgeous flowers and charming rock gardens, Messrs. James Veitch and Sons, Limited, Royal Exotic Nursery, Chelsea, have a group of fruit trees trained in many forms, and they gain interest from their neighbours. The trees are perfect examples of how training should be done, and they illustrate how fine crops can be produced on a very small space.

VEGETABLES.

A collection of vegetables of superb quality comes from the Hon. Vicary Gibbs, Aldenham House, Aldenham, Herts. (gardener, Mr. E. Beckett). The collection, which is staged in a masterly way, contains Peas Early Giant, Quite Content and Selected Duke of Albany (all with well-filled pods and in perfect condition), Climbing French Bean Princess of Wales, Dwarf Bean Canadian Wonder and Broad Bean Mammoth Longpod. Of the Cucumbers staged, Sutton's Matchless is doubtless the best, and other vegetables include Turnips White Gem and Early White Milan, Tomatoes Peachblow and Sutton's Ar, Kohl Rabi, Vegetable Marrows, Cauliflower Magnum Bonum, Beetroot Sutton's Globe, Mushrooms, Potato King Edward VII. and Duke of York, Globe Artichokes, Egg Plants (purple and white) and Radishes. It is an admirable collection, worthy of the highest praise.

From the Thatcham Fruit and Flower Farm, Newbury, comes a creditable collection of vegetables, including Cauliflowers First Crop and Snowball, Tomatoes Early Market and Holmes' Supreme, Potatoes Duke of York and May Queen, Cucumber Covent Garden Favourite, Pea Gradus, Radishes, Lettuces, Beans, Carrots, Spinach and Vegetable Marrows. This exhibit was arranged by the ladies from the Horticultural Training School at the Thatcham Fruit and Flower Farm.

Two new Cucumbers are being shown by Mr. S. Mortimer, Rowledge, Farnham, Surrey. The varieties are Continuity and May Queen. Both varieties were shown in perfect condition and uniform in size.

Entering the main entrance from the Embankment, one of the first exhibits to be observed is that of Messrs. James Carter and Co., in the form of a choice collection of vegetables arranged on a neat and effective white stand. The vegetables, all of which are grown from Carter's Tested Seeds, include Cauliflowers Forerunner and Defiance Forcing, Broccoli Spring White, Peas Early Morn and Early Duke, Dwarf Bean Improved Longsword, Broad Bean Seville Giant Longpod, Cucumbers Carter's Ideal and Frame, Seakale, Beet, Tomatoes, early Carrots, Lettuce, Kohl Rabi, Radishes, Potatoes and Marrows. This exhibit is of very high quality.

Messrs. Sutton and Sons, Reading, have arranged an exhibit of tempting early vegetables and delicate salad. The produce of the firm's well-known varieties include Dwarf French Bean Superlative; Peas Duke of Albany, Green Gem and Early Giant; Cucumber Telegraph, Tomatoes Early Market, Winter Beauty, Eclipse and Princess of Wales; Asparagus Reading Giant and Perfection, Potatoes, Turnips and Carrots. This is a first-rate collection.

Mr. Theo. E. Dawes, Syderstone Nurseries, Norfolk, is showing a fine collection of Rhubarb, with sticks of Dawes' Challenge well over three feet in length.

AWARDS.

FLORAL COMMITTEE'S AWARDS.

First-class Certificates.—*Nephrolepis exaltata* Willmottæ, from Messrs. May; *Cupressus lawsoniana* Fletcheri, from Mr. Fletcher; and *Meconopsis Delavayi*, from the Edinburgh Botanic Gardens.

Botanical Certificate.—*Olearia Chathamica*, from the Rev. A. T. Boscawen.

Awards of Merit.—*Campanula Stevensii* nana, from Mr. R. Prichard; *Pentstemon Davidsonii*,

from Mr. Elliott; *Auricula* William Smith, from Mr. Douglas; *Calceolaria* Clarefield Gem, from Mrs. Litkie; *Rose* Nancy Perkins, from Messrs. Perkins; *Rose* Irish Fireflame and *Rose* Mrs. Campbell Hall, from Messrs. Alex. Dickson; *Saxitraga* Grandfield, from Sir Everard Hambro; *Begonia* Lena, from Messrs. Blackmore and Langdon; *Roscoea cauthioides*, from Bees, Limited; *Rose* White Tausendschön, from Mr. W. Paul; *Sarracenia Brucii*, from Mr. A. J. A. Bruce; *Aster Falconeri*, from Messrs. Barr and Sons; *Cytisus andreana* prostrata, from Mr. L. R. Russell; *Styrax Wilsoni*, from Miss Willmott, V.M.H.; and *Lonicera tragophylla*, from Messrs. J. Veitch and Sons.

ORCHID COMMITTEE'S AWARDS.

First-class Certificates.—*Cattleya* Empress Frederick alba, from Messrs. Marshall and Hatcher, Rawdon, Leeds; *Odontioda* Chanticleer Orchidhurst variety, from Messrs. Armstrong and Brown, Tunbridge Wells; *Lælio-Cattleya Britannia* Westonbirt var., from Lieutenant-Colonel Sir George

AN EFFECTIVE GROUP OF TULIPS ARRANGED BY MESSRS. R. H. BATH, LIMITED, ON THE FLOOR.

Holford, Tetbury, Gloucestershire; *Lælio-Cattleya* Sylvia, Princess Victoria Louise and *Miltonia* Charlesworthia, from Messrs. Charlesworth and Co., Hayward's Heath; *Lælio-Cattleya* Frederick Boyle Gatton variety and *Odontoglossum* Queen of Gatton, from Sir Jeremiah Colman, Reigate; and *Odontoglossum* Othmarschem, from Baron Bruno Schröder, Englefield Green.

Awards of Merit.—*Odontoglossum* eximium Armstrongæ, *Brasso-Cattleya* Excelsior and *Lælio-Cattleya* Aphrodite splendens, from Messrs. Armstrong and Brown, Tunbridge Wells; *Oncidium* McBeanianum, *Cattleya Mendelii* May Queen, *Odontioda* Charlesworthii Perfection, and *Cymbidium* gottianum superbum, from Messrs. J. and A. A. McBean, Cooksbridge; *Lælio-Cattleya* Ganymede Holford variety and *Odontoglossum* Illustrissimum Westonbirt variety, from Lieutenant-Colonel Sir G. Holford, Tetbury, Gloucestershire; *Odontioda* chelseaensis variety St. Fuscien, from M. Graire, Amiens, France; *Odontoglossum* Georgius Rex, from Messrs. Charlesworth, Hayward's Heath; *Brasso-Cattleya* vilmoriana var. Etna, *Odontonia* Lælia Sander and *Oncidioda* Cooksonæ var. illustris, from Messrs. Sander and Sons, St. Albans.

Cultural Commendations.—*Sobralia macrantha* alba, from J. Gurney Fowler, Esq., South Woodford; *Miltonia* vexillaria virginalis, *Miltonia* vexillaria Snowflake and *Cattleya* Mossie Mahomet, from Lieutenant-Colonel Sir G. Holford, Tetbury, Gloucestershire.

The Farrer Cup for the best six new or rare dwarf rock plants was awarded to Messrs. Bees, Liverpool, and the Davidson Cup for the best *Cattleya*, not a hybrid, to Messrs. Charlesworth, Hayward's Heath, for *Cattleya percivaliana* Mary Regina.

The other cups and medals awarded were not known at the time of going to press.

SUNDRIES.

OUTSIDE.

A specially interesting exhibit of boilers is being shown by Messrs. C. P. Kinnell and Co., Limited, 65, Southwark Street, E.C., including models of the Anglian independent sectional of new and improved form. The Rochford and Bisson

are also suitable types for large growers, and amateurs' needs are catered for with the Horse-shoe and Charm patterns.

Messrs. Skinner, Board and Co., Exmoor Street, Bristol, have specimens of their noted wire tension span-roofed glass-houses on view, also beating apparatus.

Syringes and spraying apparatus are shown by Messrs. Benton and Stone, Birmingham, including pumps in various forms, one of the knapsack pneumatics having a mechanical agitator, which is a great advantage.

Messrs. D. Roberts and Son, Tottenham, show plant tubs of excellent design and finish, garden seats and furniture.

Boilers of sectional form, exhibited by Messrs. Höttsch and Co., Guildford, are also on view.

A useful and varied selection of well-made garden tools is staged by the Hardy Patent Pick Company, Keeley, Sheffield, which should prove of interest to all gardeners, whether professional or amateur.

Vermorel spraying machines of varied sizes and types are on view and displayed in tasteful form by Messrs. Cooper, Pegler and Co., 24, Christopher Street, E.C.

(Continued on page xx.)

THE ROSE GARDEN.

TOP-DRESSING ROSE-BEDS.

A TOP-DRESSING is beneficial in all seasons, but it will be doubly helpful this year, considering the showery weather we are having. Of course, much depends upon what we have already given our Roses in the shape of fertilisers as to the material advisable now. One must be careful at all times not to apply a top-dressing, or mulch as it is sometimes termed that is going to close, as it were, the pores of the soil.

We all doubtless know how essential air and warmth are to the soil, during the growing season especially, hence our main object in hoeing the surface; but it is quite possible to apply such a top-dressing as will admit the essential air, and at the same time afford nourishment to the numbers of roots that abound upon healthy plants. If one has a number of weakly plants, it would be utterly folly to top-dress such plants with a powerful fertiliser; but to the strong, well-established specimens a top-dressing of such a composition as Wakeley's Hop Manure would be highly valuable. I have a high opinion of this compound, because I have proved its value; but I may here say that in spent Hops alone we have also a valuable ingredient, which, if lightly sprinkled with sulphate of ammonia, say, at the rate of half an ounce per square yard, will be very beneficial. The spent Hops may be applied, say, about an inch in depth, and then let the material be hoed or very lightly forked into the soil.

It must be remembered that Roses send out a lot of small feeders, which come very near the surface; hence the need for caution in forking up. To obtain the full benefit of sulphate of ammonia, the soil must contain lime in a good proportion, and the best time to apply this would be in the autumn. However, there are few soils that are really deficient of this article, so that one may safely apply the above now.

Another excellent top-dressing is compounded as follows: One hundredweight each of kainit, bone-meal and dried blood, mixed with about six bushels of rather dry soil, the whole well mixed together and placed in an airy, ramproof shed, and after two days apply a liberal dressing all over the beds, repeating this again in a month.

Some of the preparations sold by reliable firms are excellent for top-dressing, but the amateur is apt to be too liberal in their use. If applied well beneath the prescribed quantity and mixed with soil and well hoed in, they are of much fertilising value. Rape-meal is a splendid substitute for farmyard manure, and makes a capital top-dressing.

Apply at the rate of about four ounces to a square yard and fork it into the surface soil. As I said at the commencement, if the Roses were heavily manured in autumn or early spring, it may be they will not require a top-dressing, but instead give them some good liquid manure as soon as the buds are about the size of Peas, and continue this twice a week until the buds show colour. To Roses that appear somewhat weakly, a handful of rice compost, consisting of equal parts of fine soil and bone-flour, spread around them will be helpful, and they may have in addition a very weak solution of liquid cow-manure once a week. If any difficulty

ROSE MME. EDOUARD HERRIOT, A BEAUTIFUL NEW VARIETY SHOWN BY MESSRS. G. BECKWITH AND SON AT THE CHELSEA SHOW.

is found in obtaining spent Hops, old hot-bed manure, well broken up, can be utilised; in fact, if this is available, then the Hops will not be needed.

Peat-moss litter I do not care much about, as it settles down too closely. If dug under, there is less danger on this head, but I would avoid it if possible. In such a dripping season as it is there is little need for the ordinary mulch, save upon very shallow, gravelly soils. In their case it cannot but be useful, and it is surprising in what a shallow soil Roses will thrive if they are well fed by top-dressings followed with good and frequent stirring of the surface and applications of weak liquid manure whenever the plants show signs of exhaustion.

DANECROFT.

TREES AND SHRUBS.

STRONG-GROWING CLIMBERS FOR PERGOLAS.

CLIMBING Roses are so popular for planting on pergolas that many rely upon them entirely and take little account of the many climbing plants of other kinds which are suitable for the purpose, notwithstanding the fact that they have much to commend them either by reason of ornamental foliage or showy flowers. All climbers are not, however, suitable for pergolas, those of weak growth perhaps least so. Plants of weakly growth fail to attain the luxuriance of their stronger companions; therefore when planted together the effect is gappy, a condition fatal to the generally-accepted idea of the appearance which a pergola should present. In the following notes attention is directed to various strong-growing climbers which may be used for the purpose.

The Wisterias are perhaps the most beautiful of all flowering climbers for planting against pergolas, and at no time are they seen so effectively as when grown in such a manner. The pendulous racemes of flowers hang gracefully from both pillars and cross-bars, their delicate colouring and perfume being highly appreciated by all. Although the common *W. chinensis* is very beautiful, it is doubtful whether it is so generally useful for the purpose as *W. multi-juga*; but the latter plant must only be planted against pergolas of considerable height, for the pendulous racemes are often 2½ feet to 3½ feet in length. The colour is mauve, but there is a variety, *alba*, with white flowers and rather shorter racemes.

The new *Actinidia chinensis* is another decorative climber. Its assets are the bright brownish hairs which cover the young bark, large, heart-shaped leaves, and the yellow flowers, which are about one and a-half inches in diameter. In China it is considered useful on account of its edible fruit. *Celastrus articulatus*, a near relative of the common

Spindle Tree, is less frequently seen than its decorative qualities warrant. Forming long, strong branches, it may be expected to cover the highest support in a comparatively short space of time. Its fruits are its chief attraction, for when ripe they are highly coloured, the outer part being yellow and the covering of the seeds orange scarlet. As the fruits ripen, the outer covering bursts, disclosing the brighter seeds within. In this condition they remain from September to Christmas. The flowers are inconspicuous. *Akebia quinata* and *A. lobata* are a couple of strong-growing climbers which belong to the Berberis family. In the former case the five-parted leaves, and in the latter case the three-lobed leaves, are decidedly ornamental, while the purple flowers appear in profusion in spring.

Jasminum nudiflorum is well known as a winter-flowering climber, covering walls and trellises; but it is equally desirable for a pergola. The fact must always be remembered, however, that it must not be pruned at any other season than late winter or very early spring, otherwise the flowering wood will be cut away. The summer-flowering *Jasminum officinale* is also an admirable climbing shrub, for it grows well and its fragrant, white flowers always find admirers. There are several Honeysuckles which are worth attention. The common wild *Lonicera Periclymenum* and its various forms are among the best, while the Chinese and Japanese *L. japonica* is both free-growing and free-flowering. The varieties *chinensis*, *flexuosa* and *halliana* are equally worthy.

Where the garden varieties of *Clematis* can be depended upon, they make admirable subjects; but, unfortunately, there are many gardens where they behave in an unsatisfactory manner; therefore in those gardens it is advisable to rely upon species and botanical varieties. *Clematis Flammula* makes a most effective object in August when covered with its small, white, sweet-scented blossoms, while its variety *rubro-marginata* is also attractive. Earlier in the year, May and early June, *C. montana* may be expected to produce a wealth of bloom, the flowers being white; while

rounded leaves are dainty and attractive, while it bears bunches of black berries. *Periploca græca* is another climber which is not often met with. It grows vigorously and bears purple flowers in summer.

Several of the new kinds of Chinese *Rubus* are well worth planting against pergolas, particularly *R. bambusarum* and *R. flagelliformis*.

Numerous species of Vines may be obtained which have highly ornamental foliage; in fact, a pergola of considerable length might be made very interesting with Vines alone. Among others, *Vitis Labrusca*, *V. henryana*, *V. Thunbergii*, *V. Coignetiae*, *V. armata*, *V. Leeoides*, *V. megalophylla* and *V. Thomsonii* are specially noteworthy. *V. megalophylla* is a particularly ornamental kind, for its much-divided leaves are frequently upwards of 1½ feet across. *V. Leeoides* is also remarkable for its pinnate leaves.

In the South and West of England a very pretty white-flowered climber is often seen covering walls and fences. That is *Solanum jasminoides*. It is equally suitable for pergola planting, but may only be grown in the warmer parts of the country. The Trumpet Flowers, *Tecoma radicans* and *T. grandiflora*, grow quite well in many gardens, but must only be planted in sunny positions, else they will fail to perfect their flowers.

when in flower, the numerous-divided leaves render the trees ornamental at other seasons, while in winter there is much to admire in the picturesque trunks of old specimens of the False Acacia (*Robinia Pseudacacia*).

Robinia hispida (the Rose Acacia) forms a beautiful bush up to 6 feet or more in height, with Fern-like foliage. The branches are clothed with stiff, bristly hairs reddish brown in colour; hence the name *R. hispida*. The rose-coloured flowers are freely borne in pendent racemes. The variety *macrophylla*, illustrated below, is a far finer plant than the type, having much larger leaves and flowers, while it lacks the bristly hairs so notable in the common Rose Acacia. The flowering season is June. A little attention is necessary in pinching and pruning the bushes in a small state, as, naturally, the habit is rather straggling. *R. hispida* does not produce mature seeds under cultivation, and even in a wild state good seeds are rarely, if ever, found. Fortunately, the bushes sucker freely, and propagation is also possible by root-cuttings. Pieces of root as thick as a pencil and 3 inches or 4 inches long will grow if taken off in early spring and started in a propagating-frame. The variety *macrophylla* can be grafted on the type or the False Acacia (*R. Pseudacacia*). The year 1758 is given as the date of introduction of the Rose Acacia from the Southern United States.

R. neomexicana.—A native of Arizona, Colorado and New Mexico, this species was introduced as recently as 1887 into British gardens. In a wild state it is found as a small tree 20 feet to 25 feet in height. The pinnate leaves are interspersed with racemes of white flowers flushed or tinted with rose.

R. Pseudacacia (the False Acacia or common Locust) is the most popular *Robinia* in parks and gardens. It is quite at home in this country, attaining a height of 50 feet to 70 feet or more. Introduced from the Eastern United States in 1640, plenty of old, picturesque specimens exist in this country. The timber is notable, being very hard and durable. The elegant Fern-like foliage is very attractive. In June the trees produce quantities of white flowers in racemes. The False Acacia is useful as a street and town tree, thriving quite well in the London district, though in recent years it has been superseded by the variety *inermis*. Something like forty varieties or sports from the type have been given distinctive names. The most useful and distinct of them all are the varieties *bella rosea*, rose-coloured flowers;

bessonianiana, a tree more formal in growth; *decaisneana*, a French variety with deep pink blossoms; *fastigiata*, a tree very upright in growth, like the familiar Lombardy Poplar; and *inermis*, a thornless, small tree, a favourite for street planting.

R. viscosa (the Clammy Locust) grows 30 feet to 40 feet high. In the *Botanical Magazine*, t. 560, it is figured under the name of *R. glutinosa*, both names referring to the sticky glands on the young twigs and leaf-stalks. The pale rose-coloured flowers are borne at the end of June, thus being later than those of the common species. It was introduced to Britain about 1797, and is a native of the Southern United States.

A SPRAY OF THE ROSE ACACIA, *ROBINIA HISPIDA MACROPHYLLA*. THIS IS A BEAUTIFUL SHRUB THAT FLOWERS IN JUNE.

a good companion plant may be obtained in the variety *rubens*, which has red flowers. *C. orientalis*, with yellow flowers; *C. campaniflora*, with pale mauve flowers; *C. grata*, with white, violet-tinted blossoms; and *C. Durandii*, a hybrid with bluish flowers, are other desirable kinds.

Aristolochia Siphon, sometimes called the Dutchman's Pipe on account of its peculiarly shaped flowers, is another useful pergola shrub, for, in addition to its being of rampant growth, its large, deep green leaves are decidedly ornamental. Although rarely met with outside scientific establishments, the Moonseed (*Menispermum canadense*) might well be included as a pergola plant. Its

As a rule, these climbers are only seen at their best when planted in really good soil; hence the necessity of making sure that the soil conditions are right before planting, for no amount of top-dressing afterwards will make up for inferior soil about the roots.

ROBINIAS OR FALSE ACACIAS.

Among the large number of leguminous trees and shrubs cultivated outside in this country, the Robins or False Acacias hold an important position as ornamental subjects. There are five species, all natives of North America, and a considerable number of varieties. Very attractive

GARDENING FOR BEGINNERS.

A SIMPLE ARRANGEMENT OF SUMMER BEDS.

DIFFICULTY is sometimes experienced by beginners in deciding how to plant their flower-beds in a way which would produce good effect during the summer months and at the same time be of simple design. The beds illustrated on this page are very simple in form, and are planted with effective subjects; and although a block of beds is represented, this need not prevent any form of beds which may be dotted about the garden being planted with the subjects recommended.

The centre bed is to be planted with that very fine *Pentstemon* Southgate Gem in a carpet of *Viola* White Swan. The *Pentstemon* should not be planted too thickly. Give the plants plenty of space, viz., 18 inches to 24 inches between the plants, and fill in with the *Violas*. The plants should have been rooted from cuttings inserted last autumn. Placed in small pots in March last, the *Pentstemons* should by this time be well established and ready for planting in the beds. The *Violas*, formerly rooted under hand-lights, should also be ready for transferring to the beds in which they are to flower well into the autumn months. As a matter of fact, this bed would continue to flower well into November unless very sharp frost put an end to the flower-spikes of the *Pentstemons*.

No. 2 beds will also prove effective and lasting. *Begonia* Hilda is a very fine bedding plant. Each plant should have ample room to develop, filling the space between the plants with *Alyssum* Little Dorrit, which can be raised from seed in a very short time, and which will continue to flower well into the autumn.

No. 3 are planted with *White Intermediate Antirrhinums*, and, although not shown in the plan, pale blue *Violas* may be planted with them. If, however, this is done, the *Antirrhinums* must be planted 18 inches apart, in order to give the *Violas* room to develop. This I leave to the discretion of the planter.

No. 4 are planted with yellow *Begonias*. Either the single or double variety may be used. If it is decided to use the double, see that the flower-stems hold the flowers well up above the foliage, or choose an erect-growing variety. *Sedum glaucum* is used as a carpet plant. This *Sedum* has the merit of keeping the soil cool and moist, a condition of things very essential to the *Begonia*.

As above stated, it is not at all necessary or intended that the scheme of planting should be confined to a formal set of beds. It is equally suitable for any kind of bed, whether isolated or one of any number.

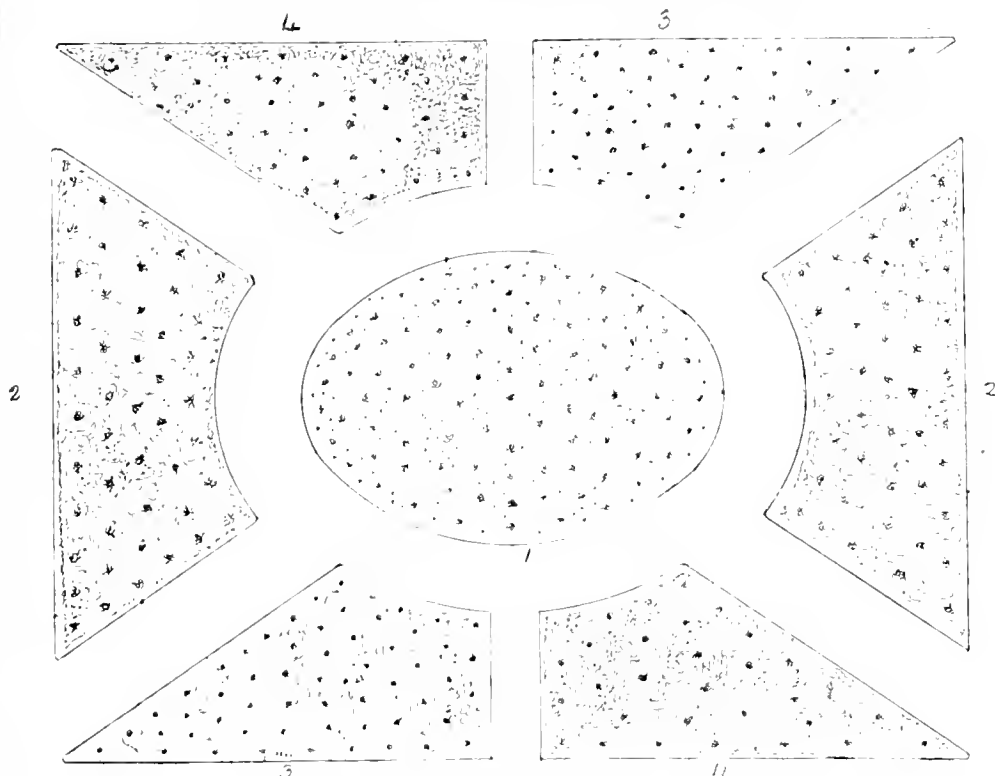

A. T.

HOW TO HARDEN BEDDING-OUT PLANTS.

THE time has come when hundreds of thousands of bedding-out plants will be placed in the open air to get inured to the outside temperature before being planted in the flower-beds. It is necessary, and wise, too, to see to this work very carefully. With the exception of *Calceolarias*, *Marguerites* and a few other kinds, which only need frost being kept from them in winter-time, all should be gradually exposed to the air. It is, however, a

fact that many inexperienced cultivators are too rash in thus exposing their plants, and so cause them to be checked and even much disfigured. A sheltered position must be selected, but not one unduly overshadowed by tall trees or buildings. A bed of asbes is a good base for the pots and boxes. A few laths or Pea sticks supported by forked pegs will bear up a thin covering material such as scrim,

from the ground to enable the workman to walk round it freely. Then he must put in a lining of very fresh moss, pressing it firmly to the sides of the basket, and filling up with compost and plants as the moss is placed in position; then the roots of the smaller plants which are grown through the sides can be better arranged in the soil as the work proceeds. It is very important that a good

SOME SIMPLE ARRANGEMENTS FOR SUMMER BEDS. THE SCHEMES ARE SUITABLE FOR SEPARATE BEDS AS WELL AS A SET AS SHOWN

and this should be put on for a few days at first; then for a few days only while the sun shines. Do not water the foliage while the sun is shining on the plants; then there will be no danger of scalding the leaves.

B.

HOW TO FILL FLOWER-BASKETS.

A BASKET in a window, porch, or several in a greenhouse, neatly filled with flowering and foliage plants, look very charming indeed. Beautifully-furnished baskets may very often be seen, but there are many also which are not an improvement to the appearance of the structure in which they are placed. Plants grown in pots are generally well prepared for establishment on stages and similar places, and so, also, should plants grown in hanging baskets be well prepared.

Failure is often courted by inexperienced cultivators putting the plants in the basket and forthwith suspending it in the bright sunshine under the glass. The best way is to fix the basket on a wire or strong piece of cord at a convenient height

run of sound moss be built up at the top of the basket, and also that sufficient space be left to hold water. A mistake is very often made in both respects.

The Compost should be a good one, and, generally, it must contain some fibrous loam and well-rotted manure. When the basket is filled, water carefully and syringe the sides. Unsuitable plants are sometimes used, and then disappointment is sure to follow. *Fuchsias* or similar graceful plants form good centre subjects. Ivy-leaved *Pelargoniums* are very effective indeed. The Zonal *Pelargoniums* may be employed, also *Coleuses* and *Petunias*. For shaded positions, *Ferns* in their pots look well in the centre, with pendulous-growing *Fuchsias* to depend from the sides of the basket. *Selaginellas*, *Panicum variegatum* and *Tradescantia zebrina* form a lovely covering to the sides of the basket. When the baskets are finished, place them in a shaded part of the greenhouse for ten days or a little while longer, keeping the plants syringed or watered to establish them, and then put the baskets in their summer positions.

SHAMROCK.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Preparations for Bedding-out.—Now that early-flowering bulbs are over, preparations may be made for summer bedding. Several of the groundwork plants may still be making a good show; but as our summer season is usually so short, no time should be lost in getting the beds ready for planting, especially where there is a lot of them to do.

Removal and Care of Bulbs.—Hyacinths, Tulips and Narcissi, after being lifted so early in the season, are not to be relied upon to make a good show in the beds another season, but by careful lifting and laying in light soil in a semi-shady position, they should be quite good enough for planting in borders or for naturalising in grass next season, this latter applying more particularly to the different varieties of Narcissi.

Arabis and Aubrietia should also be carefully lifted, and, after being carefully cut over, planted in a border to provide stock for next season, the former to be propagated from cuttings and the latter by division.

Polyanthuses also should be lifted, splitting up the best varieties and planting in nursery beds where they can remain till the autumn. In each instance it may be necessary to give the plants one or two waterings to establish them, especially if the weather is hot and dry.

The Rose Garden.

The Rose Maggot.—Though there are many very efficacious insecticides on the market, I have not found one that can be relied upon to kill these grubs, and to rid the plants of this pest they must be systematically looked over, killing the insects between the thumb and finger.

Aphis, too, makes its appearance very early, and to keep the plants quite clean they require spraying with an insecticide at least once every week, a carefully-prepared paraffin emulsion being one of the most effective remedies, and the Holder Pneumatic Sprayer is perhaps the most economical method of applying it.

Disbudding or thinning the shoots has to be practised where really good blooms are required, this being more necessary where a close system of pruning is practised. All weak shoots should be removed as soon as they attain an inch or 2 inches in length, leaving the strongest and best-placed shoots to bloom. This thinning applies equally as much to standards as to dwarfs, though in the latter case more shoots should be left so as to leave a good, full and shapely head.

Plants Under Glass.

Fuchsias, Begonias and Gloxinias are all plants that are benefited by a little shade, and the same applies to *Streptocarpus* and *Celosias*. If roller blinds are not fixed to the houses occupied by such subjects, a little permanent shading should be put on, starch and whitening carefully mixed and put on thinly being sufficient to stop the full glare of the sun without impeding too much light, and this will last the season through quite well and come off easily when desired.

Chrysanthemums.—The most forward plants of the large-flowering section will now be ready for their final potting, and the strongest growers should be put in 11½-inch pots. A moderately rich loam, with the usual addition of short manure, leaf-soil, cinder ashes, lime rubble, bone-meal and sand, is the best for them, and good, firm potting is necessary to secure a steady and well-hardened growth. Sufficient room should be left in the pots to allow of three or four slight top-dressings later on in the season. The plants should be fairly moist at the time of potting, and they must be well watered in before the ball of old soil gets really dry, or a loss of foliage will probably result.

The Kitchen Garden.

Parsnips should be thinned when nicely in the rough leaf, and if fairly strong might be finished right off at the one thinning, say, to a foot or 15 inches apart, after which give a good sooting and break up the ground nicely with the hoe.

Early Carrots also may be thinned to the requisite distance apart. If of the Shorthorn varieties, 4 inches to 6 inches is sufficient space to allow them; but the longer varieties should be allowed from 9 inches to 1 foot apart. Where there is any fly on the foliage, it should be carefully sprayed with paraffin emulsion or some other insecticide.

Runner Beans in boxes or pots and Sweet Corn should be gradually hardened off preparatory to planting in the open; also Marrows and Gourds, as after this week one feels comparatively safe from frosts here in the South.

Fruits Under Glass.

Early Muscat Vines that are stoning must be very carefully handled just now, the least inattention to airing in the early morning often resulting in scalded berries, and after being well thinned the scalding of only three or four berries will often spoil the appearance of a bunch. Plenty of moisture is very necessary at all times now, but an excess of it in the atmosphere as the temperature rises, with insufficient ventilation, often results in scalding.

Front Ventilation on Muscats I am not at all in favour of, particularly if the house is fairly high at the eaves. I think this is more productive of red spider than anything else, a draught of air right through the house drying the atmosphere far too quickly.

Hardy Fruit.

Figs on walls and in sheltered positions are now pushing forward their fruit, the somewhat mild winter being favourable to them. Where the roots are partially confined, a good soaking of liquid manure at this stage will help them very much, but it is hardly wise to give it to them unless it is noted that the fruit is swelling a little.

Forced Strawberries that have come through the houses in a clean condition may be planted (if required) to make up a permanent bed, and such plants, especially of the variety *Vicomtesse Hélicart de Thury*, will often give a very fair crop of fruit in August and September. Needless to add, watering will have to be resorted to until the plants get a good hold of the soil.

THOMAS STEVENSON
(Head-gardener to E. Mocatta, Esq.)
Woburn Place Gardens, Addlestone, Surrey

FOR NORTHERN GARDENS.

The Flower Garden.

Bedding-Out.—Beds which have been occupied by Wallflowers should receive an extra supply of manure, as these exhaust the soil very much. Where *Begonias* are to be planted, the ground should have a good admixture of flaky material, such as old Mushroom manure or good leaf-mould, plus bone-meal. The hardier things, such as *Geraniums*, should be planted first, the more tender things, such as *Begonias* and *Cannas*, being left till the last.

Dahlias.—The plants should now be fully exposed, but planting should be delayed till June comes in, especially in districts where late frosts are of frequent occurrence.

Planting Auriculas and Primroses.—Where these are dotted about the herbaceous beds and borders, and it is the intention to increase the stock or to replant more deeply, this is a good time to do so; and as these plants all incline to get leggy, they should be planted so deeply that the lower leaves will be almost at the ground-level.

The Reserve Garden.

Spring Bedding.—Many subjects will now have to be removed from the flower garden and planted in the reserve garden. They will include *Arabises*, *Primroses*, *Polyanthuses*, *Auriculas* and *Daisies*. *Arabis* can be planted without roots, which it will soon make if planted deeply and firmly. All the others named should be broken up, according to the size of the plant, and planted rather deeply in lines about one foot apart and from 6 inches to 9 inches apart in the rows.

The Rose Garden.

Aphis.—Many of the Hybrid Teas will soon be in flower, and, before, this occurs, care should be taken that the bushes are free of aphis. As already suggested, *Quassia Chips Extract*, *XL All Liquid Insecticide* or soapsuds may be applied with equally good results.

Suckers.—A close watch must be kept for these, and they should be removed at once.

Climbers.—It is a waste of energy to allow a number of superfluous shoots to develop and then cut them away. By removing these now the vigour of those retained will be increased by means of the extra sap and light at their disposal.

Plants Under Glass.

Hibiscus Manihot.—This erect-growing *Hibiscus* makes an excellent conservatory plant, its one drawback being that the individual blooms are short-lived. Seeds sown early in spring will yield a batch of plants which will bloom in autumn, but seeds sown in heat now will give nice strong plants for next season. The plant requires a warm greenhouse temperature.

Perpetual Carnations.—Young stock in 3-inch pots should be potted on, using 5-inch pots. Good yellow loam, with the addition of a little sharp sand, wood-ashes and dry cow or sheep manure, will suit them at this juncture. All young stock will now be better in cold frames, which should be well ventilated. Vaporise for aphis.

Fruits Under Glass.

Thinning Late Grapes.—This work is sometimes apt to be overlooked in the height of the bedding-out season. It is work, however, which, if delayed, becomes increasingly difficult, and should therefore receive attention at all hazards. I repeat the advice given on this subject earlier in the season—see that hands and scissors are clean, use a forked piece of wood for manipulating the bunches, retain the largest berries so far as is consistent with equal distribution of these, and preserve the full circumference of the bunch.

Ventilation Overnight.—Unless the weather is cold and gusty it is an advantage to leave a chink of air on overnight, and in the case of early crops beginning to show colour it is specially advisable.

Tomatoes.—Continue to feed the earlier crops in pots, but see to it that the plants are not really dry at the root when the feeding is applied. Continue to tie later crops and see that all lateral shoots are promptly pinched out.

Melons.—Where fruits are ripening, water must be gradually reduced. Fruits are sometimes cut too soon by those who are inexperienced. Two tests are applicable—a well-ripened fruit should have a rich aromatic scent, and should begin to crack round the stalk.

The Hardy Fruit Garden.

Gooseberries for Tarts.—These are much in demand in most establishments, and in some gardens a proportion of *Whinham's Industry* is grown specially for this purpose. If, however, the crop is an average one and the fruits are judiciously thinned, the general crop will be improved rather than injured by the removal of a proportion of the fruits at an early stage.

Caterpillars.—Should this pest assert itself it may still be annihilated by spraying with arsenate of lead, as previously directed, but the fruits must not be used within a month of its application.

The Kitchen Garden.

Planting Celery.—This work will now require attention. As indicated in the calendar last week, the width of the trench and the number of rows to a trench are immaterial matters provided each plant is allowed from 12 square inches to 15 square inches to develop. Give a good watering after planting.

Staking Runner Beans.—This work should receive attention as soon as the growth is a few inches high. Tall bare branches, or sawn stakes similar to those used for Hollyhocks—undressed, of course—will suit them.

Sowing Kidney Beans.—A late sowing should be made within the next week. If the ground is dry, water the seed lines well after sowing, and do not allow the seed to become dry till germination takes place.

Herbs.—Plant out those which were raised from seed.
CHARLES COMFORT.
Broomfield Gardens, Davidson's Mains, Midlothian.

CHRYSANTHEMUM NOTES.

PLANTS FOR THE FLOWER GARDEN.

THE early-flowering varieties are not grown in the flower garden as extensively as they deserve. Dahlias, too, may be associated with them, but in separate beds, of course. Many amateurs have in their gardens nice box-struck plants at the present time. These should be planted out during the latter part of May or early in June in the beds in which they are to flower. The soil should be enriched with well-rotted manure, and, if of a heavy nature, properly broken up. The young Chrysanthemums will soon get established, form side branches and make neat specimens, flowering, according to variety, from July to November.

In many gardens there are corner or out-of-the-way beds which, if filled with Chrysanthemums, would provide flowers for cutting and placing in vases. The best effect is obtained when distinct varieties are planted in each bed, but a border in an obscure part of the garden may be filled with a number of varieties. July, August and September flowering varieties may, with good effect, be associated with other kinds of bedding-out subjects, such as Fuchsias, Lilliums, Lantanas and Heliotrope. Directly the plants—growing in separate beds—are established and have formed plenty of new roots, commence to feed them, diluted cow and stable liquid being very beneficial. Those plants growing with other kinds must not have manure-water, except in cases where the soil is very poor, as a too gross growth of the other subjects might result. Many varieties of the early-flowering singles look charming in the flower garden.

Pompons for Cutting.—In a cosy corner in the vegetable garden, or other suitable quarter, a nice batch of Pompons may be planted for supplying cut blossoms for small as well as large vases in the autumn. I have grown them in this way for many years with great success, using small sprays for low vases on the tables, and cutting them with long stems for placing in the tall trumpet vases either by themselves or mixed with the large-flowered sorts. In any form they look charming in vases. It is advisable to plant these varieties in rows about three feet apart in a border, so that it will be quite convenient to put on a temporary covering in the autumn to shield the flowers from early frosts, as the blooms continue to open throughout the months of October, November and a part of December. Mats and scrim drawn over a skeleton lath arrangement will form sufficient protection as a rule. AVON.

THE FIFTY BEST MORaine PLANTS.

THE selections of fifty best alpine which have appeared in recent issues have created so much interest that I am now asked to give my personal list of fifty best plants for the moraine. The conditions of this selection are different from those of the last. In the first place, the question is far less general and the experience much less diffused, complete, and of old standing. Each moraine, like each gardener, has its special favourites, and the pet results of one moraine are not necessarily those of its neighbour across the

wall. Again, the moraine being a very special affair, there is no need in this choice to trouble about "utility" plants, such as the Aizoon Saxifragas, which will grow anywhere. I mean to allow myself, in fact, an orgy of special treasures, in repayment for the cruel excisions I was forced to make in the general list; since it is for these that the moraine exists. As to the conditions of this, let me postulate a moraine of some three parts chips to one part good compost of peat, leaf-mould and sand (a larger percentage of soil than I have suggested hitherto), watered by a subterranean perforated pipe some 12 inches to 15 inches down, but sharply drained; for more and more do I grow to distrust cemented bottoms, unless, indeed, your slope is very specially rapid and your climate of a very specially Saharan torridness. And in this mixture, then, I will allow myself a free hand in choice, and advise my friends to follow it without fear of disappointment if they succeed. But it must be remembered that my selection is purely personal, haphazard and incomplete. Many things are omitted simply as untried, such as Dryas; and my own blank failure hitherto with most Gentians and *Potentilla nitida* in the moraine is very likely a mere matter of conditions—a little soil the more, or some question of treatment—though I confess to doubting Gentians as a family for the moraine, despite the fact that one of my *G. Clusii* is now wearing a beautiful flower. But in one place very often I think a given plant enjoys moraine, and yet refuses to put up with another apparently like it somewhere else, where, perhaps, the conditions are not precisely such as to suit it. It was some time before any of my moraines suited *Dianthus neglectus*, which forms huge, grassy masses in open and rather inferior soil here.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Pæonia arborea La Lorraine.—A remarkable hybrid Tree Pæony, said to have originated from the crossing of *P. Moutan* with *P. lutea*, MM. V. Lemoine et Fils, Nancy, being the raisers. The flowers are very full and double, somewhat formal in outline, five inches or so across, and of a buff tone, passing to yellow. The bases of the petals low down are of a reddish colour. The foliage is glaucous. Exhibited by Messrs. J. Piper and Sons, Bayswater.

AWARDS OF MERIT.

Heliotrope The Speaker.—A dark-coloured, richly-perfumed variety with large trusses of flowers. From Mr. P. Ladds, Swanley.

Rose Miss Flora Mitten.—A perfectly single-flowered Rose of great charm, by reason of the large saucer-like flowers of pinky white, which appear in big clusters on greenish, almost thornless growths. The foliage, too, is large and hard-looking. A good climbing Rose. From Mr. J. Elliott, Hassocks, Sussex.

Rhododendron Rose Queen.—The name is somewhat descriptive of a beautiful variety, which is also very freely flowered. The flowers are drooping, warm rose pink without and paler within.

Rhododendron Wightii.—A beautiful variety with creamy yellow bell-like flowers. The foliage is green above and fuscous brown below, save for the midrib, which is pea green. Both came from Miss Clara Mangles, Littleworth, Seale, Surrey.

Aster Purdomii.—The plant, which is 9 inches high, is a recent introduction from China, the

Ingleborough, Lancaster

REGINALD FARRER.

florets coloured a lilac mauve. From Messrs. J. Veitch and Sons, Limited, Chelsea.

Thunbergia Gibsonii.—A remarkable plant from East Africa. The flowers are self-coloured and of a rich, refined orange tone. Of apparently perennial duration, the plant would appear to be a ground creeper, though would probably climb with age. As shown, flowers or buds were appearing from almost every leaf-axil, the pedicels being about six inches high. The leaves are almost rhomboid, lobed and somewhat hairy. From Mr. William Van der Weyer, Corfe Castle, Dorset.

Carnation Lady Shrewsbury.—A very full, handsome pink-flowered variety that is sure to find many admirers. From Messrs. William Cutbush and Sons, Highgate, N.

Tulip Massenet.—A very handsome Darwin variety, rose pink coloured externally and flesh-tinted within. It is a beautifully shaded flower, cream and pink, pleasingly associated, and in fine contrast with the electric blue and green coloured base. From Messrs. Bath, Wisbech.

NEW ORCHIDS.

New Orchids to gain awards of merit were *Brasso-Laelio-Cattleya Veitchii* The Dell, from Baron Bruno Schröder; *Laelio-Cattleya Fascinator* × *Mossia*, sent by Sir Trevor Lawrence; and *Odontoglossum Phœbe splendens*, from Messrs. J. and A. McBean.

The foregoing were shown before the Royal Horticultural Society on May 14, when the awards were made.

THE FRUIT GARDEN.

SPRAYING FRUIT TREES.

THE month of May is an important period to the fruit-grower, who has many enemies in the shape of insect pests to contend with. Having already seen the effect of winter spraying for the removal of moss and lichen from the trees, as well as the diminution of *Psylla* or *Apple-sucker* by the free use of lime and salt before the blossoms unfolded, I would like to advise those who have in the past been troubled with *Apple scab* that they need not now have their fruit disfigured by this fungus if they will but take the trouble to spray with *Strawsonite*, commonly known as *Bordeaux* mixture, at the rate of 15lb. of *Strawsonite* to 100 gallons of water. This spraying should take place directly the blossoms fall. Last year I commenced on May 14 with this mixture. Should the trees be affected with winter moth caterpillar, arsenate of lead can be used in conjunction with *Strawsonite*, thus saving the trouble of a second spraying. To 100 gallons of cold water add 10lb. of *Strawsonite* and 3lb. of *Strawson's Swift Arsenate*. The arsenate of lead is procurable in paste form. This should be dissolved first in a small quantity of water, adding it afterwards to the bulk when thoroughly dissolved. If the trees are carefully sprayed, *Apple scab* will be thoroughly exterminated, and I think all will agree, if this is so, that one of the greatest pests the *Apple-grower* has to contend with will have been eliminated.

In some seasons, when the fruit begins to swell after the spraying, a coating of rust may be seen

on much of the fruit; indeed, in some cases to an apparently alarming extent, so much so that the spraying is often blamed for this apparent disfigurement. Last year much of my fruit was so affected. I found, as time went on, this rust dispersed and did no harm, not even disfiguring the fruit. The cause is one of adverse weather at spraying-time. When cold and sunless, the tender skin of the *Apple* is affected by the chemicals used. If the weather were of a more genial character, this rust would not be perceptible. I take this opportunity to point out to the inexperienced what may happen, but to assure them no harm will follow, always supposing the materials used are of the best and the quantities recommended are not exceeded.

I never saw the trees so free from *Psylla* (*Apple-sucker*) as they are this season. *Warner's King* is profusely flowered, and this variety is one of the first to indicate the presence of this pest. On all the trees of this *Apple* I have not seen a single caterpillar as yet. If there is no sign of caterpillar, the arsenate of lead is not required. Simply use *Strawsonite* for the prevention of *Apple scab* (*Fusicladium deutricum*). *Cox's Orange Pippin* is more delicate in its leaf tissue and is liable to be damaged by the ordinary strength of spray fluid beneficial to other sorts, therefore should not be sprayed with so strong a solution. E. MOLYNEUX.

THE ROSE OUTLOOK FOR 1913.

So far as we in Mid-Sussex are concerned, the outlook for the coming *Rose* season is by no means black, and may be taken as about up to the average. We have lost but little wood through frost, and despite the only partial ripening of many varieties, the wood cut firm and promising down at the pruning point. I sometimes fancy we are more concerned about the fuller ripening of our *Roses* than we need be, and this seems more so since the advent of our *Hybrid Teas*, which do not mature their points of late growth so much as was the case with the older *Hybrid Perpetuals*. This is only natural when we consider that our present-day *Roses* consist largely of autumnal bloomers instead of summer flowerers only, as was the case of the majority before the advent of the glorious hybrids that are now more or less continuous right up to the advent of frost. In almost all cases this class of *Rose* matures its lower growth in a surprisingly good condition. One notes this soon after the second flowering growth has formed, and we generally have to cut back all of the third crop of growth, whether ripe or not. On the whole, our *Roses* are breaking evenly, and are not at all in a dangerously forward condition, especially when we take into account the remarkably mild season experienced in this district.

Transplanted *Roses* are looking fairly well, and those moved early in the spring are as sound as any planted during late autumn. The stocks, too, put out for working upon next summer are looking even, a few that were not earthed-up being the worst. Buds inserted in 1912 are up to the average, except in the case of a few varieties on standard *Briars*, which seem bound, much the same as we often find them after a severe winter. In this case we shall leave more young wood beyond the *Rose-buds* than usual for a time to encourage their breaking. A. P.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET-SCENTED PLANTS FOR NARROW BORDER (*Miss M.*).—You could not do better than plant *Stocks* of several sections to give a succession of flowers, with white *Tobacco* at the back and a bordering of the *Night-scented Stock* for the front. Of the first two you have to secure plants, while of the third you might still make a sowing where it would remain for flowering. You do not give the width of the border: hence we cannot gauge how much or how little may be required.

LILIUMS FROM SEED (*Redpits*).—Seeds of *Lilium giganteum*, and other kinds of *Lilies* also, are often very erratic in the way they germinate, especially if the seeds have been allowed to dry at all before sowing. They sometimes vegetate in six or eight weeks, and at other times lie in the soil for twelve months before any growth is noticed. It is not necessary to provide any considerable heat; an ordinary warm greenhouse will furnish all that is required. *Haakea eucalyptoides* will succeed in either a cool or a warm greenhouse. The seeds take from two months to six months to germinate. Sandy peat should be provided for this plant.

TREES AND SHRUBS.

INJURY TO MAGNOLIAS (*Shirimark*).—We think the *Magnolias* must be exposed to cold draughts. There is no fungus or insect upon them to account for the browning of which you complain.

CISTUS CUTTINGS (*Redpits*).—Cuttings of various kinds of *Cistus* should be taken in July. They should be made about three inches long and be inserted in pots or beds of sandy soil. If in pots, a good watering should be given, and the pots should then be plunged in fibre in a close, cool frame. Subsequent watering must be done very carefully, and the frame should be opened for half-an-hour or so each day to allow superfluous moisture to dry up. During bright sunshine a blind must be placed over the glass. If the cuttings are to be inserted in a bed, a bed of soil should be made up in a cold frame and the cuttings inserted 1 inch to 2 inches apart. A good compost consists of two parts good loam, one part leaf-mould and one part silver sand. The frame must be kept close until roots are formed, after which time air must be admitted freely. Young plants should be potted singly in small pots until they can be put out in permanent places, for they do not transpire well from the open ground. As a rule, cuttings root better in a cool than in a heated frame.

IS IVY POISONOUS TO OTHER PLANTS? (*Clossy*).—We have never had experience of *Ivy* roots being poisonous to other plants, and have frequently associated *Ivy* with other shrubs without noticing that anything unusual has happened to plants in the vicinity. In some gardens it is a common practice to combine *Ivy* with some other climber, such as *Clematis Jackmanii* or *Jasminum nudiflorum*, on walls, while *Ivies* of shrubby growth are constantly mixed with other shrubs in shrubberies. We do not think for a moment that the *Ivy* of which you speak caused the *Rhododendrons* to become unhealthy, neither is it necessary to take the precautions you suggest for shutting the roots of the *Ivy* out from the *Rhododendron*—that is an account of poisonous properties; but it might be advisable to cut the *Ivy* roots back to stop them from robbing the *Rhododendrons* of food material. *Hypericum calycinum* forms a good evergreen border plant for a shady place, but to keep it in good condition it should be cut back fairly hard each spring. There is no really good evergreen, self-clinging climber other than *Ivy*, but a good deciduous one is *Hydrangea petiolaris*. The latter climbs in the same way as the *Ivy*, by means of aerial roots. If *Ivy* were really poisonous to tree and shrub growth, it would kill trees and shrubs in woods, for there are woods which are practically covered with an undergrowth of common *Ivy*. In gardens it is a common practice to clothe the ground beneath trees, where grass will not grow, with *Ivy*, and neither one harms the other. We know such coverings where clumps of *Daffodils* have been growing among the *Ivy* for the last twenty years.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

NOTES OF THE WEEK.

Our Rock Garden Competition.—We would remind our readers that June 1 is the last day for sending in photographs of rock gardens for our competition, full particulars of which have appeared in many previous issues.

The Chelsea Show.—We wish to thank all those readers who have so kindly sent us letters of appreciation relating to our Special Double Number published last week. It was only by the aid of thoroughly up-to-date printing machines and a band of enthusiastic helpers that we were able to have copies at the show by 3 p.m. on Wednesday. Some of the photographs reproduced in that issue were not taken until 12 noon on the Tuesday.

Record of the International Horticultural Exhibition.—Now that a year has elapsed since the great International Horticultural Exhibition was held at Chelsea, it is not unreasonable to ask when the official record, of which so much was heard last year, is likely to be published? It would almost seem that the muddle which characterised many of the arrangements of an otherwise successful show is retarding the appearance of this long-promised volume.

Honour for Mr. R. A. Rolfe.—We are pleased to learn that the French Académie Internationale de Géographie Botanique has awarded to Mr. R. A. Rolfe its Scientific Medal in recognition of his work among Orchids. In addition to his valuable work in the Kew Herbarium, Mr. Rolfe has edited the *Orchid Review* since its commencement in 1893. The honour is conferred upon Mr. Rolfe at a fitting time, as it marks the coming-of-age of the *Orchid Review*.

Tulip Disease.—This is different from "fire" referred to on page 249 last week, and may be known by the stem decaying at or below the ground-level, so that it parts company with the bulb with the gentlest pull. Black spots, varying in size from a pin's head to a small Pea, are present on the bulb under the outer covering, and on the bit of stem left adhering to it. All the plants must be at once rooted up and burnt, and the ground not used for Tulips for at least two seasons.

Home-Grown Cascara Sagrada.—In recent years attention has been called to the possibility of this valuable laxative, prepared from *Rhamnus purshiana*, proving a remunerative culture in the British Isles. The bark collected from home-grown trees has been shown to possess medicinal properties indistinguishable from those of American cascara. Mr. W. J. Bean gives some interesting facts concerning the possibility of growing *Rhamnus purshiana* on a commercial basis in this country in a recent issue of the *Kew Bulletin*; but in his opinion, in view of the prices at present obtainable for cascara sagrada, it scarcely seems likely that it would prove a paying crop.

Testimonial to the Rev. W. Wilks.—We understand that the testimonial subscribed to by Fellows of the Royal Horticultural Society as an appreciation of Mr. Wilks' twenty-five years' work in connection with the Royal Horticultural Society was formally presented to him at his residence on Saturday last. We believe the amount subscribed exceeded £600. As we have already pointed out, Mr. Wilks has done yeoman service for the society for more than a quarter of a century, and its present flourishing condition is largely due to his enterprise and energy.

A Beautiful Bulbous Plant.—One of the most interesting and beautiful plants in the outdoor garden just now is *Habranthus pratensis*, a rather rare native of Chili, that many fail to grow really well. It was shown in good condition by a few exhibitors at the Chelsea Show last week. The flowers, which resemble those of a miniature *Amaryllis*, are vivid scarlet with a greenish yellow throat, and are borne on stems 1 foot to 15 inches high and from four to six on a stem. We have a little colony doing well on a south border, the soil being good, rather rich loam. Sun after flowering appears to be one of their principal requirements.

Roses with Beautiful Stems and Foliage.—Although Roses have not yet opened their flowers in many localities, the beds are not devoid of interest, for the young stems and foliage of many varieties are exceedingly charming. Take that beautiful Rose *Grüss an Teplitz*. Its dull crimson, mottled green leaves form a picture of rare beauty when kissed by the morning sun. Then note the glossy green of American Pillar, the deep crimson of *Marquise de Sinety*, the pale crimson and green of *Gustave Regis*, the blood red shoots and spines of *White Killarney*, and the red stems contrasting so well with the green leaves of *Miss Cynthia Forde*. All are beautiful in their way, and we hope this phase of Rose glory will receive its due recognition in nurserymen's catalogues.

Forget-me-not in the Pleasure Grounds.—The value of the beautiful blue-flowered *Myosotis alpestris*, as cultivated in masses in the pleasure grounds at Kew, is worth considering. It is comparatively little trouble, self-sown seedlings coming up freely in favourable positions. Very pretty effects are obtained when used as a groundwork in borders and large beds of shrubs. One particularly effective combination is the pale mauve pink *Tamarix tetrandra*, with the Forget-me-not as a groundwork. Beds or groups of the following shrubs, which are all pruned fairly severely in spring, because they flower in late summer and autumn, may be carpeted with *Myosotis*: *Tamarix pentandra*, *Hydrangea paniculata*, *Spiræa Aitchisonii*, *S. Lindleyi*, *Buddleia variabilis* and varieties, autumn-flowering varieties of *Ceanothus* and *Hypericum Henryi*. Self-sown seedlings, or plants sown where they are to flower, as a rule give a better carpet than when transplanted.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Carnation Lady Ingestre.—We were exhibiting at the meeting of the Royal Horticultural Society held on May 14 a new seedling Carnation, for which we received an award of merit. We find

MECONOPSIS DELAVAYI, A NEW AND RARE SPECIES WITH IMPERIAL PURPLE FLOWERS, SHOWN AT CHELSEA.

that by an error the bloom was named Lady Shrewsbury, which was incorrect; the name of the Carnation should have been Lady Ingestre.—WILLIAM CUTBUSH AND SON.

The Colour of Aubrietias.—Many as are the varieties of this good spring flower, I think we have not yet arrived at the very best type of colour for general gardening. It may be that, being unable to visit nurseries and private gardens, I am not in a position to judge; but it appears to me that the tendency with seed-growers is to push them too much towards reds and very strong red purples. We seem to want a type of good middle-strength of colour, but of the cooler rather than the hotter class; that is to say, inclining to the colour of lavender in the lighter shades and to that of violets in the darker. I fully appreciate the glorious colour of the variety Dr. Mules and the fine bloom of the one named Lavender; but a whole bank of Dr. Mules would be dazzling and yet a trifle monotonous, whereas a bank of the colour I have in mind, with a small drift of Dr. Mules or any one of the strong purples, would be not only more interesting, but, as I venture to think,

incomparably more beautiful. The fine variety Lavender is a little spoilt by the white eye, which cuts up the mass, and as it is a plant that one wants to use in quantity, it would be desirable that the whole colour of the flower should be as even as possible.—G. JEKYLL.

Aphis on Spruce.—Complaints from widely different districts are heard of the attack upon Spruce by the green fly (*Aphis abietina*). It is a fairly well-known pest, appearing here and there when conditions favour development, necessitating sometimes spraying with insecticide. This spring, however, the attack is much more severe than usual, every leaf on some trees of *Picea pungens glauca*, the Blue Spruce, turning brown and dropping off owing to punctures by the pest. By the side of the lake at Kew damage is being done, in addition to this plant, to the Sitka Spruce, *P. sitchensis*, *P. hondoensis*, the common Spruce, *P. excelsa* and varieties, and it is also spreading to the rare *P. morindoides*. The only suggestion advanced so far to account for the widespread destruction this year is the unusually mild winter, there not being sufficient frost to destroy the eggs laid in autumn. In Ireland, also, considerable damage is reported. Careful watch should be kept by everyone having charge of Spruce, whether the trees are few or many, as there is no outward appearance of the pest till the damage is done. It belongs to the same family as the common green fly of our greenhouses and gardens (*Rophalosiphon Dianthi*), but is much more destructive. Vigorous spraying with insecticide is necessary to check its spread. We are using a mixture of 2lb. of Quassia chips, 4 pints of paraffin, 1½lb. of soft soap, and sufficient Tobacco water to colour it brown, to 36 gallons of water.—O. A.

The Fifty Best Alpines.—In Mr. Smith's article on *Saxifraga burseriana* of your issue for May 17, page 238, he refers to the setacea group of Phloxes, which I did not include among my first fifty plants. My experience does not lead me to think that the chalk mentioned would improve our soil here to keep the plants from burning. I was something in the position of Mr. Farrer when suggesting my first fifty plants, having a large number over, which had to be reduced to fifty, and that was the reason of my leaving out this most beautiful section of Phloxes, as I have never seen them more beautiful than this year. The wet and showery time has just suited them. We have here some thirty large masses of these (in variety) from 1 yard to 2 yards across each plant, and they present a gorgeous display surrounded by Phlox reptans, *Lithospermum Heavenly Blue*, *Aubrietia Dr. Mules* and *Phlox divaricata Laphamii*. To see one of these grand masses burnt just when in full bloom is enough to make one weep. By some, plants are more there by name than anything else, and if it is a small plant, such as just turned out of a 3-inch pot, this burning is hardly noticed. Another great point of *Phlox reptans* is that it is in flower from April to October, and, after all, it is the array of flowers that creates enthusiasts, as take, for instance, the interest evinced in the flowers at any great show in looking over the great trade exhibits, and a little success for a start is better than so many failures.—G. F. HYLAND, *The Gardens, Ashby St. Ledgers, Rugby*.

Primula cockburniana.—Mr. Arnott raises an interesting point in the issue of THE GARDEN for May 10, page 229, when he asks how far is it perennial. The article throughout is brimful of interest to lovers of hardy flowers, and this *Primula*, which is in the eyes of some the most beautiful for

massing, is worthy of due consideration and collected knowledge. The plant is certainly a perennial, but, unfortunately, a difficult one, and the question naturally arises in one's mind: Is it wise to consider it a perennial or not? I say "No"; but give the world to understand that it is a biennial, and there will be no disappointments. Grown as a biennial, sow the seed as soon as ripe, prick off the seedlings in a sandy compost, and winter in a cold frame. Pot them singly in 3½-inch pots, when growth commences in the spring, in a sandy loam with the addition of a little leaf-soil and old cow-manure, and plant out in May in a well-drained bed in a half-shady position. Ordinary garden soil, with the addition of a good dressing of well-seasoned cow-manure and a liberal quantity of grit well mixed through the soil, forms a nice rooting medium, and in the autumn, before the leaves fade, top-dress with good loam, with one-third very coarse sand added. *P. cockburniana* is quite hardy, but damp it will not stand; therefore a deep and

CUPRESSUS LAWSONIANA FLETCHERI, A NEW DWARF SHRUB FOR THE ROCK GARDEN.

perfect drainage is the greatest essential in retaining a "perennial" habit, coupled with a position that stands dry in winter. Having grown this beautiful *Primula* in fairly large quantities since its introduction, I must confess that it has been a failure as a perennial.—D. L., *Sheffield*. [Our correspondent sends a photograph showing a splendid colony of this *Primula*, but, unfortunately, it was not suitable for reproduction.—ED.]

How to Grow *Ourisia coccinea*.—This troublesome subject is doing well and flowering in a rock bed at Terregles, Dumfries, the residence of Mr. C. E. Galbraith, where alpinists are doing admirably under the care of Mr. William Hutchinson, the gardener, and his staff. I know of a few gardens in this locality where it thrives well, notably the garden of General Stewart at Carruchan, Dumfries, where the *Ourisia* has grown and flowered well for years. At Terregles it is cultivated under entirely different conditions, being well above the ordinary level on a rock bed on the top of a low retaining wall, and in soil composed of about eighteen inches of ashes below, with about four inches of road grit and two inches of loam above. At Carnehan *O. coccinea* grows on the level, and in most places where I have seen it thriving it has been in a lower rather than in a higher part of the garden. It is just one of the plants about which it is impossible to dogmatise respecting its treatment, and those who wish to succeed with it will do well to try it in different positions and not be disheartened by a few failures. What is an ideal place according to the books is not always so in actual practice.—S. ARNOTT, *Dumfries*.

A Plea for Perfume.—I am most interested to find that at last the lack of perfume in so many of our otherwise admirable modern flowers is beginning to be commented on in print. It has long been lamented by genuine amateurs, and more particularly by those whose lot it is to live in towns. We continually find so-called Sweet Peas that are neither sweet nor shapely, and Roses that "by any other name" should "smell as sweet," but that are a snare and delusion in this respect. And now, with deep dismay, I read of an award of merit given by the Royal Horticultural Society to a Wallflower, as mentioned on page 239, issue May 17, lacking in fragrance. Words fail me (and it is as well they do, for if I could express my sentiments, you, Sir, would certainly have to run your blue pencil through them). As the gentle Elia owned he had "no ear," so it would seem that modern florists have "no noses"! I do most sincerely hope that now their attention is being drawn to the matter, our professional florists will amend their former naughty ways, and, ceasing to be obsessed by the American craze for mere size and conspicuous colours, they will restore to our gardens flowers with their former precious charm of fragrance.—ANNE AMATEUR.

June 9.—United Horticultural Benefit and Provident Society's Meeting.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

***Nephrolepis exaltata* Willmottæ.**—This remarkable variety, without doubt the least exalted of a wonderful series of forms, is characterised by great density, a low, spreading, almost prostrate habit, and quite diminutive fronds. It has already received an award of merit. From Messrs. May and Sons, Edmonton.

***Cupressus lawsoniana* Fletcheri.**—Promises well for the rock garden. It is a dwarf, compact-growing variety of the *C. E. erecto-viridis* type, but of a greyish glaucous colour. A neat plant of distinction and merit. See illustration page 274. From Messrs. Fletcher and Sons, Chertsey.

ROSCOEA CAUTILOIDES, A RARE SPECIES, SHOWN BY MESSRS. BEES AT CHELSEA.

***Meconopsis Delavayi*.**—Probably the most unique hardy plant novelty of the season. Four plants were shown less than six inches high, having roughish hairy entire lance-shaped leaves, and cupped flowers of almost imperial purple with rich plum purple shading. The cluster of golden anthers affords a fine contrast. See illustration page 274. From the Botanic Gardens, Edinburgh.

AWARDS OF MERIT.

***Campanula Stevensii nana*.**—The tufts, less than two inches high, as shown by Mr. Reginald Prichard, Wimborne, Dorset, crowded as they were with large pale blue sub-erect bells, were idolised by all lovers of alpine plants. It is quite a gem

***Pentstemon Davidsonii*.**—A miniature-growing species from the Rocky Mountains, having greyish, nearly ovate, slightly-notched leaves, and a sub-shrubby habit. The flowers are 1½ inches long and of rose-scarlet colour. The flowering plants, as shown, were 4 inches high. From Mr. Clarence Elliott, Stevenage.

***Auricula William Smith*.**—A fine green-edged variety of unusual vigour. The plant carried a superb truss of flowers. From Mr. J. Douglas, Great Bookham.

***Saxifraga Grandfieldii*.**—In all probability a seed sport from *S. aizoonifolia*, having flowers of snowy whiteness. The plant shown was nearly a foot high, and had been raised by the exhibitor at Hayes. From Sir Everard Hambro, K.C.V.O., Hayes (gardener, Mr. J. Grandfield).

***Calceolaria Clarefield Gem*.**—The flowers are bronze and yellow, the plant a free bloomer and nearly three feet high. From Mrs. Litke, Pinkney's Green.

***Rose Nancy Perkins*.**—A small-growing double white flowered variety of the Polyantha set. The plants as shown were not more than 9 inches high. Exhibited by Messrs. T. Perkins and Sons, Drapery, Northampton.

***Rose Irish Fireflame*.**—A single-flowered variety, characterised externally by a wonderful tone of coppery orange colour.

***Rose Mrs. Campbell Hall* (H.T.).**—A shapely and beautiful Rose of bluish pink colour for the most part, with almost salmon-tipped centre. These were from Messrs. Alexander Dickson, Newtownards.

***Rose White Tausendschon*.**—The name is descriptive and good, and everybody who knows the original will welcome this pretty bluish white sport of it, which is in every way good. From Messrs. William Paul and Sons, Waltham Cross.

***Begonia Lena*.**—The flowers are deep crimson scarlet and freely produced in a pendent habit, which fits it for basket work. From Messrs. Blackmore and Langdon, Bath.

***Roscoea cautiloides*.**—A distinct-looking plant with yellow flowers and long, cylindrically-ribbed tuberos roots. It is perhaps more quaint and distinct than pretty. From Bees, Limited, Liverpool.

***Sarracenia Brucei*.**—A very distinct and beautiful plant, having pitchers nearly two feet high. Of true trumpet shape, expanding in size as the apex is reached, the plant is remarkable for the brilliant colouring and venation of the lid and adjacent parts. These are handsome indeed. From Mr. A. J. A. Bruce, Chorlton-cum-Hardy, Manchester.

***Aster Falconeri*.**—It perfectly hardy and a true perennial, this will prove welcome. The florets are coloured violet blue, the flower-heads about four inches across. From Messrs. Barr and Sons, Covent Garden.

***Cylisus andreaea prostrata*.**—The varietal name appears strange when standard plants of

4 feet high are shown and a drooping habit revealed. The flowers are coloured yellow and brown. From Mr. L. R. Russell, Richmond.

Styrax Wilsonii.—Here is a delightful Chinese plant endowed with not a little of the grace and charm characteristic of its tribe. Only a small pot plant was shown, the lower branches having a lateral spread of 2 feet or more, from the under sides of which dainty tresses of starry, nearly pure white flowers dangled from short pedicels. The habit is elegant indeed. Shown by Miss Willmott V.M.H., Warley Place, Essex.

Lonicera tragophylla.—The yellow, tubular-formed flowers are fully 4 inches in length, and even on the small plants of 2 feet high, as shown, were present in goodly numbers. Exhibited by Messrs. James Veitch and Sons, Limited, Chelsea.

right use and right placing that will make the picture, and, in the case of the flowers, show what they can really do for our most complete enjoyment.

It is proposed to give a series of short notes suggesting how this may be done, and, for the sake of those who are beginners in this kind of arrangement, to name examples of good grouping that can easily be grasped and followed. Thus, for spring flowers (for greater clearness it will be convenient to take the groupings in four sections), each group or section should merge imperceptibly into the next, and, whatever the shape of the spring garden may be, it would be well to keep the sequence of colourings in the order here given:

1. *Myosotis dissitiflora*, double *Arabis*, pink Tulip *Rosa Mundi* or *Cottage Maid*, white Prim-

with such as the early *Artus* and ending with the splendid tall *gesneriana major*. Near the front, from the drifts, some of the reddish-folaged *Heuchera Richardsonii*.

These suggestions suppose a space of garden ground that can be given to the spring flowers and is not required for later gardening; for many of the best spring flowers, and all the plants of large foliage, such as *Veratrum*, *Solomon's Seal* and *Myrrhis*, that so greatly enhance the appearance of the flowers, have to remain some years in the ground.

It will be seen that several of the groups, or main parts of groups, are in close colour harmony. The comparatively slight difference of related colouring gives that most important quality of *gradation* that is a prime necessity in any good picture, while the fairly large spaces of each kind of colouring, combined with, and inseparable from this gradation, give an effect of richness and splendour such as cannot be obtained by any one unbroken mass of colour, however brilliant that colour may be in itself.

G. JEKYLL.

SOME GOOD BUT COMMON GARDEN PLANTS.

THERE are some good but common garden plants whose very commonness forms a bar to their cultivation. These, and some others not mentioned below, I have long made a point of finding room for, not, perhaps, in every case every year, for some of them are apt to die out and need reintroducing, and anyhow in these days, when so many good things clamour for recognition and the limits of space are a consideration, it is no loss to allow plants to go out of cultivation for a time, that others may have a turn. At the time of writing,

Honesty is one of the handsomest of flowering plants, not the common dirty lilac variety, but a deep purple crimson one which makes an effective blotch of colour. The white flowering *Honesty* is also desirable, for vase furnishing more especially. All the seminal variations produce nice cutting material when the seed-vessels are about half grown; and finally, as everybody knows, after the seeds have dispersed, the whitened disseminants are indispensable for decorating. These give the plant its quaint appellations of *Honesty*, *Silver Plate* and *Money-in-both-pockets*. *Honesty* possesses the happy constitution of thriving under the shade of Apple and other trees, and in some soils becomes somewhat of a weed, needing merely to be thinned to afford a sufficient number of specimens. It is excellent for the wild garden, grouped as shown in the above illustration.

The Red Valerian (*Centranthus ruber*) is like *Honesty* in respect of there being bad and good varieties. The finest is nearly crimson-flowered, the common wild form being of a colour not at all to be commended, and perhaps impossible to associate harmoniously with other flowers. There are both white and nearly white varieties. As a border plant it possesses the invaluable property of flowering from May till November. It is particularly suitable for wall culture. Many years ago

WHITE HONESTY IN THE WILD GARDEN AT HALLINGBURY PLACE, BISHOP'S STORTFORD

The foregoing awards were made at the Royal Horticultural Society's Exhibition at Chelsea.

THE FLOWER GARDEN.

GROUPING FLOWERS FOR COLOUR.

THE repeated requests for information and suggestion that have recently reached the Editor are a proof of the ever-increasing interest in the subject of grouping and arranging plants for colour effect. It is a significant sign of advance in the character of the aims of those who love their gardens. No one who has seen flower-borders or other garden spaces well arranged for colour effect would ever go back to haphazard planting. A garden may contain an ample supply of the best plants, and the gardener may be the most able of cultivators; but if the plants are not placed to good effect it is only like having the best paints from the best colourman. In either case, it is only the exactly

roses, white double Daisy, *Tiarella cordifolia*, white Tulip *Nelly* (short, early) and *White Swan* (taller and later); *Veratrum* at back.

2. palest *Aubrietia*, again double *Arabis*, *Phloxes amoena*, *Nelsoni*, *stellaria* and *divaricata*, *Corydalis ochroleuca*, *Alyssum*, *Tulipa retroflexa*, palest yellow Wallflower, yellow Primrose, Tulips *Chrysolora* (early) and *Golden Crown* (later), *Doronicum plantagineum*; at back *Sulphur Crown Imperial*, *Solomon's Seal*, *Veratrum* and *Myrrhis odorata*.

3. *Orobis vernus*, purple Wallflower, *Aubrietia* (middle and deep purple), purple Tulips, especially Rev. H. Ewbank (pale, moderate height) and the taller double *Blen Celeste* and the fine single *Morales*; dark purple *Honesty*, and again *Solomon's Seal* and *Myrrhis*. A few white Tulips.

4. Tulips *Thomas Moore*, *La Merveille* and *gesneriana aurantiaca* (they are named in the right succession for season and height, the first-named being the shorter and earlier); brown Wallflower in plenty, both tall and dwarf. At back *Berberis Darwinii* and one or two of the red-leaved dwarf Maples; a drift or two of scarlet Tulip, beginning

I introduced it on the garden walls by means of seeds mixed with soil scattered liberally on top of the wall. The plants from these and their progeny give bright splashes of colour for a longer time than any other plant. Usually known as the Red Valerian, the light variety goes by the names of Pretty Betsy and Delicate Bet, and the dark is Bonning Bet.

The Foxglove is, perhaps, next to the Hollyhock and some of the Verbascums, the handsomest of hardy flowering plants and the least difficult to grow. In this case, too, it is essential to be careful to grow only first-rate forms. Personally, I like the pure white better than any of the numerous coloured kinds—that is, for border furnishing. For others there is usually plenty of room among shrubs, and, really, Foxgloves never look better than when rising on the edge of a shrubbery, with the dark foliage behind as a setting. You need merely scatter the seeds at this time of year in the less-congested spots in order to obtain colonies, which afterwards will usually take care of themselves. Foxgloves, though biennials, do not die away after flowering, but if given good treatment they produce spikes 7 feet or 8 feet in height, with secondary ones of lesser altitudes, and if not allowed to produce seeds the same plant will live for several years. At the same time, young plants give the best results. I get nice effects with plants growing close to the base of walls. Foxglove is one of those names which have given unending trouble to philologists. On the Borders it used to be called Foxter, and in a copy of Fuchius' "Historia Plantarum" a MS. note has "Fox tre" for the Scots name. There are numerous other pretty names.

Thistles, as a rule, are not permitted much consideration by garden folk, but there are Thistles and Thistles, and a very handsome vegetable indeed is the Milk Thistle (*Silybum marianum*). In good soil it grows 6 feet in height and almost as much through, but one must take the precaution to sow the seed where the plant is to flower, as transplanting, if the plants grow at all, dwarfs them extremely. As well as possessing blotched foliage of much beauty, the flowers themselves are worth something. It is perhaps more adapted to the wild garden than to the kept parts of the grounds, but in any case high cultivation is imperative for the best results.

One of the prettiest of our native flowers is Succory, and though I do not advise the cultivation of this weed, I would like to say a word in favour of Endive, the flowers of which are essentially identical. They are of the same shade of colour as *Mulgedium rutenicum*, but the plants are of a superior habit and not at all coarse, as that is. As many plants as are wanted for the mixed border may be planted in autumn, or they may be wintered

in a frame, where they are not quite hardy, and planted out in April.

The Common Mullein, of which there is an improved variety, is a decorative plant not to be despised. It makes a desirable wall plant, but succeeds best near the base of the wall, though not necessarily growing in soil. Like some other biennials, it does best with the seeds sown where the plants are wanted to flower. The Mulleins are almost as well known under the generic name Verbascum. The genus includes effective border plants that produce stately flowering spikes from June to September. The Hoary Mullein, otherwise known as *V. pulverulentum*, is a striking plant,

A FINE SPECIMEN OF *PITOSPORUM EUGENIOIDES VARIEGATA* IN THE GARDENS AT TREBAH, CORNWALL.

the stems and leaves of which are covered with a mealy white wool. The flowers are produced in panicles of bright yellow. A remarkably effective plant for massing in wooded places is *Campanula latifolia*. It needs no cultivation, and the seeds may be scattered over the ground selected for them.

Rue gives us tones of colour quite distinct from those of any other plant. It is easy to grow from seeds. Fennel is also worth growing for its unique colouring, and selected forms of the whitish shades of foliage of Wormwood are equally distinct. Clary ought to be grown for a like reason, the silvery bracts being quite a feature.

R. P. BROTHERSTON

GARDENS OF TO-DAY.

TREBAH, CORNWALL.

TREBAH, the residence of C. H. Hext, Esq., is situated some six miles from the well-known and ancient town of Falmouth, the mansion standing in a prominent position at the top of a deep natural valley and looking down to that arm of the English Channel known as Helford Passage. The view from the front of the house, which is almost due south, is one of rare beauty, the valley, which forms the garden, being liberally yet tastefully clothed with subtropical vegetation, with a babbling stream and several miniature waterfalls running almost its entire length. Occasionally the patch of sea that is visible at the far end gives anchorage or fairway to some yacht or fishing-boat, and the whole surroundings have a peaceful, pleasant atmosphere such as we find in the Temperate House at Kew on a quiet day. Leading from the house to the valley or garden proper is a broad expanse of rolling greensward, on which light and shadow, caused by the surrounding trees, create a picture of enchanting beauty that would gladden the heart of the artist. The rather steep, sloping banks on either side of the valley are intersected with pathways, but so cleverly has the work been carried out that it is seldom one gets a glimpse of the paths, except in the immediate vicinity. Indeed, natural effect is aimed at throughout and successfully secured, harmony of colour and contour being a striking feature.

Rare Trees and Shrubs.—

In common with most other Cornish gardens, those at Trebah are rich in choice trees and shrubs. Rhododendrons and Bamboos finding a happy home in the lower regions of the valley. On the eastern slope we were interested to find a large tree of *Arancaria Bidwillii* and a beautiful specimen of *Podocarpus Totara*, the trunk of the latter measuring nearly five feet in circumference at the base. Near by are two fine examples of *Pinus insignis*, probably two of the best in the country; while *Embothrium coccineum*, the Japanese Umbrella Pine, *Sciadopitys verticillata*, *Acacia dealbata*, *Pittosporum eugenioides variegata* and *Drumys Winteri* all do well on this side of the garden. Indeed, there are so many good shrubs and trees to be seen there that it is impossible to do more than mention a few. On the western slope vegetation is equally interesting. Near the uppermost pathway we were interested to find a magnificent bush of *Coroeka macrocarpa* about ten feet high, a fine plant of *Crimodendron Hookeri*, a small but healthy plant of the rare *Olearia insignis*, *Desfontainea spmosa*, and a large tree, some twenty feet or more high, of *Banksia quercifolia*, which, at the time of our visit in mid-April, was bearing some of

its white, bottle-brush-like flowers. Near by was a truly magnificent bush of *Coronilla Emerus*, quite 20 feet in diameter, and just a mass of yellow, crimson marked flowers. Scrambling down a small grassy bank we found a fine plant of *Daphne indica*, the fragrant flowers of which we are only able to enjoy with the protection of a greenhouse. At the lower part of the valley the visitor suddenly comes upon an orchard, the grass of which is bejewelled with Primroses innumerable, to be followed later by myriads of Bluebells. Near this is a fine shrub of *Viburnum lucidum*, a great improvement on *V. Tinus* or *V. Laurustinus*, and keeping it company is a perfect specimen of *Cupressus macrocarpa*. This tree, which was planted when quite small by the head-gardener at Trebah, Mr. Thomas, is now quite 60 feet high, and the most beautiful of its kind we have ever seen. Nearer the mansion, and on the eastern slope, is *Hydrangea scandens*, which has climbed a Turkey Oak to a height of 30 feet and is still going on!

The Bamboos.—As already indicated, these form a prominent feature in the lower regions of the garden, and we saw some really remarkable specimens. One plant of *Bambusa (Phyllostachys) Quiloi* had stems 27 feet in height and over five inches in circumference, the plant itself at the base being about five feet in diameter. Mr. Thomas last year recorded the rate at which the canes of this Bamboo grew, and the particular cane that was under observation attained a height of 11 feet 10 inches in fourteen days, or nearly a foot a day! *Phyllostachys mitis*, with golden stems and paler golden foliage, and *Bambusa Falconeri*, 25 feet or more in height, were other plants that called for special mention, though there were many others of considerable interest.

Tree Ferns and Palms.—At the bottom of the lawn leading from the mansion, and slightly to the left, a trio of the beautiful New Zealand Tree Ferns, *Dicksonia antarctica*, create a pleasing and graceful picture, while in many parts of the gardens *Trachycarpus* or *Chamaerops excelsa* finds a happy home. Near a trickling stream we found a fine plant of *Phoenix canariensis*, a Palm that is not nearly so hardy as *Trachycarpus*, but which was quite happy in its surroundings. Many young Palms are being planted out, and in a few years' time will be quite a feature of the gardens. *Dracena indivisa* is also to be seen in many places, some of the plants having reached large dimensions. The New Zealand Flax, *Phormium tenax*, and its variegated form also thrive well in the lower parts of the garden, the huge clusters of sword-like foliage being perfectly in keeping with the surroundings.

The Water Garden.—This extends practically the whole length of the gardens, sometimes as a dancing rivulet, and anon as a placid pool wherein

Water Lilies, Cape Pondweed, Arum Lilies and many other choice water plants find a happy dwelling-place. On the banks of the rivulets such plants as *Primula japonica*, choice forms of Marsh Marigold, lusty plants of *Gunnera manicata* and many other kinds are planted with a lavish hand, yet always with a keen sense of refined taste and with a view to natural effect. At the time of our visit these water-side plants were just making new growth, and later in the summer would doubtless provide a floral picture of great beauty. On the western slope, and near the uppermost end, is a dainty little nook with a pool of crystal-like water, the banks of which are lined

A VIEW IN THE GARDENS AT TREBAH, LOOKING TOWARDS THE SEA.

with Ferns. Here we found *Woodwardia radicans* with fronds 10 feet long, so large, indeed, that it was difficult to recognise it as that species.

The Eastern Garden.—This is situated at the summit of the eastern slope of the valley, and is devoted to herbaceous and bulbous plants. Two of the most interesting plants that we found there were *Datura sulphurea* and *D. sanguinea*, both of which remain outdoors and flower all the winter. Over a little pergola at the end of this eastern garden *Clematis indivisa* was flinging its flower-bedecked shoots in profusion, happy in a climate that those who must garden in less-favoured districts would give much to secure.

THE ROSE GARDEN.

NEW DWARF AND CLIMBING POLYANTHA ROSES.

THE great value of this class as perpetual bloomers can be denied by none, but formerly we had scarcely any variety among the climbers that flowered more than once in the same season, or, if they did, the crop was so scanty as to be insignificant. Now, however, we seem fast approaching an ideal class of climbers that very much surpass

the Hybrid Wichuraianas, inasmuch as they possess a good deal of the same slender and graceful growths, together with the continuous blooming of our well-known dwarf Polyanthas so generally used for beds and edgings.

This is a want freely expressed at the International Conference of Roses held during the large and world-wide represented meeting in London last year. Herr Peter Lambert has recently given us several of these climbers, as well as quite a number of improved dwarfs. On glancing over a select list before me, I note he is responsible for no fewer than eighteen of our best varieties among the dwarf or bedding section, and is now sending out several that are excellent climbers, with the inestimable advantage of being continuous bloomers.

We have now a good climbing sport of Mrs. W. H. Cutbush which cannot fail to become a standing favourite, as it seems to retain all of the great floriferousness of that splendid pink bedder. Climbing *Cecile Brunner* and *White Pet* are other good sports; and if we can secure more reliable and fixed sports from other dwarf-growing Polyanthas, our arbours, pergolas and pillars will be greatly embellished. The greatest drawback at present is the dearth of bloom after the first summer or late spring glut. There is no lack of autumnal bloomers as dwarfs; indeed, it is here that we have so much advanced of late; but we do sadly want more flowers upon our climbers and pillars late in the season.

At the aforesaid Conference a very happy and irrite remark fell from Herr P. Lambert when he said we wanted to use Roses suitable for the purpose in the place of shrubs, which flower only ten to fourteen days in the year. So we do, and no one will be bold enough to dispute it. Not a few of our most charming Roses give us one good crop only, and, if we can improve such by continuation, the advance will indeed be great.

A few of the newer climbing Polyanthas that flower more or less continuously are *Excellenz Kunze*, creamy yellow and sulphur; *Frau Anna Pasquay*, dark carmine rose; *Graf Zeppelin*, deep coral red; *Jkyer D. Baronesse van Ittersum*,

scarlet crimson on orange ground; Kommerzienrat W. Rantenstrauch, salmon pink and yellow; Marie Treuz, rosy crimson; with Climbing Mrs. W. H. Cutbush. Some excellent dwarf growers are Backfisch, salmon pink; Boskoop Baby, China rose; Cyclope, crimson and maroon, striped white; Ellen Poulsen, brilliant pink; Erna Teschendorf, resembling the brilliancy of Grüss an Teplitz, really good; Unser Peti, peach and rose; with George Elger, coppery and golden yellow. A. P.

THE ROSE AS A BUTTON-HOLE FLOWER.

THE Rose as a button-hole flower is becoming more and more popular. The city man has taken up the cult, and it is very refreshing to note in the drab streets of our great cities how widespread the desire to grow a few Roses has become. A business man myself, who spends eleven hours daily in the city of Birmingham, I write for the guidance of men who, like myself, are fond of a Rose cut from one's own garden to wear for the day as a reminder of that home we, unfortunately, spend the greater part of our lives away from. Some Roses are not good stayers, even though the water in the holder may be changed once or twice during the day. Now as to varieties with good staying powers.

Pharisæer.—I cannot speak too highly of this variety. I have sometimes, when blooms were scarce, worn a flower of Pharisæer two days, and on the evening of the second day it was still presentable. A long bud, an ideal button-hole flower and a good grower. Colour, salmon pink.

Mme. Leon Pain.—Not quite such a stayer as Pharisæer, but, still, it will last out a hot day in a creditable manner. Colour, outside of petals deep pink, ivory white on the inside.

Prince de Bulgarie.—A grand Rose in every way. I have several bushes of this variety struck from cuttings inserted in the open ground in November. This Rose grows with equal vigour on its own roots as on the Briar stock. Colour variable. In early summer the blooms are pink in the centre, outer petals white; and in the autumn it often comes yellow, and is frequently mistaken for Joseph Hill.

Mme. Ravary.—This Rose I strongly recommend city men to grow. It is one of the most vigorous and one of the most sweetly scented. The delightful perfume is one of the greatest features it possesses. Its colour is a pleasing yellow, but it possesses one failing—it's grand colour does not last out the day.

Mrs. David McKee.—A reliable stayer. I have many times worn a good bloom two days, and it would still have done duty on the third if necessary. It is of a greenish white, perfect in shape, and with the scent of that grand Tea Rose Niphetos.

Mme. Constant Soupert.—A magnificent Tea Rose; yellow, tinted with pink. An excellent garden Rose, and quite ideal as a button-hole flower.

Dorothy Page-Roberts.—Coppery pink, shaded yellow. This Rose never fails to attract notice. Superb in colour and of great lasting powers, it holds its own in whatever company it may happen to be.

Sutton Coldfield.

J. W. H.

NOTES ON TULIPS.

IT was a great opportunity for the Tulip at Chelsea, and I think I may say it took advantage of it. In other words, most of the firms that make the sale of this flower one of their leading features staged groups of considerable size, and it was not their fault that they were not larger. To put my impressions in generalisations, I would say, first, that as the taste of the Tulip-lover is being "tuned up" he becomes more and more particular what he buys, and none but the best are now displayed to tempt him. Secondly, that that "rare bird," a novelty in staging, was to be seen in what I can only call the Tulip mountain of Messrs. Jefferies and Sons of Cirencester. I thought it a splendid idea, for it gives the arranger an opportunity of placing his flowers in the positions which suit them best. Thus, Ada (syn. Albion) and Sweetheart

out any wrong name and, if they are able, of substituting the proper one. Something of this sort is wanted with us. Fourthly, and lastly, more perhaps from conversations than from seeing them staged in large quantities, I fancy striped or broken Tulips are in the air. I was told that America was biting, and that if only our Yankee cousins had the sentimental side put before them they would be "landed." Messrs. Bath of Wisbech had, I think, the largest assortment in the whole exhibition.

The novelties in the twelve groups were provided for the most part by these broken varieties and the Darwins. Doubtless some of the Cottage would be unfamiliar to many, for Beauty of Bath, Hammer Hales, Gondvink, Lucifer, Mrs. W. O. Wolseley and Albion are not widely known as yet.

There is, of course, a great difference of opinion as to the relative merits of the different varieties. One thing the Tulip may justly claim is that it is

CAMPANULA STEVENSII NANA. A NEW VARIETY SHOWN AT CHELSEA LAST WEEK. (See page 275.)

(a rose Darwin with a wonderful pale blue base) are nothing above eye-level, while such a variety as Remembrance is best when seen only from the outside, and such should be above. Thirdly, I noticed a truly appalling amount of variation in nomenclature; just as sooner or later in its life-history every one-coloured flower, or breeder, as the florists express it, breaks and becomes parti-coloured, so it almost seems every variety may become many-named, e.g., Gala Beauty (syn. Columbus and French Crown) and Goliath (syn. Kingcourt and Cardinal Manning). This, to say the least, is very puzzling; but what is much more so is to find such labelling as putting Mrs. Moon on Leghorn Bonnet, White Queen on Parisian White, &c. I am told by Mr. Jan de Graaff, who is the chairman of the committee of judges of the Dutch Bulb Growers' Association, that at Haarlem the power is given them of crossing

as well able to cater for everyone's taste as any flower I know. In colour, habit, size and length of possible flowering season it "takes some beating." I would like to write on and on about its good points in the abstract and give concrete examples of what I mean, but my present purpose is not this, but rather to describe what I actually saw in the way of good things. I will begin with the Rembrandts (broken Darwins) and other broken varieties. The following little list includes some of the best: Admiral Kingsbergen, a tall, fine large crimson and white, vigorous and free; Victor Hugo (Rembrandt) a medium-sized bloom, well marked, scarlet and white; Bougainville (Rembrandt), a pleasing combination of purple and white; Quasimodo (Rembrandt), a striking and distinct shade of deep ruby red and white; Kroeschal, a magnificent combination of deep brick red or crimson and rich yellow, large flower and a vigorous grower;

Crimson Beauty, a dark rich crimson and white; and Procles, rather a small bloom, two shades of purple and white. If I were to add Semele (Rembrandt), rosy and white; Columbus, deep yellow and scarlet; Goldmine, orange brown and yellow in a curious and effective mixture; Union Jack, two shades of purple, or lilac and purple; Summer Beauty, rose, mauve and white; and the exquisite Zomerschoon, real pink and white, I think I could claim to have made out a list of some of the best.

JOSEPH JACOB.

(To be continued.)

MAINTAINING A LAWN IN GOOD CONDITION.

AS an under-greenkeeper at a first-class eighteen-hole golf course, my experiences may prove interesting and instructive. We are all aware that a good lawn is sure to arouse the admiration of all who see it, and to keep it in first-class condition a certain amount of expense and constant work are required. It is probable that no feature is more neglected than the lawn, yet, properly maintained, it can be termed the carpet of the garden. To have a fine rich herbage that glistens with its vivid green, imparts firmness yet elasticity to the tread, and grows in uniform evenness is to have perfection in a lawn; but to secure this it is essential that the ground upon which the lawn is constructed is well drained. It may already have sufficient natural drainage, and in that case nothing need be added; but where there is danger of the water not escaping within a reasonable time after a heavy downpour, then no expense should be spared in getting it drained properly; otherwise it will prove not only disappointing in appearance and unpleasant in its use, but the finer grasses will be smothered by overpowering moss. Apart from drainage, three of the chief operations that are essential in the maintenance of a lawn are exterminating worms, manuring and weeding.

Exterminating Worms.—In my opinion, worms are the worst enemies of lawns, for it is at the most critical period of the year that they begin their destructive work. What is the use of trying to attain a fine true and firm surface if these earth pests are allowed to exist? Lawns may be rolled incessantly week in and week out in order to attain a firm and clean surface, but serious damage will be done to the turf. Not only do worms deposit their casts upon the surface, but they are constantly disturbing the roots; therefore it is impossible for the grasses to knit together and grow in uniform evenness. As there are now quite a number of worm exterminators on the market, it is an easy matter to rid lawns of worms. The one that I can confidently recommend is the preparation supplied by Messrs. James Carter and Co. There is not the slightest danger of damaging the turf by its use. It should be used according to the makers' directions. A theory is advanced that worms may be regarded as beneficial to lawns by the casts which they deposit upon the surface, if these are brushed about. I quite agree with that point, because the casts are the best of the soil; but the question is, What is happening to the roots? It is like robbing Peter to pay Paul, and in my opinion it is far better to rid the lawn of worms and keep the good soil for the roots.

Manuring.—While good lawns are looked upon as ornaments, we must not forget that they are to

have a great deal of wear and tear upon them during the course of a year. It is, therefore, necessary that manuring should be done annually in order to maintain the fertility required to ensure a good growth of fine grasses. A compost consisting of good loamy soil, well-decayed manure and wood-ashes, applied in the early spring in a finely-sifted state evenly over the lawn to the depth of a quarter of an inch, and followed with a dressing of fertilising materials in the autumn, will help to maintain a lawn in good condition throughout the year. Many lawns are spoilt by being manured with unsuitable manures. Manures that are rich in phosphates and potash should be avoided, as they are apt to encourage Clovers and coarse weeds.

Weeding.—It will be impossible for lawns to develop a hard, close and uniform turf if they are infested with weeds. These not only rob the finer grasses of their food, but also of air, light and moisture. There are many preparations on the market now for killing weeds upon lawns, including sulphate of ammonia and various brands of lawn sand; but I am strongly in favour of hand-weeding, and I doubt whether any surer or cleaner method exists. It may seem a tedious operation, but I believe it to be the most economical.

Mowing and Rolling.—For the proper upkeep of a lawn, mowing must be frequent for at least six months in the year. Never allow the grass to grow long and ragged. In dry weather, and if the lawn is free from weeds, it is a good plan to forego the use of the grass-box, as the cuttings serve to protect the grass roots from the scorching sun; but should the lawn be weedy, it is not advisable to forego the grass-box, as the machine would scatter the weed seeds all over the lawn. Rolling should not be overdone, as it is ruinous to the turf. Some are under the impression that constantly rolling the lawn in the autumn will stop worms from working; but I think the tighter the surface, the more encouragement there will be for them to work. Our golf greens seldom have an iron roller upon them, yet they are as firm as a billiard table. In the absence of worms an occasional light rolling alone is necessary for the welfare of the lawn.

Elm Grove, Bishop's Stortford F. AUGER.

THE FRUIT GARDEN.

SEASONABLE NOTES ON GRAPE VINES.

AT no season of the year will cultivators find it necessary to pay closer attention to the Vines than the present. The growth is very rapid, both of bunches and shoots, and unless thinning out of berries and shoots—lateral growths—and judicious training are done just when they should be, the crop and the general condition of the Vines will not be satisfactory at the end of the season when all are ripened.

Training the Shoots.—These have a tendency to grow towards the light—the roof glass—from the first. They must be tied down, of course, but not all at one time, on account of their brittleness; tie them down gradually. When the berries have set, the shoots may be tied level with the wires, as they will be tough enough. Weakly and surplus shoots must be removed. Pinch off the ends of the shoots at two or three joints beyond the bunch retained, according to the space available, as all roof space should be nicely covered by the main leaves. Pinch off all secondary laterals from the

shoots beyond the first leaf. Thus will remain the shoot, the bunch of Grapes on it, the side or secondary shoots bearing one leaf only. Keep the Vines in this condition throughout the summer, pinching off every lateral shoot while very small.

When the Vines are in Flower.—The cultivator will soon be able to tell when they are in flower, as the scent is very sweet. Until all the berries are set it will be necessary to rather sharply tap the Vine rods about noon every day, especially while the sun is shining. Shy-setting varieties, such as the Muscats, should have a camel's-hair brush or a rabbit's tail lightly passed over them in addition to the shaking of the bunches by tapping the rods.

Watering and Feeding.—Vines do not make new roots in great quantities much before the month of May, and so it is not necessary nor advisable to saturate the borders too much with water so early in the season. Vines rooting in outside borders have had ample moisture; too much in badly-drained ones. Careful examination must be made to avoid too dry a condition of the soil. The first feeding with liquid manures should be given directly the berries have set. Before applying the manure give a copious watering with clear water.

Ventilation.—Air must be admitted freely on fine days. At ten o'clock every night open the ventilators 1 inch wide. Before the sun shines strongly on the glass the following morning increase the ventilation by opening the ventilators 2 inches; and by nine o'clock give ample ventilation. Decrease it from two o'clock in the afternoon, closing the ventilators entirely by half-past three o'clock, with plenty of atmospheric moisture, but do not syringe the leaves.

Vines in Greenhouses.—Sometimes cultivators fail to get satisfactory crops from Vines grown in greenhouses; others succeed. Much depends on the management, the situation of the house and the border in which the Vine roots are, and the immediate surroundings. I was once requested by a cultivator to come and see his greenhouse Vines, as he could grow no Grapes on them. I went, and as soon as I saw the house I told him he never would grow Grapes in it as at the time constructed. It was situated close to a high dwelling-house, in a partially-shaded spot, other tall buildings in close proximity causing still more shade, and, to complete a bad structure, shaded ribbed glass was used in the roof. The greenhouse Vine cannot be given the best treatment, but Black Hamburgs and Foster's Seedling, as well as Buckland Sweetwater, do very well as a rule. Other occupants of the house must be given first attention, perhaps. Well, the cultivator should not in any way shade the glass over the Vines. He must reduce ventilation on cold days and, above all, not have the door of the house propped open. So many do this. The ventilators should be ample for their purpose. An open door, week after week, will not conduce to the benefit of the plants in pots, and it will certainly be the means of causing a chill many times to the Vines and encourage mildew on the leaves. Usually there will be sufficient atmospheric moisture for the Vines through the necessary watering of the pot plants. Keep up the strength of the Vines by due attention to the border. If possible, wherever it may be placed, contrive to give liquid manures in due season. If outside, do not grow plants on it, nor place material on it that will prevent the sun's rays penetrating. If inside, and mainly under staging, keep the surface clean and sweet and open.

G. G.

GARDENING FOR BEGINNERS.

A SIMPLE BORDER FOR AUTUMN EFFECT.

DURING the late summer and early autumn days, flowers of good quality are none too plentiful in the herbaceous or mixed border. The scorching sun has then usually given the plants a severe check, and large, ugly gaps are too often present. A simple autumn border, and one that any beginner in gardening can plant at the present time, is composed of early-flowering or border Chrysanthemums, with a broad edging of some dwarf-growing annual. The accompanying illustration depicts a border of this kind, the edging in this instance being composed of *Alyssum Carpet White*. The Chrysanthemums used immediately behind the *Alyssum* are *Horace Martin*, which has good yellow flowers, and *Goacher's Crimson*, with blossoms of that colour and bronze. Coming behind these are taller plants of *Rubis*, an old and later-flowering variety with port-wine coloured blossoms. The green foliage of these formed a splendid background to the dwarfier varieties named, and as the latter remained in flower for about six weeks, the effect was most pleasing. These border Chrysanthemums may be purchased now in small pots, and if put out at once in good soil will quickly become established. When growing freely it is advisable to pinch out the point of each, as this induces a bushy habit. Watering during dry weather, frequent hoeing of the soil, and staking as and when required are practically all the attention that the plants require from now until flowering-time. Eighteen inches apart each way is a good distance to plant the dwarf varieties, but the taller ones should be given rather more room. Of course, many other varieties may be used in this way; but, for effect, only two or three sorts should be employed. The *Alyssum* can be purchased cheaply from any vendor of bedding plants, and should be put out 6 inches apart in a belt not less than 1 foot wide; a narrow edging is not nearly so effective or pleasing. If desired, dwarf Stocks, Asters or *Violas* could be utilised in place of the *Alyssum*, according to individual taste. These border Chrysanthemums, in addition to creating a beautiful floral display in the garden, provide a wealth of splendid flowers for cutting, in which condition they last good for a long time.

After the plants have finished flowering, the stems should be cut down nearly to the ground. If the soil is naturally damp and of a clayey nature, it is advisable to lift some of the best of the old stools, place them in large pots or boxes, with some soil made firm about their roots, and stand

them in a cold frame for the winter. Plants treated in this way provide excellent material for making cuttings the following spring. Where, however, the soil is light and warm, the plants will frequently stand well outdoors all the winter, their greatest enemy then being the slug. To prevent damage from this source, some coal-ashes and soot should be heaped up over the old stools,

in good time. Many less experienced in this matter defer the application of the mulch until the ground has become very dry, and the growth of the plants is arrested in consequence. The recent rains have well saturated the soil, and before the moisture is dried up from the surface portion some top-dressing material should be put on. The moisture is then conserved, also surface roots. Clayey as well as light soils should be dealt with. Leaf-soil and Coconut fibre are both suitable for use in the flower garden, and half-rotted manure for fruit and vegetables. Lawn grass may also be utilised for the same purpose. G. G.

A SIMPLE AUTUMN BORDER OF CHRYSANTHEMUMS EDGED WITH WHITE ALYSSUM. THESE CAN BE PLANTED NOW.

removing it when new growth is well advanced in the spring. But with choice varieties, and where there is any doubt about the plants surviving the winter outdoors, it is always advisable to lift a few and place them in cold frames as advised. Even there the depredations of slugs must be guarded against. H.

THE IMPORTANCE OF EARLY MULCHING.

The mulching of growing crops in both flower, fruit and vegetable gardens is generally carried out every year by experienced cultivators, and they are careful to apply the surface-dressings

THE RIGHT DISTANCE APART FOR BEDDING-OUT PLANTS.

The general effect of really fine specimens of bedding-out subjects is spoiled if they are overcrowded in the borders or put out too far apart. In the first case, the bushy habit of the plant soon changes and becomes drawn and weakly; in the second, owing to the short summer season, the plants do not fill up the space properly, thus leaving much surface soil visible between them. The quality of the soil must also be taken into consideration. Gross-growing subjects must not be planted in soil too rich, else there will be too much foliage and few flowers. Zonal *Pelargoniums* should only have a medium rich soil; *Nasturtiums*, a very poor soil. *Liliums*, *Zea japonica*, the *Castor Oil Plant* (*Ricinus Gibsonii*), the *Tobacco Plant*, the *Eucalyptus* and similar subjects intended to fill borders of a subtropical character should have a rich rooting medium. Plants with rich and variegated leaves must have a poor soil rather than rich. *Heliotropes*, *Begonias*, *Fuchsias* and *Petunias* require good soil. All these details must be taken into account when carrying out the work of planting, so that each specimen may make good progress and flower well, and nicely fill up the space in every bed.

A few hints on particular varieties may be useful as a guide. Zonal *Pelargoniums* should be put out 1 foot apart; *Heliotrope* and *Petunias*, 10 inches; *Fuchsias*, 18 inches; *Pansies*, 8 inches; *Calceolarias*, 10 inches; plants used as edgings, rather close at first; tuberous *Begonias*, 15 inches to 18 inches, according to the size of the tubers and strength of the plants in June; and fibrous-rooted *Begonias*, 9 inches or 10 inches asunder. Plants to form carpet-bed designs should be put out so that they almost touch each other at the time of planting. Dot plants must be disposed according to the character of the beds, and they must be seen clearly on every side. B.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Bedding-Out.—From the notes in last week's calendar it will naturally be inferred that bedding-out should proceed at once, as we should now be quite safe from frosts.

Manuring.—The beds, if manured in the autumn for the bulbs, should not require manuring again. They should, however, be deeply dug, working in a good dressing of soot and a little bone-meal before planting.

Watering.—It may be found after the bulbs are lifted that the beds are very dry, and a good soaking of water will be necessary to make the soil in a fit condition for the reception of the plants.

Planting.—Wherever possible, the hardiest plants, such as Zonals and Marguerites, should be planted first, leaving the more tender subjects, such as Begonias, Coleus, Iresines and Celosias, till the last. Where the soil is of a very light nature, the beds should not be raised to any extent, or there will be difficulty when watering has to be done; but it is sometimes an advantage to raise the beds considerably when the soil is of a good holding quality and inclined to lie wet. I have noted on many occasions the desultory manner in which many plants are put in the beds. Good firm planting, with the ball of soil well under the surface, is absolutely essential if the plants are to get over the check quickly and do well during the season, and any little extra trouble that is taken at planting-out-time is amply repaid, especially if we experience a dry season.

The Shrubberies.

Pruning.—Many flowering shrubs, such as Berberis, Lilac, Syringa and Deutzia, that have bloomed should now be cut back into shape a little, unless, of course, they are planted in such a position where they can be allowed unlimited growth.

Clematises.—These are now growing very rapidly, and must receive regular attention as to tying if the growth is to be kept at all within bounds, whether the plants are on the house, pergola, or up trees or stakes.

Plants Under Glass.

Perpetual-Flowering Carnations.—The earliest batch should now be ready for transferring into their flowering pots, and for such early plants 8½-inch pots are the most suitable size. A rich soil is not necessary, but it should be a good holding loam, with sufficient lightening material in it to keep it porous; thus plenty of road grit, lime rubble, broken crock and wood-ashes should be incorporated with it, and this is better than leaf-soil for Carnations, not forgetting a 4½-inch potful of bone-meal to each harrow-load of soil. Firm potting is also necessary to secure a sturdy growth, and from now onwards the plants may be stood out of doors on a good ash bottom, providing lights can be erected temporarily over them in the event of very wet weather.

Chrysanthemums.—Continue to pot Japanese varieties as the plants become fit. It is fatal to the plants' well-being if they are allowed to become badly pot-bound.

Cinerarias.—The main batch of Cinerarias may now be sown, selecting the varieties that are likely to prove most useful, both as regards their colour and habit of growth. Fine porous soil is the best to raise these plants in, and a quite cold, shady frame will produce much healthier plants than will a warmer structure.

Primulas.—The early-sown batch will be ready for pricking off, and a further batch of obconica and malacoides may be sown. These will make plants quite large enough for flowering in 4½-inch pots from January onwards.

The Kitchen Garden.

Frames from which Lettuces have been cut may be planted with Marrows or Ridge Cucumbers, or, if frame Cucumbers are required, these may be planted; and if the frame is given a lining of fresh manure, it should provide sufficient heat to give them a good start.

Carrots.—When the garden soil is of such a nature that Carrots do not do well in it, frames as previously mentioned may be utilised for the purpose, and good crops of Intermediate Carrots can be grown by sowing now. Also, in districts where it is difficult to raise good crops of Carrots owing to fly, an early June sowing will often succeed where earlier sowings have failed.

Marrows and Gourds may now be planted in the open ground, though if the garden is exposed to rough winds it is advisable to plant them in as sheltered a position as possible.

Fruits Under Glass.

Melons planted in frames early in the month will have made considerable growth, and as soon as the selected shoots have reached the sides of the frames they should be pinched, thus inducing lateral growths, from which a good set of fruit may be expected if proper attention is given to fertilisation.

Top-Dressing.—If sufficient soil was not put in the frame when planting, this should be added now in the form of a top-dressing, it being difficult to add later when a large number of lateral shoots have been made. Keep the collars of the plants fairly high, so that when watering they may remain dry, and a little dry lime sulphur or powdered charcoal sprinkled around the collars often prevents canker. A good supply of water during the growing season is quite necessary, and sufficient syringings must be given to keep down spider, but they need not be so frequent or as heavy as given to plants cultivated in houses. The best crops of Melons I have seen in frames have been where the lights were removed entirely in the middle of the day during the setting period.

Tomatoes also do well in frames from now onwards, and come in well after the early crops in the houses. Place the fruiting pots in the front of the frames, training the shoots a few inches from the glass from front to back, and by ventilating freely at the side (not top or bottom) a more even temperature is maintained and the fruit sets as freely as in the houses.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Sweet Peas.—The plants will now be growing freely, and continued attention must be given to the tying in of any shoots protruding beyond the sides of the stakes.

Planting Dahlias.—This work must now be proceeded with. It being understood that the ground was duly prepared, the stakes should first be driven in position, after which a small pit should be dug out at the side of the stake to receive the plant. It will be a great advantage if a special compost, light and rich, be made up and a good spadeful given to each plant. As the planting proceeds, each plant should be tied rather loosely to the stake.

Bedding-Out.—This work will still be proceeding, and I would remind readers that a few spare plants of all fragile plants should be planted in the reserve garden to fall back upon for filling up blanks in case of failure or accident.

Crown Imperials.—These showy spring flowers grow up with Mushroom-like rapidity and disappear as quickly. They sometimes develop seed-pods, and unless use is to be made of them, they should be picked off. It is the formation of seeds, not of flowers, that weakens a plant.

The Rock Garden.

Tidying Up.—Many of the plants have now finished flowering and are beginning to look unsightly. These should be cut over and all the weeds promptly removed.

Mesembryanthemum pugioniforme.—This is a rather striking plant, with fleshy triquetrous foliage and pale yellow flowers. I obtained a batch of cuttings of it from a South Devon garden, where it is said to be hardy. I root cuttings in the open in a seed-pan in September and winter them in a cold frame, planting them about the rockwork in May.

The Pleasure Grounds.

Watering.—We often have a spell of drought in June, when newly-planted trees and shrubs are apt to suffer unless attended to with water at the root.

Trimming Odd Corners.—It is no uncommon thing to see the lawns trimly kept, while in odd corners, where the mower cannot be applied, such as round trees, against buildings and in sharp angles, the grass is allowed to grow at will for weeks. This looks bad. Tidy with the scythe as far as possible, and a sharp knife deftly handed will do the rest.

Plants Under Glass.

Final Potting of Chrysanthemums.—This work cannot be delayed much longer. See that the pots and crocks are clean and dry, also have a good quantity of compost ready and put under cover, so that the work may proceed irrespective of weather conditions. Experienced growers have their individual theories as to soils, but we all know that success largely depends upon judicious feeding in the autumn. The following will, however, be found a good compost for general use: Turfy loam three parts, old Mushroom manure one part, half-decayed Beech or Oak leaves one part, sharp sand one part, bone-meal half a part, wood-ashes half a part, and about a six-inch potful of soot to four bushels of soil. If the plants are suffering for want of food, water in a pinch of Clay's or similar fertiliser prior to knocking the plant out of its present pot. Leave plenty of room for top-dressing.

Humea elegans.—Seeds of this graceful plant should now be sown in a cool frame.

Liquid Manure.—Many plants will now require help with liquid manure. The article can be had in many forms. Horse-manure with some soot put into a guano-bag and immersed in a tank of water will yield a safe stimulant. Good results will also be obtained by mixing guano or Clay's Fertilizer at the rate of 2oz. per gallon. Dissolve with a little hot water and then add cold water. Twice a week is quite often enough to apply liquid manure.

Fruits Under Glass.

Early Peaches.—Where the fruits are ripening, a net should be run along under the trees to catch the fruits which may fall. The Peach is easily damaged, and should be handled very carefully. All the fingers and thumb should be applied when picking the fruits.

Late Cucumbers.—Now that the frames are being cleared of bedding plants, a few lights may be profitably devoted to late Cucumbers. If seed has not been sown for this purpose, cuttings can be rooted in a few days.

The Hardy Fruit Garden.

Cleaning Strawberries.—The hoe should be run through all the Strawberry quarters, as fruits will be swelling now, and the less they are interfered with subsequently until the crop is picked the better.

Taking Strawberry Runners.—Where stock is wanted for early forcing, runners cannot be taken a day too soon. Fill rather more than the requisite number of 3-inch pots with light, rich soil, and sink a pot to its rim immediately under the young plant, securing the runner to the soil in the pot by means of a peg. Give all a watering when the layering is completed.

The Vegetable Garden.

Late Peas.—The last sowing for the season should be got in within the next week or ten days, and a second-early variety, such as Senator or The Pilot, is now preferable to a late variety.

Planting the Brassica Family.—Spring-sown Cabbages, Savoys, greens and Brussels Sprouts will now be ready for planting out, and showery weather is to be preferred for the work. From 21 inches to 24 inches by 18 inches is the correct distance apart for the foregoing. If the weather is really dry, make a puddle of earth and water and dip the roots in it prior to planting.

Asparagus-Beds will be benefited by a slight dressing with salt, preferably during showery weather.

Thinning Crops.—Beet, Turnips and Salsify should be thinned if not already done.

THE GREENHOUSE.

SEASONABLE NOTES ON AURICULAS.

Plants After Flowering.—One of the most common faults with amateurs and cottagers who cultivate these refined and altogether charming plants, and other kinds, too, as far as that goes, is to neglect them when they have finished flowering. Directly the blooms have gone the plants are forgotten until the end of the summer, or perhaps for a still longer period, and the natural result is that many of them die instead of living to produce more flowers in succeeding years. This is utterly wrong with any plants whose duration is more than one season, and particularly so with Auriculas, since some of the most important details of management come along after the period of floral beauty. It is then that one should consider the repotting and the removal of such enemies as the white aphid, which gathers round the crown of the plants, as well as other routine operations. Those who would achieve continued success with Auriculas must be prepared to have them in mind from one year's end to another, not because they will always be demanding attention or because they are "nuffy," but because any little thing that is required will be done at the correct time.

Choice of Pots.—The task of the moment is repotting, as June is the most generally satisfactory month for the operation. With many plants the precise shape of the pot does not matter much, provided that it affords proper space for the roots; but with Auriculas one should always give the preference to pots that are exceptionally deep in comparison with their diameter at the top. The plant forms a long tap root, and the ordinary pot does not give the depth which is demanded, or which is, if not really essential, beyond question most desirable. It is possible to procure these long, deep pots, though it is not always easy to find a supply; but the man who is determined to succeed will not begrudge the time necessary to provide for wants.

Repotting.—Having secured the most suitable and convenient pots, they must be washed, and, if new, allowed to drain before use. Then turn to the question of soil, and do not follow the old writers, who recommended the most extraordinary and weird mixtures. Sound loam of the finest quality should form the base and the bulk of the compost, and to it may be added at discretion thoroughly-rotted manure and sand or other opening material. Whatever the components may be, they ought to be put together several days before actual use. Opinions differ as to whether all the soil should be shaken off or not; but it has the material advantage of showing immediately if anything is amiss with the tap root, in which event it is promptly cut away, and also permits one to apply methylated spirit or other effective wash to destroy the white aphid.

When inspection reveals the fact that the fleshy tap root is in bad condition, necessitating cutting back to the healthy part, it will be wise to put the plant into a pot of the same size as that previously occupied, or, and sometimes wiser, into one a size smaller. This point will have to be decided upon the merits of each plant, and the governing factor will be the number of clean, sound roots. It is in no case desirable that the soil shall be rammed into the pots until it is as hard as a road; but it must not be, on the other hand, so loose that water applied will rush straight through to the drainage.

Find the happy medium between those extremes and the condition will be correct.

Considerable judgment will be required after potting in regard to the quantity of water. It is never wise to give much when the roots are not working freely, but it is imperative that the leaves shall not be permitted to flag seriously. To obviate the necessity for frequent applications, shade the frame from the fierce sun for a fortnight and do not admit quite as much fresh air. When there are unmistakable indications that the plants have fully recovered from the change of soil conditions, the normal amount of fresh air must be again provided to encourage satisfactory advance. Towards the end of the month frames which are facing the south should be turned to give them a northern, and therefore cooler, aspect.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

LILIUM CANDIDUM DISEASED (E. G. W.).—The white Lily is attacked by the Lily disease. It appears to have attacked the plant where it has been weakened, perhaps by frost or cold wind, or even by insect injury. No cure is known for this disease; but it would be worth while trying the effect of removing the top soil and replacing with fresh soil which has been well sterilised.

ASTERS AND WIREWORM (J. P.).—The grub eating your Asters is the wireworm. Picking out wireworms is the only remedy under the circumstances, but you may trap them by burying a half of a hollowed-out Potato in the soil near them. Sprinkling a little Aterite or Vaporate about the plants would also help to drive them away. Wireworms are one of the worst pests the gardener has to contend against.

ORCHIS (Collapit).—All the Orchids mentioned, except *Bletia hyacinthina* and *Calypso borealis*, would be suitable for growing in the grass unless it gets too thick and coarse. The roots must be planted quite 3 inches below the surface. *Habenaria bifolia*, *Ophrys apifera*, *O. lutea*, *O. speculum* and *Orchis provincialis* are lime-loving plants, and with *Habenaria ciliaris* are the best of those mentioned. In suitable situations they flower freely. *Bletia hyacinthina* and *Calypso borealis* require more careful treatment, especially the latter. They must be planted in a shady position in rich, leafy soil.

DIVIDING PRIMULA DENTICULATA (G. C.).—This *Primula* and all its forms is best raised periodically from seeds sown as soon as ripened. The divided example is rarely endowed with the vigour of the seedling, and seldom produces so good a growth. If divided, it should be done as soon as flowering is over. From a well-flowered plant, however, a couple of hundred seedlings might be raised, and with not much trouble. If the grass is not sufficiently dense to smother the plants, they may do well for a time, even in the gravelly soil, by reason of the moisture present. To avoid excess of flooding, give them somewhat raised positions where the root-fibres would reach moisture when necessary.

THE GREENHOUSE.

WHY PLACE PLANTS NEAR THE GLASS? (L. W.).—Curiously enough, the action of light is to retard the growth of plants, and the nearer they are to its presence the less are they likely to grow lanky. At the same time, a good supply of light enables them to obtain the power necessary to have in order to enable them to make their food, and for this cause, again, the nearer the source of light the better for them. No matter how good the glass may be, a certain amount of light is cut off by it, and

it is necessary for the plants to be as near to the source of light as possible. The placing of a second piece of glass over the plant would, therefore, not allow the plant to obtain the necessary light nor act in the same way as placing it near the glass.

CHRYSANTHEMUMS (E. F.).—The varieties you name would come under the heading of decorative varieties or early-flowering Japanese, though probably *Nina Blicke* might, if necessary, be shown as a reflexed; but we rarely see it classified as such nowadays. For blooming in the greenhouse later in the season you might grow the following: **Soleil d'Octobre*, **Bronze Soleil d'Octobre*, **La Triomphante* (pink), **Matthew Hodson* (chestnut), **Heston Bronze*, Dr. *Enguhard* (pink), **Freda Bedford* (bronze), **Moneymaker* (white), **Nagoya* (yellow), Mrs. *Andrew Walker* (coppery red), **December Gold* and **Baldeck's Crimson*. All the above are fairly close flowers, and about the shape of those you name. If you only wish to grow half-a-dozen varieties, you might choose those marked with an asterisk.

CULTURE OF CLIANTHUS (E. F. C.).—The culture of *Clanthus puniceus* and its variety *albus* differs according to the part of the country in which the plants are grown. In the milder parts of the country they thrive excellently against walls in the open, and good examples are met with in many parts of Cornwall and Devonshire. It is probable that you might be able to cultivate it against a wall with a south or west aspect, providing a small glass shelter could be attached to the top of the wall. Both plants are perennials, or, rather, sub-shrubs, and are raised from seeds. They thrive in well-drained loamy soil. In colder parts of the country they must be grown in a sunny greenhouse, either in pots or planted out in a well-drained border. As a rule, the best results are obtained by training them to pillars or rafters. *Clanthus Dampieri* is somewhat more tender than the last-named. It is usually treated as a biennial, sometimes as an annual. On its own roots it is a very difficult plant to grow; therefore it is usually grafted, while very young, upon stocks of the *Bladder Senna* (*Colutea arborescens*). Seeds of the *Colutea* are sown about a fortnight in advance of those of the *Clanthus*, and when the *Clanthus* seedlings are a few days old they are cut off 1 inch or so below the cotyledons. The stem is cut into the shape of a wedge by means of a sharp razor, and the stem of a young *Colutea* is slit down between the seed leaves, the wedge-shaped graft being inserted and secured in position with matting. The plants are then stood in a close, warm case for about a fortnight, after which time the union of stock and scion will be found to have taken place. The plants are then grown in an airy greenhouse and repotted when necessary, a compost being made up of two parts of fibrous loam to one part of peat or leaf-mould with a moderate amount of sand. When in flowering pots or baskets, manure-water may be given once a week when the soil is well filled with roots. It should have been mentioned that the *Colutea* seeds must be sown singly in small pots to avoid root disturbance.

ROSE GARDEN.

ROSE GROWTHS INJURED (C. T.).—The damage has been caused by caterpillars. You should have the trees well searched, and, if you have caterpillars, spray with arsenate of lead paste. The slugs can be kept down by using *Sluzene*. Both preparations are obtainable from Messrs. W. Voss and Co., Millwall, E. We think you would obtain all you require for your rock garden from any of the firms who advertise in our pages, and as they keep a large number of subjects in pots, they can be planted practically at any time.

PREPARING ROSE-BEDS (F. L. L.).—September would be about the best time to commence the preparation of the soil, and it would then be in a nice condition to plant towards the end of October, the best time of all for planting Roses. We do not advise chemical manures when preparing new beds, excepting basic slag and bone-meal. If you can procure a supply of really good farmyard manure in early September, you should do so; not strawy stuff, but good manure from a farm that has been well trodden over by horses, cattle and pigs. In preparing the soil it should be trenched, and any good gardener would show you how to have this done. The soil is moved to a depth of 2 feet to 3 feet; but the bottom, or subsoil, is kept in its place and not brought to the surface. With the lower soil we advocate mixing basic slag at the rate of about six ounces per square yard, together with a good layer of the farmyard manure. When the Roses are planted, give each plant a handful of bone-meal, mixing it with the soil at the time of planting.

FRUIT GARDEN.

BIRDS PICKING FRUIT-BUDS (W. S. R.).—Undoubtedly the moss on the trees attracted the birds in the first instance, this being, partially at least, the innocent cause of the fruit-buds being attacked. One way of preventing this in future will be by spraying your trees in winter with the caustic alkali wash. This will destroy every vestige of the moss, and clear the trees also of any other vegetable or parasitic insects by which they may be infested. This is a cheap wash, and may be had of any seed merchant advertising with us, with full particulars as to how to apply it. If you have any difficulty in procuring it, let us know, and we will give you the recipe. Where birds are numerous and fruit trees of the kind you mention not over-plentiful, buds are frequently destroyed. The only way of preventing the mischief is by netting the trees in good time.

MISCELLANEOUS.

DISEASE IN TOMATOES (*F. M. G.*).—From your description of the symptoms, we have no doubt whatever that the Tomatoes are attacked by a fungus, but in the absence of specimens it is impossible to say which one. We have no doubt the best method of avoiding the trouble is to steam sterilise the soil in which one intends to sow the seeds.

INSECT PESTS (*Edinburgh*).—1. We do not recognise the larvae sent with certainty. They are those of a moth belonging to the group called Noctue. It would have been a help to have mentioned the food plant. 2. The Rhododendron leaves have been bitten either by a weevil or by a caterpillar. The work of the two pests is very much alike. We would recommend you to spray the affected plants with lead arsenate, to be obtained in the paste form, mixed with water according to the directions supplied on the packet, and sprayed on with a very fine sprayer. 3. The slug trap advertised in our columns under the name of "V.T.H." will be found an excellent one. 4. The shade of Yews is too dense for most plants. You may find a few Ferns of the less exacting sorts will grow for a time in such a position, but they will require renewal now and again.

NAMES OF PLANTS.—*J. R. Dalton.*—*Cianthus Danjipori alba.*—*J. Brown.*—Rose Richmond.
E. M. H., Uffington.—1 and 2, *Helianthemum vulgare* variety; 3, *Saxifraga granulata*; 4, *S. hypnoides* variety; 5, *S. trifurcata*; 6, *Potentilla* species (very scrappy); 7, *Alyssum saxatile.*—*J. Thomas.*—The Bird Cherry (*Prunus Padus*).—*J. B., N. Wales.*—1, *Chrysosplenium oppositifolium* (Golden Saxifraga); 2, *Armeria maritima* (Thrift).—*E. W., Sheffield.*—Weevil Plant (*Cureliligo curvata*).—*T. H. R.*—1 and 6, *Helianthemum vulgare* variety; 2, *Tiarella cordifolia*; 3, *Geum hybridum*; 4, *Sedum altissimum*; 5, *Saxifraga Geum creatum*; 7 and 8, cannot name without flowers; 9, *Thymus vulgaris* variegatus; 10, *Iberis correaefolium.*—*W. L.*—1, *Acacia juniperina*; 2, *Sophora tetraptera microphylla.*

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY'S
SPRING SHOW AT CHELSEA.

SUNDRIES

(Continued from last week.)

Messrs. Corry and Co., Limited, Bedford Chambers, Covent Garden, W.C., had specimens of their tobacco preparations and insecticides, including syringes and other articles for which this firm is famous.

Paper flower-pots were shown by Messrs. Blake and Mackenzie, Liverpool.

A useful and interesting exhibit, including wire trainers of many forms, was staged by Mr. John Pinches, 3, Crown Buildings, Camberwell, S.E., bloom protectors and Acme labels being well to the fore.

Lawn boots of good workmanship and design were shown by Messrs. H. Pattison and Co., Greyhound Lane, Streatham.

Gishurst compound, fibre and insecticides were staged by Price's Patent Candle Company.

Weed-killers, lawn sand and insecticides were shown by the Acme Chemical Company, Tonbridge, and also examples of the Higginson patent spraying appliances.

Messrs. Robinson Brothers, Limited, Ryder's Green, West Bromwich, had a most interesting stand displaying Carmona fertiliser, with illustrated methods of application, Clift's fluid and pine spray, germinicides, insecticides and lawn sand.

Lawn-mowers suitable for all purposes were exhibited by Messrs. Alexander Shanks and Son, Bush Lane, E.C.

Messrs. Walter Voss and Co., Millwall, E.C., had a large and varied stand of the famous Carlton fertilisers, and examples of seedlings growing in sterilised and unsterilised soil.

The Abol syringe with its recent improvements now makes a perfect sprayer, and with Abol insecticide proved an attractive stand as shown by Messrs. E. A. White, Limited, Paddock Wood, Kent.

Messrs. James Carter and Co., Ravens Park, had a well-arranged stand, showing some large panoramic views of their other and seed-testing

station. Some excellent diagrams showing various seeds and their impurities were most instructive, and apparatus for simple analysis of soils for amateurs well deserved attention. A further interesting exhibit consisted of specimens of growing turf taken from twenty-two golf courses, which have been grown from their Tested Seeds, together with samples of soil from each course, one of the most interesting being turf from Merton course, grown from seed sown in November, 1912. A further interesting display was that of sections of the various seeds of Rape, Turnip, Black Mustard, Charlock and Cabbage, which in the seed are exactly similar. These diagrams were of great interest, showing the differential inter-cellular tissue of the sections, which were sufficiently distinct to enable one to distinguish one variety from another.

An interesting series of garden plans and designs were shown by Messrs. R. Wallace and Co., Colchester.

Messrs. Jeyes, Limited, Cannon Street, E.C., showed some good examples of insecticides and sprayers.

Messrs. Joseph Bentley, Limited, Barrow-on-Humber, had a well-arranged stand of weed-killers and other horticultural chemical specialities.

Mr. G. Dunford, 11, Ley Road, Ilford, showed his well-known lawn brooms.

The French Cloche Company, Caxton House, Westminster, staged specimens of cloches, mats and frames, and all other requisites for French gardening.

Messrs. Thomas Green and Sons, New Surrey Works, S.E., had a well-displayed assortment of lawn mowers in all sizes, and garden rollers. A motor lawn mower of improved form was also exhibited.

Mr. Vernon T. Hill, Langford, near Bristol, staged his patent slug trap.

The Key fertilisers were shown by Mr. A. Key, The Crescent, Norwich.

Messrs. Ransomes, Sims and Jerreries, Ipswich, had an attractive exhibit of motor, horse and hand power lawn-mowers, suitable for all purposes.

Robert Sydenham, Limited, Birmingham, showed rustic table decorations in many pretty and attractive designs.

Steel garden stakes and hoops for fastening were shown by Messrs. F. Walters and Co., Bilton, Rugby.

A large and varied exhibit of garden requisites was staged by Messrs. Barr and Sons, King Street, Covent Garden, including garden labels, patent bulb planter and dibber, and artificial manures of every description.

MEDALS AND CUPS AWARDED.

GOLD MEDALS.—Sir George Holford, K.C.V.O., Cl E., Westonbirt, Tetbury, Messrs. Charlesworth and Co., Hayward's Heath, and Messrs. Sander and Sons, St. Albans, for Orchids; Messrs. R. Wallace and Co., Colchester, for rock and formal garden; Mr. J. Wood, Boston Spa, for rock garden; Messrs. James Carter and Co., Raynes Park, for flowering plants and vegetables; Messrs. Veitch and Sons, Chelsea, for trained fruit trees and stove, greenhouse and flowering plants; Messrs. Sutton and Sons, Reading, for flowering plants; Mr. E. R. Russell, Richmond, for stove plants and shrubs; Messrs. Blackmore and Langdon, Bath, for Begonias, &c.; Messrs. Frank Cant and Co., Colchester, for Roses; Messrs. R. and G. Outbrett, Highgate, for Azaleas; Messrs. Dobbie and Co., Edinburgh, for Sweet Peas, &c.; Mr. C. Engelmann, Saffron Walden, for Carnations; Messrs. W. Paul and Sons, Waltham Cross, for Roses and flowering plants; Messrs. J. Piper and Sons, Bayswater, for shrubs, &c.; Messrs. J. Waterer and Sons, Bagshot, for flowering plants; Messrs. H. B. May and Sons, Edmonton, for Ferns; Messrs. Alex. Dickson, Newtownards, for Tulips; the Hon. Vicary Gibbs, Elstree, for vegetables; Messrs. W. Frowen and Sons, Chuswick, for Japanese Maples; Messrs. T. Rivers and Son, Sawbridge-worth, for fruit trees and Citrus fruits in pots; and Messrs. W. Cutbush and Son, Highgate Nurseries, for Carnations.

FARRER CUP.—Messrs. Bees, Limited, Liverpool, for alpinas.

DAVIDSON CUP.—Messrs. Charlesworth, Hayward's Heath, for the best Cattleya, not a hybrid, in the show, *C. percivaliana* Mary Regina.

SILVER-GILT CUPS.—Messrs. J. Backhouse and Son, Limited, York; Messrs. Barr and Sons, Covent Garden; and Messrs. J. Piper and Son, Bayswater, W., for rock and water gardens; Messrs. J. Veitch and Sons, Chelsea, for Tulips and general exhibits; Messrs. Jackman and Sons, Woking, for Clematises, shrubs and plants; Messrs. G. Bunyard and Co., Maidstone, for Apples, and Messrs. Wallace and Co., Colchester, for a herbaceous group.

LARGE SILVER CUPS.—Mr. Maurice Pritchard, Christchurch, for alpine garden and herbaceous plants; Messrs. Sutton and Sons, Reading, for vegetables, &c.; Mr. E. R. Russell, Richmond, for foliage and flowering plants; Messrs. G. Paul and Sons, Chessington, for Roses and Azaleas; Mr. Charles Turner, Slough, for Roses, Carnations, Lilies, &c.; Messrs. E. Webb and Sons, Stourbridge, for Calceolarias and flowering plants; Messrs. Young and Co., Cheltenham, for Carnations; Mr. Amos Perry, Enfield, for herbaceous plants and alpinas; Mr. A. Dutton, Ivry, for Carnations; and Messrs. John Peed and Son, West Norwood, for Caladinias, &c.

SILVER CUPS.—Sir Jeremiah Colman, Bart., Gatton Park, Reigate, Messrs. Armstrong and Brown, Tunbridge Wells, Messrs. J. Cypher and Sons, Cheltenham, Messrs. Stuart Low and Co., Bush Hill Park, and Messrs. J. and A. McBean, Cooksbridge, for Orchids; Messrs. Pinham and Son, Newman Street, for Orchids; Messrs. T. S. Ware, Limited, Feltham, for rock gardens; Messrs. J. Cheal and Sons, Crawley, for formal garden and alpinas and shrubs; Messrs. James Carter and Co., High Holborn, for formal garden; the Hon. Vicary Gibbs, Elstree, and Miss Troyte-Bullock, Yeovil, for Pelargoniums; Leopold de Rothschild, Esq., C.V.O., Loughton Buzzard, for Carnations and Statice; Messrs. W. Cutbush, Highgate, for flowering plants; Messrs. B. R. Cant, Colchester, for Roses; Messrs. J. Hill and Son, Lower Edmonton, for Ferns; Messrs. Hobbies, Limited, Dereham, for Roses; Mr. J. Macdonald, Harpenden, for Grasses; and Messrs. G. Mount and Sons, Canterbury, for Roses.

STANDARD CUPS.—E. H. Davidson, Esq., Borlases, Twyford, and Messrs. Mansell and Hatcher, Rawdon, for Orchids; The Craven Nursery Company, Clapham, Yorks, for rock garden; Messrs. Cunningham, Fraser and Co., Edinburgh, for alpine plants; Mr. Clarence Elliott, Six Hills Nursery, Stevenage, for rock garden; Mr. G. Renthle, Keston, for rock garden and herbaceous plants; Messrs. Whitelegg and Page, Chislehurst, for rock garden and alpinas; Messrs. G. Beckwith and Sons, Hoddson, for Roses; Mrs. B. Barrett, Castlethorpe, for Schizanthus; Mr. A. J. Bruce, Chorlton-cum-Hardy, for Sarracenas; Mr. Reginald Pritchard, Wimborne, for alpinas; Mr. George Prince, Longworth, for Roses; Dr. John Macwatt, Duns, for Primulas; and Mrs. Litkie, Maidenhead, for herbaceous plants.

SILVER-GILT HOGG MEDAL.—Messrs. Laxton Brothers, Bedford, for Strawberries and fruit trees.

SILVER-GILT KNIGHTIAN MEDAL.—The King's Acro Nurseries, Hereford, for fruit trees.

SILVER-GILT FLORA MEDALS.—Messrs. Hassall and Co., Southgate, for Orchids; Messrs. Barr and Son, Covent Garden, for Tulips, &c.; Messrs. Stuart Low, Bush Hill Park, for Carnations, &c.; Messrs. Phillips and Taylor, Bracknell, for herbaceous plants; Messrs. Hogg and Robertson, Dublin, for Tulips, &c.; Mr. Bell, Guernsey, for Carnations; Mr. Box, Lindfield, for hardy plants; Mr. Burnett, Guernsey, for Carnations; Messrs. Clark, Dover, for herbaceous plants; Messrs. Jefferies, Cirencester, for Tulips; and Messrs. Ware, Feltham, for herbaceous plants.

SILVER-GILT BANKSIAN MEDALS.—The Guildford Hardy Plant Nursery, Guildford, for rock garden; Messrs. Artindale, Sheffield, for hardy and water plants; Messrs. Allwood, Hayward's Heath, for Carnations; Baker's, Wolverhampton, for hardy alpine and bog plants; Messrs. Fletcher, Chertsey, for American plants; Messrs. Gibson, Bedale, and Messrs. Kelway, Langport, for herbaceous plants; Messrs. Ker, Liverpool, for Amaryllis; Messrs. Needham, Kilmacott, for Tulips; Messrs. Notcutt, Woolbridge, for flowering and foliage plants; and Messrs. Watkins and Simpson, Covent Garden, for annuals in pots.

SILVER KNIGHTIAN MEDAL.—Thatcham Fruit Farm, Newbury, for vegetables.

SILVER FLORA MEDALS.—Mr. S. W. Flory, Twickenham, for Orchids; The Burton Hardy Plant Nurseries, Christchurch, for rock garden; Messrs. Bath, Wisbech, for Tulips and Carnations; Mr. C. Bliok, Hayes, for Carnations; Mr. C. Bourne, Bletchley, for Tulips; A. P. Brandt, Esq., Bletchingley, for fancy Pelargoniums; Messrs. Cannell, Swanley, for Cannas, Pelargoniums, &c.; Messrs. Carter Page, London Wall, for herbaceous plants and annuals; Mr. Douglas, Great Bookham, for Carnations; Mrs. Edwards, Langdon, for alpinas; Messrs. Godfrey, Exmouth, for Pelargoniums, &c.; Messrs. Gunn, Olton, for herbaceous plants; Mr. Hemsley, Crawley, for alpinas; The Misses Hopkins, Shepperton, for herbaceous plants; Messrs. E. W. King and Co., Coggeshall, for Sweet Peas; the Rev. H. Buckton, Hutton Hall, for Calceolarias; Mrs. Rolls Hoare, Horsham, for scented Pelargoniums; Robert Sydenham, Limited, Birmingham, for Sweet Peas; Messrs. Thomson and Sherman, Adelphi, for hardy plants; Messrs. Robert Veitch, Exeter, for Calceolarias; The Wargrave Plant Farm, Liverpool Street, E.C., for Tulips and herbaceous plants; and Messrs. Carlton White, Bond Street, for clipped Box and topiary work.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Our Art Supplement.—In response to requests made by numerous readers on different occasions, we are presenting with this issue a photographic art supplement in place of the usual coloured plate. Other supplements of this kind will appear in our issues for July 5, August 2 and August 30 respectively, after which date a coloured plate will appear every fortnight as usual. In the meantime coloured plates will be presented with our issues dated June 21, July 19 and August 16.

Effective Combination Under Deciduous Trees.—A very pleasing effect may be obtained by planting *Thaspium aureum*, the North American Meadow Parsnip, which has yellow leaves and flowers somewhat resembling a hardy *Euphorbia*, with the common Bluebell, both requiring the amount of shade obtained by the trees. The *Thaspium* is easily increased by divisions or by seed, and soon becomes established. The plants then give an attractive display of beauty annually.

Asters and Insects.—Now that thousands of Asters are being planted out for summer effect, we would warn readers of the danger that is usually lurking unseen among them. Too often we hear complaints of plants with their young foliage curled and crippled, and this is usually due to mites or aphides. As each plant is lifted from the box, it should be dipped into some weak insecticide and moved about in it, so as to thoroughly wet the whole of the foliage. This simple task now will in many cases mean the difference between success and failure later on.

A Useful Crevice Plant (*Erinus alpinus*).—Of the multiplicity of alpinæ that flower at this season, *Erinus alpinus* occupies a foremost position, particularly as a subject that finds a suitable home in chinks in the alpine garden. Moreover, it is an excellent wall plant, and may easily be established in a wall by sowing seeds in crevices that have been filled in with a stony or gritty peat and loam. *E. alpinus* has variable rosy purple flowers, and the variety *albus* is a white counterpart. It is a native of the mountains of Western Europe, but it is naturalised here and there in Britain.

An Iris for the Water-side.—*Iris sibirica* can be depended upon to grow and flower freely if planted about the margins of lakes, ponds or streams where the roots are continually moist, and there are few shower subjects when it is at its best during early June. Throughout the growing season the grass-like leaves present a pleasing change from coarser vegetation, whereas the tall, slender flower-scapes, growing to a height of 2½ feet or 3 feet, terminated with lilac purple or bluish flowers, are most attractive. Added to this, it gives comparatively little trouble, for, once established, it grows for several years without attention other than keeping it clear of coarse weeds. When the clumps become overgrown they are

easily put right by dividing up into smaller sections as soon as the flowers fade.

Wild Gorse and Broom.—Never before in the memory of the oldest inhabitants of the Southern Counties have the hillsides and commons been so resplendent with Gorse and Broom as they are this year. The Gorse in particular has been wonderfully effective, the large, irregular masses of dark green and gold providing an object-lesson in landscape effect that gardeners would do well to make a mental note of. Both plants thrive admirably on dry, sandy soil where little else will grow, a fact that is now being taken advantage of in gardens where soil of this character exists, the double-flowered Gorse and *Cytisus scoparius andreanus* being extensively planted.

The European Snowy Mespilus.—In *Amelanchier vulgaris*, a native of Europe, we possess one of the best Snowy Mespilus or June-berries for small gardens. It forms a spreading bush averaging 3 feet to 6 feet high, and, being comparatively slow in growth, does not outgrow its position a few years after planting. A vulgaris is later in flowering than the better-known *A. canadensis*, being at its best at the beginning of May, and the flowers are not so fleeting as those of that species. *A. vulgaris* is readily distinguished from all the other species by its bushy habit, hairy leaves and large, pure white flowers. The *Amelanchiers* thrive in most soils and situations. Seeds and layering form ready means of increase.

The Fuchsia-flowered Gooseberry.—*Ribes speciosum*, sometimes known as *R. fuchsioides*, the Fuchsia Gooseberry of California, is one of the most interesting of the flowering shrubs blooming at the present time. The elegant sprays of flowers, which are borne in clusters of one to three, with the stamens twice as long as the calyces, are of a rich deep red, and somewhat resemble the Fuchsia. They are very attractive, being borne on the previous year's growth from 3 feet to 4 feet long. If room permits, it may be allowed to grow naturally—it will then form a bush from 6 feet to 8 feet high; but if the space for it is limited, it should be cut back as soon as the flowers are over. In either case it produces a very pleasing effect.

A Beautiful Hardy Annual.—One of the most interesting annual plants that we have in flower outdoors just now is *Collomia coccinea*, which, although a native of Chili, stands our winters unharmed. The plants we have were self-sown last autumn, and have now made dense little bushes some 12 inches to 15 inches high. The flowers, which are vermilion in colour, are produced in rather dense clusters, much in the same way as those of *Crassula* or *Rochea falcata*. The under surface of the petals, and also the flower-tube, is of rich apricot hue. In addition to its value for the outdoor garden, this annual is excellent for growing in pots in the greenhouse, where it will flower early in the year. It is difficult to understand why it is so little known.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Why not a Hardy Shrub Society?—We have now Rose, Sweet Pea, Hardy Plant, Auricula and other societies for the study and popularisation of various species of plant-life. May I ask, why not a Hardy Shrub Society? There is a large and growing interest in the beautiful flowering and evergreen shrubs which we can grow in the open in these islands, and their number is being added to yearly. A society which would promote the planting of the best of these in private gardens and might assist their appropriate use in public gardens and parks should be of value to all garden-lovers. If some of the leading growers of hardy shrubs would take up this idea, the writer, as a humble amateur, would be glad to give any assistance in his power.—E. A. CROFT.

Cutting the Foliage of Bulbs.

Those who grow Darwin and Cottage Tulips largely are, naturally, much interested in the question of cutting back after flowering. Owing to the fierce spell of summer weather which set in just after the Chelsea Show, the flowers aged rapidly and, moreover, the foliage ripened with a rapidity that I have never seen equalled. To my mind it is simply bad gardening to let long stems and masses of textureless leaves remain on the plants for many days and even weeks—an eyesore in the garden and absolutely without benefit to the bulbs. The fear of premature leaf removal sends people to extremes. Let them boldly cut the flower-stems away quite low, with the small, thin, waning leaves adhering, but keep the large feeder leaf near the base as long as possible. The appearance of the garden generally will benefit immensely, and the bulbs will not suffer injury one jot. New bulbs form every year, and I recently turned some up that were large and well coloured. I may add that it is a complete delusion to suppose that May Tulips require annual removal.—W. P. W.

Exterminating Worms.—I was rather surprised to see no editorial comment on Mr. F. Auger's remarks on exterminating worms in lawns that appeared on page 280 of last week's issue. Worms, instead of being the "worst enemies" of lawns, are their best and, indeed, their indispensable friends. They do absolutely no injury whatever to the grass roots, and the necessary aeration of the soil is almost wholly their work. The foolish folk who waste money on the advertised worm destroyers and attempt to entirely banish worms from their grass would succeed in nothing but rendering the soil inert, dead and incapable of growing grass at all. Fortunately, it is probably

an impossibility to really exterminate the worms on a grass plot of any size. The only place where worms are hurtful is a pot or seed-pan, where the poor creatures are imprisoned and unable to live naturally.—G. H. ENGLEHEART. [We publish Mr. Engleheart's letter, but cannot agree with all his statements. Although worms may not injure the roots of the grasses, their casts are a great nuisance, as many owners of lawns know to their cost.—ED.]

Climbers for a Lofty Conservatory.—On reading an answer entitled "Climbers in a Lofty Conservatory" in THE GARDEN, issue May 24,

An excellent way of covering a shady wall in a conservatory is with the common Hart's-tongue Fern, planted in shallow soil, covered with moss, the latter being kept in place on the wall by means of narrow strands of iron. The entire surface of a large wall—if in the shade—may be beautified in this manner.—ELEANOR SHELLEY, *Avington, Alresford, Hants.*

A Beautiful Hybrid Primula.—I send with this note a spike of a hybrid Primula which my gardener, Mr. William Robertson, has been successful in rearing. It is a cross between *P. bulleyana* and *P. beesiana*. It received a first-class certificate last year from the Scottish Horticultural Society. This year the plants have thriven well and have flowered, as I think, with exceptional beauty. I hope you will agree with me when you see the flowering stem which I send with this. The Primula measures now from the ground to the top 27½ inches, and should grow at least 1 inch or 2 inches more. The whorls have seventeen or eighteen flowers on each. The colour, as you will see if the spike travels at all well, combines the purple red of *P. beesiana* with the apricot of *P. bulleyana* very delightfully. It has a perfume, which it takes from the pollen parent, *P. bulleyana*. The hybrid is named *Leddy Pilrig*.—(Miss) B. BALFOUR-MELVILLE. [The Primula sent by Miss Balfour-Melville is one of the prettiest we have ever seen. The spike had seven whorls of flowers, the sturdy stem and calyces being coated with farina.—ED.]

A BEAUTIFUL NEW HYBRID PRIMULA, LEDDY PILRIG, THE RESULT OF CROSSING *P. BULLEYANA* AND *P. BEESIANA*.

page XVI, the following additional climbing plants, with their varieties, occur to me, all of which flourish here without stove heat: *Abutilon*, practically evergreen; *Taesoma*, seen to advantage on a roof, from which it hangs in long, graceful sprays, and very quick growing; *Bougainvillea*, *Plumbago*, the species of *Fuchsia* (*F. gracilis* I think it is) with all red flowers on long, slender stalks and large, handsome leaves; also *Vitis henryana*, the distinctively marked leaves of which are most effective trained up a pillar. It turns a deep crimson purple in winter and is self-clinging.

Lettuces were grown on rubbish soils collected during the summer and winter from the potting-sheds and other places, and, being mixed with leaf-soil, were put down 1 foot to 18 inches deep on mild hot-beds in the open in early spring. Boards on edge, with Pea-sticks or laths on the top to support clean litter or canvas on frosty nights, constituted all the protection needed, and really very fine crops were secured many weeks before they could be had from the open borders. The present is a good time to commence collecting odd soils for the purpose.—AVON.

A Charming Wallflower.—*Cheiranthus Allioni* showed up prettily in one or two of the rock gardens at the Chelsea Show, Messrs. Barr and Sons having a particularly bright patch of it. Those who admire this cheery little Wallflower should grow also *C. Arkwrightii*, that is, if it is procurable, and I have an idea that it is now on the market. This plant is a cross between *Allioni* and *alpinus*, and was raised by Mr. J. S. Arkwright of Presteign. Plants sent me by the raiser a year or two back are now in full flower here, and are among the brightest little pieces of colour in my garden.—**F. HERBERT CHAPMAN, Rye.**

Davidia involucrata.—This must be a wonderful tree, by all accounts, when in bloom. Although now, I suppose, found in several gardens, it must be still quite uncommon. I bought a very small plant of it from Messrs. Lemome, Nancy, in December, 1906. It came by post in a tiny box. The plant could not have been more than a few inches in length. Now it measures 5 feet 2 inches in height, and is exactly 4 inches in circumference at the thickest part of the stem. The singularity of the tree, and its strange beauty when in flower, would almost seem to make a journey to China worth while to see it in its home! How much we owe to the enterprise of Messrs. Veitch and Mr. Wilson! They have placed within our reach such a large number of beautiful Chinese plants and trees.—(Rev.) WILLIAM W. FLEMING, *Coolfin, Portlao, County Waterford.*

Honesty in the Wild Garden. I am much interested in the reference to the above-named plant in "Notes of the Week," issue May 24, and also on page 276, May 31 issue. The general beauty and usefulness of the plant is not recognised as much as it deserves to be. As suggested in the notes referred to, the best place for the plants is the wild or semi-cultivated portion of the garden. The seedlings are tenacious of life, and will survive in most unlikely places. In a garden in Lancashire there is a wild portion of great extent; in fact, it encircles a small park, and has a wide strip (varying in width) of ground in which trees, shrubs, bulbous and other kinds of plants, including *Honesty*, grow. The latter formed irregular masses and looked charming indeed when in flower, and when the seed-shields were mature the plants were cut down and the shields gently beaten to separate them.—**B.**

Toads in the Garden.—Perhaps I may be allowed space to make another brief reference to the value of toads in the garden. "H. P." has a very interesting note on page 251, issue May 24. Many years ago I was told by a gardener, who for a time worked in Messrs. Dicksons', Limited, nursery at Chester, that there was a toad kept in one of the propagating-houses, and that he was greatly valued and made quite a pet of. He had lost one eye. At stated times he used to take his stroll, hop, or walk far out into the nursery grounds; but, with equal punctuality, he was back at the door of the house waiting for the attendant to come and open it, when he would go in. This toad was a very old one. I have found toads invaluable in vineries and houses where earwigs, woodlice and other insect pests were troublesome. The two I had last I accidentally killed through sprinkling an insecticide powder on them behind the hot-water pipes.—**G. G.**

Rose Lady Hillingdon.—My experience of this Rose is quite in opposition to the note on page 225, May 10 issue, in which doubt is cast upon the good manners of this charming variety in the open. My plant of it was put out in June, 1911, from a

pot, when it gave some nice blooms quite late in the autumn. Last year, in spite of the bad season, especially in our stiff soil with so much rain, I had a lovely lot of intensely-coloured flowers. The only fault I find with its growth is that the stems and peduncles are weak. This, coupled with the weight of the full flowers, makes them droop. In this way the blooms do not show themselves so well upon the plants or in a cut state; except for the latter purpose they are neatly wired.—**E. M.** [The drooping habit of this Rose is undoubtedly a great drawback, but this could be tolerated if the colour were good. We have never seen blooms of really good colour from outdoor bushes in a fully-exposed situation.—**ED.**]

Primula cockburniana.—It is a pleasure to receive the experience of so many of your readers with *P. cockburniana*, but I am rather surprised to observe that several of them appear to attach little importance to the biennial or perennial habit of this *Primula*. If we are to look upon it as a really reliable occupant of our gardens, we must endeavour to secure its cultivation as a perennial and not as a biennial. One knows how many really good biennials are dropped out of gardens because they either do not sow themselves well or require renewal, either by saving seeds or by propagation, by division, or cuttings. *P. cockburniana* does sow itself well in many places, but in others it has hardly any opportunity of doing so, and cannot be trusted to be left alone to reproduce itself. In such places, at least, it is highly desirable, surely, that it should be grown as a perennial. The multiplicity of plants which require constant propagation is quite a strain upon the resources of many places, without adding any more than can be helped. If, however, it can be proved to satisfaction that old plants are inferior to young ones, a sufficient reason for annual propagation from seeds and treating *P. cockburniana* as a biennial might be admitted. I am confident, however, that any who have an opportunity of seeing the old plants as grown by Mr. W. Hutchinson in the gardens of Mr. C. E. Galbraith at Terregles, Dumfries, will not be disposed to favour growing *P. cockburniana* as a biennial. The picture of health, free-blooming and beautiful, these plants, as I saw them a week or so ago, were superb, and much superior to small one year old plants, however well grown. We find that new plants receive more attention in the way of propagation than old ones; and that they may receive some new claimant for the limited amount of time at the disposal of the garden calls for attention in the way of propagation. But for the necessity of frequent propagation, the old double Rockets and the Mule Punks, for example, would be all the more cultivated instead of being comparatively scarce now. *P. cockburniana* has the advantage over these of reproducing itself from seeds, but it should be the aim of all to have as few things as possible to raise annually, unless there are gains commensurate with the amount of time and trouble they require. Those of us who know the pressure of work in many gardens always welcome any knowledge of cultural detail which will keep it as low as possible.—**S. ARNOTT.**

FORTHCOMING EVENTS.

June 11.—East Angham Horticultural Club's Meeting.

June 13.—National Hardy Plant Society's Show at the Royal Horticultural Society's Hall.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

USUALLY, cultivators possess batches of plants for exhibition—for the production of large blooms in a cut state to place on boards or in vases—as specimens, for the furnishing of the conservatory or greenhouse, and for the supply of cut flowers from the time of Dahlias to Christmas and after. These are in addition to the plants grown in the open borders. All these require a vast amount of attention and labour if they are to be quite satisfactory in due season. Many persons have ample space outside to accommodate the plants in the summer, but lack it under glass in the autumn. It is a mistake to over-stock, and this is the time to make the balance.

Potting. Throughout the month of June, growers will be busy potting some of their plants, notably those late-rooted which are being transferred to their flowering pots. Very hard ramming down of the soil must be avoided. An experienced cultivator, who is now growing a batch of plants in earnest, called on me a few days ago and asked me to give him a few hints about composts and potting. He said: "I have grown a few plants in previous years, but without much success; I think I pot too hard, and take quite five minutes to pot, finally, a single plant. When I turn out the soil in the autumn, the final potting compost falls away, as it contains few roots." Now, I myself have seen this condition of compost and plants. To spend nearly five minutes ramming soil down in a flower-pot is worse than time wasted. It defiles the object in view. Only moderately firm potting is needed; the Japanese varieties must not be potted quite as firmly as those of the improved section.

Position in Summer for the Plants.—Usually, when the final potting has been completed, the plants are placed in blocks close together for a time; but they must not be left so for any lengthened period. Put them 18 inches apart in rows running north and south, and allow a space of 4 feet or 5 feet between the rows. The pots may be placed on a bed of ashes, but they are best on tiles or boards. On the latter they do well lining garden paths, where it is convenient. Specimen plants should have a position by themselves. Two rows of wires, fixed to strong stakes, will be necessary for plants that grow 5 feet and more high, and one wire for plants under five feet. Always apply water through a rosed watering-can.

Persistent Bud Formation.—Some varieties give a lot of trouble and create much disappointment through persistently forming buds instead of growing on freely. A bud shows, it is pinched out, another young shoot appears and then it bears a bud, and so on until the summer is well advanced. The only thing to do is to remove these premature buds. I have tried topping the plants—that is, pinching off about two inches—but it was not a remedy; buds still formed. Sometimes a bud at the right date may appear and be "taken," and the resultant bloom is a passable one; but more frequently the bloom develops too late, owing to the late appearance of the bud that can, with confidence, be safely "taken."

Planting-Out for Lifting.—Where pots are scarce and many plants are required for the production of cut flowers, a number may be planted—say, in the kitchen garden or on a spare plot of

ground—with the object of lifting and placing them on Vine or Peach borders in the autumn.

A Simple Way of Planting-Out.—For many years I carried out the following plan. On a bed of ashes I placed the plants 2 feet apart in rows 4 feet asunder. Only a thin layer of soil was put under the plants, but the roots were well covered with good compost, and, as the season advanced, top-dressings were added. These plants, being close to a water supply, did remarkably well, and in the autumn were readily lifted by placing a strong garden fork under each, and conveyed to the border under glass, where they did not suffer any check. The plants so treated were dwarfer than others planted out, very bushy and thick flowered. Avon.

CULTURAL HINTS ON NEW AND RARE PLANTS.

(Continued from page 205.)

TREES AND SHRUBS.

Davidia involucrata is a large-growing tree from China, where it is reported to form a specimen as large as a Horse Chestnut. Although only introduced twelve or thirteen years ago, so amenable is it to cultivation that there are already numerous specimens 15 feet in height and over. Well-drained loamy soil suits it well, while it also thrives in soil of a peaty character. Cuttings of both young and fully-ripened shoots may be rooted.

Pyracantha angustifolia.—This may be recognised by some people under the name of *Cotoneaster angustifolia*, but the former is now considered the correct name. An evergreen shrub, it makes a worthy companion to the ordinary *Pyracantha*, and is a contrast by reason of its yellowish or golden berries. In the milder parts of the country it may be grown in loamy soil in an open border, but elsewhere it should be placed against a wall.

Styrax hemsleyana, a new species from Szechuan and Hupeh, is likely to form one of the most ornamental species of the genus, for it has whitish bark, bold foliage, and bears good-sized inflorescences of white flowers. Like other *Styraxes*, it may be planted in warm, well-drained, loamy soil containing a little peat.

HARDY PLANTS.

Primula bulleyana.—Among the moderns in the *Primula* world this is certainly one of the most beautiful and distinct, valuable alike for vigour, for amenability to cultivation in British gardens, and for newness of colour in its own family. The predominant colour is orange, but there are also tints of apricot, buff, and coral. The plant forms a good spreading rosette of leaves, from which the magnificent spikes of flowers, 2 feet to 2½ feet high, arise in June and July. A moisture-

loving species, nowhere happier than near abundant supplies of moisture in rich soils. Native of Western China, where at great elevation it is said to cover whole mountain meadows. Raise from seeds sown when fully matured.

Anemone scythnica.—This is one of the *A. Islanda* set, and one of the most charming plants of spring. Externally the sepals are coloured a deep purplish blue, the inner row of petals being white. In a group of it both colours are seen in the picture, the contrast of intense, almost gentian blue and pure white being particularly fine. Height 6 inches to 8 inches when established; habit tufted and highly ornamental. Loves

HUNNEMANNIA FUMARIFOLIA, A LITTLE-KNOWN PERENNIAL WITH
GRLEY FOLIAGE AND YELLOW FLOWERS.

deep, rich, light, sandy soils. Abhors clay. Raised to any extent almost from seeds, which, if sown soon after ripening, first flower at eighteen months old. Flowers March-April. A notable plant, good and cheap.

Campanula Profusion Varieties.—Most growers of choice Bellflowers have not yet realised that there are two distinct varieties of this plant, and both are good for their late flowering. One has self-coloured flowers of a good blue tone, the other sky blue, mauve-shaded flowers of exquisite delicacy and charm. For their late as well as abundant and profuse flowering they are recommended. Habit trailing. Spring cuttings, or division.

(To be continued.)

ROCK AND WATER GARDEN.

THE AMERICAN WOOD LILY.

(TRILLIUM GRANDIFLORUM.)

THIS year the American Wood Lily seems to have flowered with exceptional freedom in various gardens throughout the country. Not that it is in any way a difficult subject to manage, for it may be relied upon to flower more or less freely every year. Moreover, it is a most accommodating plant, for not only is it most at home in the partial shade of a woodland garden and in a cool, leafy soil, but it also flourishes as a semi-bog plant or in the drier position of a pocket in the rock garden. *T. grandiflorum* is one of those popular plants having the misfortune to bear a multiplicity of common names. Of the names given to this plant, that of the American Wood Lily appears to be the most appropriate, for it is a native of North America and belongs to the Natural Order Liliaceæ.

For naturalising in shady places it is well adapted, and when grown in the natural leafy soil of old woods it increases rapidly, while it does almost equally well on a deep and well-drained bed of peaty soil. Although there are a number of species, the subject of this note is unquestionably the most useful as a garden flower. The three-petalled flowers of *T. grandiflorum* are very chaste and snow white, fading to pale rose with age. The subject of our illustration on page 289 is that known as *T. grandiflorum roseum*. It is a suitable companion to the type, the flowers being of a rosy hue, deepening in colour after expanding.

A SHOWY MEXICAN POPPY.

(HUNNEMANNIA FUMARIFOLIA.)

This rather uncommon plant with bright yellow Poppy-like flowers might at first sight be mistaken for the better-known *Eschscholtzia californica*, to which it is closely allied. The subject of this note is the sole representative of the genus. It is a native of Mexico and takes its name after Hunnemann, a zealous botanist who died in 1837, while the specific name indicates that the plant is *Fumaria*-leaved. Coming from a much warmer clime than ours, it is not surprising that it should prove only half-hardy in this country. Seeds may, however, be sown in the open either in spring or autumn, and, providing protection from frost and wet is given in the winter, it will continue to grow for years, as it is of perennial duration. A turly rich soil suits it best, and it succeeds under much the same conditions as the lovely *Senecio pulchellum*. Not only is *Hunnemanna showy* when in flower, but it is also handsome in foliage, while for planting on the sunny side of the rock garden in a pocket sheltered from cold winds it is to be commended.

THE NYMPHÆAS OR HARDY WATER LILIES.

(Continued from page 207.)

Varieties.—Many lovers of the Water Lily have cultivated the older hybrids and found great satisfaction therein, as I know (almost too well) by the large amount of correspondence received at various times, yet they have not ventured to add to their collections some of the later hybrids, not by any means the newest and, consequently, the most rare, but those that are comparatively plentiful. Such, for instance, as the following, viz.: *Nymphaea Marliacea ignea*, a somewhat miniature growing hybrid and one well suited for fountains and shallow basins, with very brilliant flowers; *N. sanguinea* (*N. caroliniana*—*N. Laydekeri*, Marliac), another Lily for the fountain or basin, very free-flowering; *N. pygmaea Helvola* (*N. tetragona*—*N. mexicana*, Marliac, 1893), quite a gem, with pale yellow flowers, the smallest of all the hybrids and another good subject for shallow water; *N. odorata exquisita* (Marliac, 1898), a most lovely shade of rosy pink and of moderate growth; *N. caroliniana perfecta* and *N. caroliniana rosea*, two gems in their way; and *N. caroliniana nivea*, a pure white form, are all of Marliac's raising. The preceding are about the best that can be chosen for the purposes indicated. Others with more vigorous growth are: *N. Froebeli*, raised by the late M. Froebel of Zurich. This is not a hybrid, but the result of repeated selection from seedlings raised from *N. sphaerocarpa rosea*, and from first to last, when *N. Froebeli* resulted, a period of twenty years elapsed. *N. James Brydon*, an American-raised hybrid (*N. candida rubra*—*N. Laydekeri*, Dreer, 1902), a most profuse-flowering hybrid, and one of the most distinct, the colour being almost impossible to describe; a pinkish crimson may perhaps describe it. Its form, also, is globular, hence quite distinct, too, in this respect. *N. Marliacea chromatella foliis marmoratis* should be noted as a variegated form of this well-known hybrid.

A BEAUTIFUL GROUPING OF THE AMERICAN WOOD LILY IN THE ROCK GARDEN.

I have often been asked to name some of the best and most distinct of these hybrid Nymphæas. In my opinion the following constitute the best so far in cultivation: Whites—*N. gladstoneana*, *N. virginialis*, *N. Marliacea albida* and *N. caroliniana nivea*. Pale pinks—*N. Mrs. Richmond*, *N. formosa*, *N. Marliacea rosea* and *N. Colosseae*. Deeper pinks—*N. Masanello*, *N. suavissima*, *N. sumptuosa* and *N. Newton*. Yellows—*N. Marliacea chromatella* or *N. mooreana* (the last named of a deeper shade of yellow), *N. odorata sulphurea grandiflora* and *N. pygmaea Helvola*. Crimson and shades of crimson—*N. atropurpurea*, *N. Attraction*, *N. ellisiana*, *N. Escarbondole*, *N. Meteor*, *N. James Brydon*, *N. gloriosa*, *N. Froebeli*, *N. Marliacea flammea*, *N. sanguinea*, *N. William Falconer*, *N. Marliacea ignea*, *N. Robinsonii* and *N. Incida*. These comprise thirty of the very best, so far as I have taken note of them at various times.

Enemies.—Like all other plants that are cultivated in our gardens, the Water Lilies have some

enemies to contend with. The water mite (one that is, in a few waters, somewhat troublesome). The best remedy that I can advise for this is the use of finely-ground lime (not slaked lime, which is not quite so effective, I think). If very troublesome, then lower the water and destroy all that can be seen, and lime all the surface lightly before raising the water-level again. Too free a use of lime, be it noted, is prejudicial, in my opinion. Aphides will attack them at times. For this the remedy is spraying over the entire surface towards the evening, and with repeated doings if needful, selecting a dry, quiet time if possible. A mite or other small aquatic insect will eat away the leaves from the under side. For this the remedy is a well-proven insecticide at about double the usual strength of application. This should be forced under the foliage, so that it rises against the under surface of the leaves. Another and

large (or small, predominate) The mite or water rat is also an enemy to the crown, and this rodent will do a lot of harm possibly before he is detected.

Cultural Hints. In small basins and when fountains, too, are in play at times—anywhere, in fact, where the beneficial effects of the syringe can be utilised—it is well to syringe the plants overhead during hot weather and towards the close of the day. On our lake we cannot well do this, but I have raised a smile sometimes when I have said that our Water Lilies would be all the better for a good shower. If accessible and time can be given to it, it is a good plan to wade in and around the plants and remove any dead or decaying foliage, also where the leaf-growth is too thick. Old flowers can at the same time be removed. Occasionally I have noted that some leaves get scorched on very hot days. Remove these where it is possible to do so.

most determined enemy of the Water Lily, in my experience, has been the water-towl of divers kinds, from the black and white swans down to the moor-fowl. All grades have a liking either for the young bronzy leaves of many of the best hybrids or for the flowers themselves. The moor-towl will peck through the unopened buds of those of the highest colour; this is most provoking. Again, as I have alluded to, the same bird will appropriate the leaves of the individually small plants (these in most instances will be the choicer kinds), and this, too, is annoying, as if the leaves of the older varieties were not good enough for making their nests. Ducks will dive and peck out the hearts of small plants very persistently, while swans do a vast amount of injury in tearing off the leaves and swimming through the separate plants. Water Lilies, other than the common variety, cannot be grown as they should be where aquatic birds,

Congenial Positions.—Failure in many instances has undoubtedly arisen through planting Water Lilies in what may be termed running water. I have found out this to be the case by the numerous letters I have received upon the subject. I have in my travels taken note of where Water Lilies establish themselves in waters that are moving to some considerable extent. I watched for them all one day on journeying up the Rhine from Cologne to Mayence. At last I found a few in what we should term a back-water, where the movement of the water was not felt. In the same way and fashion I found them in the waters behind the city of Bergen in Norway, and also upon inland lakes, but always in such positions. Upon a sheet of water well above Coniston Lake—in a mountain tarn, in fact—I found them in rather deeper water, but where there was not much movement, all the same. When in Norway I looked in vain for

varieties with any tinge of colour in the flowers. Those with this characteristic, I am informed on good authority, exist in Sweden in considerable quantity. If it were possible, I should like to see these growing. I refer to such as *N. alba rosea* (syn. *N. sphærocarpa rosea*), which I never succeeded in growing satisfactorily at Gunnersbury. Water Lilies undoubtedly prefer quiet water, not so much so as to be termed stagnant, but where there is not a great variation. If I had, however, to deal with a sheet of water that was stagnant, and was thus a source of trouble and complaint, I would plant Water Lilies there. This would, I feel, obviate the difficulty by keeping the surface of the water quieter. Too great a depth of mud is not advisable, for this would encourage leaf-growth at the expense of flowers. I have known this to occur. The ideal position for Water Lilies is, in my opinion, an open, placid lake where the sun has full influence upon the plants and the water also. A considerable variation in depth is advisable. JAMES HUDSON, V.M.H.

Gunnersbury House, Acton, W.

FLOWER GARDEN.

SEASONABLE NOTES ON SWEET PEAS.

Disbudding.—Arising out of the decisions which have been reached by judges at great and small shows throughout the entire length of the country, it has come to be accepted that a spike of Sweet Peas for exhibition must be something approaching to 2 feet in length, and that it shall carry not fewer than four more or less floppy flowers set more or less gracefully on the stems. It is unfortunate that this should be so; but the fiat has gone forth, and no one is allowed to look at smaller, perfectly formed and arranged blooms on a shorter leg. To give the requisite length, severe disbudding of all lateral shoots must be one of the rules, and it will result in a plant that is grown purely for exhibition and not for the embellishment of the garden. The disbudding must be strictly followed up, or the desired end will not be achieved.

Watering.—No one doubts for an instant the imperative necessity of maintaining the soil about the roots of Sweet Peas pleasantly moist, but many people regard incessant watering with more than doubtful favour. And they are wise, for nothing so prejudices the progress of the plants or, in my opinion, more rapidly predisposes them to attacks of "streak" as constantly pouring cold, hard water from the man into the ground. Those who can avoid watering from start to finish save labour for one thing, and reduce the possibilities of failure to a minimum for another thing. It is, of course, difficult to reach so ideal a state, and often it is quite impossible to do so; but those who make it a rule to water only when it is necessary, and then to give enough to soak down

not less than 3 feet, should find their plants continue in health. At a modest computation one would regard three gallons to the square yard as the smallest quantity, and advise five gallons on light soil.

Mulching.—Herein lies the secret of avoiding the too frequent use of the water-pot. Cover the surface of the soil with some suitable material which will keep it cool and arrest evaporation, and on naturally holding soils it will rarely be found needful to give water. It is not always convenient to provide manure for this purpose, though the preference should always be given to it, because it provides a certain amount of readily

very dry, windy days. When arid conditions prevail, the plants lose a considerable amount of vital energy, and they are helped towards complete recovery by the treatment suggested. Not only this, but the syringing or hosing tends to increase the length of the stems.

Feeding.—When inexperienced growers see a plant in poor health or think that it is suffering from some dread disease, they promptly turn to the liquid manure tub in the confident expectation that applications of strong manure-water will restore it to health. Nothing could be further from the truth in respect of Sweet Peas or anything else. To derive benefit from special food a plant must be

in perfect condition, and, given this state, a Sweet Pea will not object to a varied and generous diet. The initial point will be to see that the ground is moist, and then to use the particular manure that is fancied. There is not so much in the kind as in the manner of giving it and the variety which can be imparted. A plant will always respond more readily to a fresh food than to one that has already been given twice or thrice, and this should guide the cultivator to the desirability of finding the change that is so beneficial.

DARWIN TULIP MASSENET.

The outstanding feature of this variety is that it is quite distinct in colour from any other. Not that it is brightly coloured; on the contrary, it is of a somewhat dull rose pink externally and flesh-tinted within. The shading of the flower is beautiful, and affords a pleasing contrast to the electric blue and green coloured base. The flowers, perfect in form, are borne on long, stout stems. When shown by Messrs. Bath, Wisbech, at a recent meeting of the Royal Horticultural Society, this variety gained what is this year a rare distinction for a Tulip, viz., the society's award of merit.

POTENTILLAS IN THE BORDER.

The value of the Potentilla in the border in summer is not now so much realised as in former years, although the wealth of variety offered is greater than ever before. To do them justice they should have a rich, well-maured soil, not too much subject to drought, and they ought always to be tied to stakes, unless they are planted on rockwork. The fine double hybrids are by far the best for border subjects, making large plants with crowds of their handsome, well-coloured double blooms. They are now too numerous to discuss under name, but a purchaser can hardly go wrong in selecting from a good hardy nursery catalogue. They may be had in almost every floral colour, from deepest brown, almost black, through reds, yellows and various shades, some being spotted and other almost marbled with various shades. S. A.

DARWIN TULIP MASSENET. A ROSE PINK VARIETY WITH AN ELECTRIC BLUE BASE.

available food and serves the primary intention of the mulch. Where it is not at command, turn to the mowings from the lawn, and spread them freely from within a few inches of the stems to 2 feet outwards from them. Failing grass cuttings, secure anything else about the place that will answer the purpose in view; and when nothing can be had, rely upon incessant hoeing to create a dusty condition on the top, as this will prove excellent, though not equal to manure or grass.

Syringing.—Although it is undesirable, except under compulsion, to give water at the roots, it is indisputably advantageous to hose or syringe the plants vigorously on the evenings of hot or

THE ROMNEYAS OR TREE POPPIES.*(See full page Supplement.)*

UNTIL about fifteen years ago only one species of the Californian Tree Poppy (*Romneya Coulteri*) was known to exist. Investigations made in 1898 by Miss A. Eastwood, Curator of the Herbarium of the Californian Academy, proved the existence of a second species, which she described under the name of *R. trichocalyx*. Both are natives of California. The exact date of the introduction of *R. trichocalyx* is not known, as it was in cultivation in this country as *R. Coulteri* previous to 1898. The first recorded flowering of the new species was in 1902, in the garden of Mr. H. C. Baker, Oakland, Almondsbury, Gloucestershire. Differences between this plant and the familiar vigorous growths of *R. Coulteri* were noticed, the late Mr. George Nicholson recognising the plant as Miss Eastwood's new species, *R. trichocalyx*, described four years previously. In the autumn of the same year (1902) this lady sent seeds to Kew, the plants raised flowering in about twenty months from sowing.

In habit *R. trichocalyx* is less vigorous than *R. Coulteri*, producing more growths, but the stems are thinner and more leafy. The buds of *R. trichocalyx* are round and hairy, those of *R. Coulteri* being more pointed and smooth. Though quite as good a garden plant as *R. Coulteri*, the subject of the illustration is readily distinguished when seen growing side by side with it, as it does not possess those thick, tall stems, upright habit and the substance of the less divided leaves of *R. Coulteri*. *R. Coulteri* was first introduced in 1875 by Messrs. E. G. Henderson and Son, and as the plants seldom mature good seeds in this country, most of the seed sold is obtained from California annually.

The Romneys are not of the plants we meet with thriving in every garden throughout the country. The experiences and successes under such widely different conditions of climate and soil are so confusing that one hesitates to recommend cultural details. Take, for example, the following letter published in *THE GARDEN* of August 12, 1905, from an Irish reader: "Sir,—I send you a photograph of my *Romneya Coulteri*, which has been a mass of blooms for the past three weeks. The plant is growing on a wall facing south-east, and has been in its present position for eight years since I planted it, a small plant, out of a 4-inch pot. It is now over twelve feet high, about five feet wide and blooms profusely every year. The soil of my garden is light, thin, poor and hungry, and the plant has never had any assistance in the way of manure of any sort since it was planted." The most unsatisfactory soil for Romneys is a wet, heavy clay. Those who have tried to grow the Californian Poppies in their garden and failed under ordinary conditions should try the following cultural recommendations: Choose a position at the base of a south or south-west wall, sheltered from the north and east. Take out a hole 2½ feet deep, put in the bottom a foot of brick rubble for drainage, over this place 18 inches of good sandy turfy loam,

a little leaf-mould, and point it with old mortar rubble or road grit to keep it open. This will ensure efficient drainage when the plants are at rest in winter, while ample supplies of water, including liquid manure, can be given the plants if the weather is dry in the summer. A mulching of leaf-mould or old decayed manure is also beneficial.

Romneys may perhaps be best described as sub-shrubby, for during a mild winter the stems and foliage survive. On the other hand, severe frosts kill the stems to the ground. Though flowers may be produced by the stems which survive, by far the best display is made by the vigorous young shoots which push up from the base and smother the old growths. The average height of these in the case of *R. Coulteri* is from 5 feet to 7 feet or 8 feet, occasionally more. *R. trichocalyx* grows about three feet to five feet high. Either of these

types otherwise sow as soon as they come to hand, even if it is November or December. Romney seeds are often very slow in germinating, and may not move for several months if they have been kept for some time. Cuttings made of the smaller ripened shoots in autumn which have not flowered will root under a bell-glass in light, sandy soil. They usually show little sign of movement till spring, when a few or most of the cuttings may start off. Success in propagation is also possible with pieces of the thick, fleshy roots in early spring. A plate, No. 495, of *R. Coulteri* was published in *THE GARDEN* for November 8, 1884.

A DAINY GREENHOUSE PRIMULA.*(PRIMULA MALACOIDES.)*

ALTHOUGH of comparatively recent introduction, this dainty Primula is already a favourite, and

PRIMULA MALACOIDES, A BEAUTIFUL GREENHOUSE PLANT THAT CAN BE EASILY RAISED FROM SEED.

plants, with six to twelve flowers open at one time, is a most beautiful and imposing sight. The flowers average 6 inches across, with shining white petals almost like slightly crumpled satin, with a large tuft of yellow stamens in the centre. The flowers are fragrant. The flowering season is from June to October. When once planted out in the border, Romneys should not be disturbed, for there are few plants which transplant so badly. Any interference with the fleshy roots is most detrimental to the plants, so that till large enough and the final position is decided upon, Romneys should be grown in pots. In most gardens it is as well to place a small mound of ashes round the plants in winter to throw off or absorb excessive moisture in winter.

The easiest and most satisfactory method of propagation is from seed. It fortunate enough to procure home-grown seeds, sow them as soon as

may be found in many gardens of this country. Moreover, it is being widely grown for market—a certain sign of popularity. The flowers are of a pretty pale mauve, produced tier upon tier in a light and graceful manner. Of free and easy growth, it is invaluable for cutting and for greenhouse decoration during the winter months. It is usually grown as a pot plant, but it is surprising to note how freely self-sown seedlings under a greenhouse staging will flower when allowed to. Seed may sown any time in the summer months, preferably in August. Sown in pans in a gentle heat, the seedlings should be potted off singly in 3-inch pots as soon as they can be handled. On no account should this Primula be coddled in a heated atmosphere. It is one of the most satisfactory of all flowers for the unheated greenhouse. There is a pure white variety now in commerce known as *P. malacoides alba*.

TREES AND SHRUBS.

LAURELS UNDER TREES.

AT one time the planting of common Laurels under tall forest trees to hide the soil where little else would grow, owing to the drip from the trees above and the absence of light below, was largely practised, and those who did so were well pleased with the result. Of late there has been a loud outcry about the wide use of common Laurel, and in a general way it has been vigorously condemned, too often, though, without the mention of a substitute. That is, in my opinion, a poor argument. Those who condemn a practice should suggest a remedy. Now, as to the value of the common Laurel under trees, when first planted, if properly tended, manured and annually pruned, a thick green screen is quickly obtained, and remains so for many years with close attention. There, however, comes a time when the plants become "leggy," showing the soil underneath, especially round the edge of the clump, and gradually becoming untidy. The remedy is to cut down the whole of the plants to within a foot or so of the soil, when new growth will push from the stems and become a thick mass of greenery again in a few years. While this is going on, how bare and untidy this part becomes! My plan is to take away all the Laurels, trench the soil as well as the roots of the trees above will admit, and add manure freely. Plant Irish Ivy quite thickly over the plot; this will in a short time make a dense green covering. The leaves from the trees above will annually enrich the soil, giving a filip to the growth of the Ivy. Here and there in the lightest places plant groups of Berberis Aquifolium, not less than 6 feet in diameter. In the still lighter places, plants of the common yellow Broom would succeed and certainly add variety. The growing of Ivy under the trees affords an opportunity to plant bulbs of the strong-growing kinds of Narcissus, like Emperor, Horsfieldi, Golden Spur and the old double Daffodil. I know they would not succeed so well as in the open, but a quantity of flowers would be obtained, all tending to give variety and brighten an otherwise dull part of the garden.

E. M.

A GOLDEN PÆONY.

(PÆONIA ARBORIA LA LORRAINE.)

VARIOUS references in praise of this beautiful Peony have appeared in our columns in the past year. It is a remarkable hybrid Tree Peony, raised by MM. V. Lemoine et Fils, Nancy. It is said to have originated from the crossing of P. Noutan with P. lutea. The bloom is globular in form, very full and double, and of a buff tone passing to golden yellow. When shown before the Royal Horticultural Society by Messrs. J. Piper and Sons, Bayswater, a few weeks ago it gained the

exceptional award of a first-class certificate, and was proclaimed one of the most striking novelties introduced to this country this season.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLE TABLES.

IN some gardens vegetables are thought more of than either fruit or flowers by the cultivator, and receive attention accordingly. The general rule is, however, that lovers of fruits and flowers also take a great delight in growing vegetables. To all those who are not well versed in their cultivation the following hints will be useful.

THE GOLDEN TREE PÆONY, PÆONIA ARBORIA LA LORRAINE, A NEW VARIETY WITH YELLOW FLOWERS.

New Zealand Spinach.—The Spinach crop is a very important one. In some light soils, however, cultivators often find it difficult to grow the ordinary round-seeded variety—the Summer Spinach—after the middle of June. The large, succulent leaves, so much coveted, cannot be obtained, as the plants will run to seed prematurely. There is no danger of this kind in the case of the New Zealand Spinach. A well-grown single plant will cover a space of 50 square feet in a very short time, and such a specimen will bear many pecks of fine fleshy leaves. In fairly light soils there is no difficulty in getting the young plants to make good growth at this season; but in heavy, clayey loam they are rather stubborn in this respect. However, the cultivator should not

hesitate to sow seeds now. The latter must be sown in drills about six feet apart, the drills being 4 feet asunder. Place a small quantity of lighter soil where the seeds are to be sown, and drop about half-a-dozen seeds, several inches apart, in it, lightly covering them, and, in the absence of rain, give water to hasten germination.

Beet in Heavy Soils.—Many cultivators make the mistake of sowing seeds of this vegetable too early. The resultant plants grow very slowly, of course, and then the roots are tough, lacking in juice and in colour when cooked. In warm soils seeds for the main crop may be sown late in April or early in May. Splendid roots will then result. In clayey soils the middle of May is soon enough to sow, but I should not hesitate to make a sowing about the middle to the end of June. In a clayey loam germination of seeds is then fairly rapid, and the roots, though small, are of very high quality, being well coloured, exceedingly tender and full of juice. If the weather and ground are both dry, pour plenty of water in the open drills; then sow the seeds and cover them with dry loam. This plan will induce quick germination.

Broad Beans.—Lovers of this vegetable—and they are legion—will not be averse to sowing seeds late in the season. Usually, one finds many rows of the plants growing apace in the spring. Some are spoiled through black aphides, and the pods of others are never gathered because there happens to be a glut. Too many seeds are sown at once, early in the year, and then, because there are Dwarf and Runner Beans and Peas in plenty, the Broad Bean is neglected. Now, a good variety of vegetables is always welcome, and in a dry season, when Peas often do badly, the Broad Bean will thrive and pod freely if grown on the north side of a wall or fence, and, moreover, in a clayey soil. Cultivators who have never tried this plan would be surprised at the satisfactory result. Seeds may be sown as late as the latter part of June and the early part of July. Early varieties must be grown. Two good ones are Beck's Green Gem and Harlington Windsor.

When five or six trusses of flowers have formed, pinch off the tops, and so induce quick podding.

The Silver-Skinned Onion.—Undoubtedly this is the best variety for pickling, but it is also a fine one for pulling in a young state for eating when in that condition. Many persons like young Onions at thinning-out-time, and the Silver-skinned variety may be so used, as well as for pickling purposes. Do not sow in rich soil. A good loam without manure will do. A very poor soil manured last spring or earlier in the winter will also answer the purpose. The bulbs will grow almost one on the top of another, so that the seeds may be sown fairly thickly, and, with the exception of drawing out for eating while young, thinning is not necessary.

G. G.

A New Californian Tree Poppy: *Romneya Trichocalyx*.

GARDENING FOR BEGINNERS.

THE STAKING OF SOME HERBACEOUS PLANTS.

THE staking of plants is an important operation in the successful management of a garden, be it small or large, under glass, or in the open ground. In either case the two chief points to bear in mind are the same, namely, appropriateness and neatness. Over-staking is as unsightly and as undesirable as the want of a stake is untidy and disastrous. At the same time, it should be borne in mind that no plant ought to be staked that will stand safely without so doing, for the two simple reasons that it would be waste of time and would produce a most unnatural result. Indeed, what may be called good staking often begets the latter state, but yet it must be done to save the lives of growths and flowers.

This brings me to where I want to say that some of our herbaceous subjects are suitable for a more artistic method of staking than that which is mostly in vogue. A glance at the illustration on this page will show what is meant. It is a bed of Delphiniums staked with branched, natural stakes as distinct from plain stakes, which are so commonly used; and I think few, if any, will doubt the more natural appearance of the plants as so supported when they have grown sufficiently to hide the stakes.

The latter may be put in position at one operation or two, as most convenient to the operator at the time the plants require them. For strong and tall-growing plants like Delphiniums the twice-staking practice is, I consider, the better. That is, put short, twiggy pieces of support around the rootstocks while they are short in growth; this will ensure a more compact habit, and the stakes will soon be lost to view in the upward growth of the plants. As these first stakes are outgrown, then the final ones are placed. For this purpose strong, bushy Pea-sticks trimmed into shape will do splendidly, or loppings from the thinning out of trees will answer, the kind used in the illustration happening to be winter prunings of an old Poplar tree. Whatever is used, it will be found wise not to have the stakes of a uniform height. Varying lengths of, say, 3 feet to 6 feet will be found to fit into each other better when being put in position, and these lengths will be the measure of assistance needed by average garden plants. Of course, sometimes a variety will throw up extra long spikes, or an extraordinary strong wind may prevail, in which cases resort can be made to an additional long cane or two—at any rate, that is how we meet such difficulties.

Although this form of bushy staking can be adopted for isolated plants, it is when seen in beds or large clumps of plants that it becomes most telling. The spikes stand up more free and graceful, because the general contour of the plants has been better preserved throughout their development than when bunched together with three or four stakes, and this after some of the growths have been allowed to fall about.

As mentioned above, there are other plants of the herbaceous border that can be so treated; in fact, will look much more effective if so done. Some of the more important are Pyrethrums, Papavers, Cantareas, Michaelmas Daisies (where grown in large clumps or beds), Paeonies, Eugeonias, Shirley Poppies and old plants of Carnations

These and any other seed-growers may with advantage to their general appearance be bush-staked, remembering, as with all staking, the work is easier if begun in the early stages of growth. These lines will probably appear too late for this year's practice on some of the subjects mentioned, but a note can be made of the method for another season by those with whom it finds favour.

C. TILNER.

The Garden, Kenilworth, Herts., N.

PARSLEY.

EXACTLY too many Parsley plants are grown in a given space, with the result that the leaves are not as fine as they ought to be. Neither are they as hardy. Small leaves and thin stems will not withstand moisture in the atmosphere nor frost

fully exposed to the scorching influence of the sun's rays. Plants of a permanent character, such as Azaleas and Deutzias, which are to be retained in their pots, require very careful treatment, and they will repay it. Plunge the plants almost to the rims of the pots in ashes, sand or ordinary soil, putting a tile under each pot to ensure drainage and prevent the ingress of earth-worms. Water need not be given so frequently, and the soil in each pot will be uniformly moist. If one side is fully exposed to the sun's rays, the soil on that side dries up quickly, and, in the case of peaty composts, it very often remains dry, notwithstanding frequent subsequent waterings. The result is that the roots perish, the plants lose leaves wholesale, and frequently they die. This is a good way to treat Roses, Camellias and similar plants in pots in the

A BED OF DELPHINIUMS WITH NATURAL SUPPORTS PLACED IN POSITION.

Strong ones will, and these are only obtained by sowing the seeds thinly early, thinning out, and the pinching out of the young point of the plant towards the end of August. The crop of Parsley for winter and spring use is a very important one, and to ensure its success, two sowings of seeds are advisable, one about the middle of June and the other the middle of July. The seeds must be sown in shallow drills on a border protected from the north and east winds, but open to the south and west. Only use old, rotted manure in the soil. Trench the latter 2 feet deep (as Parsley roots deeply) and, before sowing the seeds, tread down the soil firmly while it is comparatively dry, if of a light nature. Thin out the resultant seedlings quite early, and at the final thinning leave the plants 1 foot apart; then they will grow strongly.

PLUNGING POTS IN SUMMER TIME.

There are many plants in pots placed out of doors at this season of the year and allowed to remain

summer-time. It is important that the soil around the roots be kept in a regular state of moisture without much watering. B.

PLANTING DAHLIAS.

The first week in June is the accepted time for planting Dahlias in the open. This work, however, like most other gardening operations, is governed by circumstances, and it is never advisable to work entirely by rule of thumb. The ground in which Dahlias are to be planted should have been selected and thoroughly trenched in the winter, and again turned over and manured in March. It is most important that the plants should be well hardened off before planting out, and this is best achieved by plunging them in a cool frame. If unable to put newly-purchased plants in a frame, they may be planted out on arrival from the nursery. Under such circumstances it is advisable to cover the newly-planted dahlias at night with pots or boxes.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Summer Bedding.—It is now safe to put out all the more tender plants, including Begonias and Coleus, although it should be borne in mind that a little shelter for a few days after planting will assist the plants to become established.

Watering.—Even though the beds are moist at the time of planting, a few days' sun or drying wind causes a considerable strain on the plants, and a good watering or two may be necessary to keep them going till they root into the soil in the beds. When once they are well rooted, too free an application of water is apt to make such subjects as Geraniums very sappy, which is detrimental to their flowering freely.

Staking.—Tall-growing subjects, such as Fuchsias, Abutilons and Helianthus, should be securely staked at once, not leaving them till they have been injured by the wind, and the less obtrusively this can be done, the better it is for the appearance of the garden generally.

The Pleasure Grounds.

Bulbs.—By this date Crocuses will have commenced to dry down, and, for the sake of tidiness, patches where they are planted under trees should be mown over, using the scythe, following a few days later with the machine. Early-flowering Narcissus also will soon be turning yellow, and the same system of mowing may be adopted; but it is not wise to do this too early, or the bulbs will suffer.

Sowing Biennials.—Sweet Williams, Canterbury Bells, Anchusa and Delphiniums should now be sown, and where the ground is heavy it is wise to prepare a bed for them of old potting soil, or they may be sown in boxes, to be pricked out in beds as soon as the seedlings are large enough to handle.

Violas for making a spring show should now be sown, and where cuttings of named varieties do not come through the winter well, these seedlings are very useful, and make a really good show during April, May and June.

Rock and Water Garden.

Now that some of the early spring plants, such as Arabis, Aubrietia and Iberis, are going out of flower, it may be advisable to trim these back somewhat, so that they do not get out of proportion to the surrounding plants. Such subjects are often planted in greater quantities on now rockeries than it is desirable to have as a permanency, so they must be either cut back or pulled up to allow the proper development of the more choice and permanent occupants of the rock garden.

Aubrietias.—The choicer varieties may be propagated by taking off the soft-growing tips and pricking them out in boxes or pots in the cold frame, keeping the bright sun from them till they hold up their heads well, by which time they will probably be rooted. Two light varieties that please me much are Lavender and Bride-maid, the flowers in each instance being large and the habit of the plants good.

Plants Under Glass.

Humea elegans.—The inflorescences of this decorative plant will be greatly enriched in colour if the plants are stood out of doors in a semi-sheltered position; but care must be taken with the watering, as if once the plants are allowed to get very dry, the foliage will turn yellow. The seedling plants should now be ready for potting off, giving them the benefit of an intermediate temperature till they are established, when they may be removed to a cold frame for the summer months.

Capsicums or Peppers. These, if sown and potted off as advised in previous calendars, should now be ready for their training pots. For the smaller ornamental varieties 6-inch pots are quite large enough, but for the larger edible varieties 8½-inch pots are best. A good rich soil should be used, making it rather firm in the process of potting. A fairly warm temperature will suit them best for a time, using the syringe freely to keep down insect pests.

The Vegetable Garden.

Peas. About the date a good batch of late Peas should be sown, selecting the varieties that

do best in the particular locality in which one is situated. Gladstone and Autocrat are recognised as two standard varieties, and on heavy soil I have found the latter to do exceptionally well.

Early and Midseason Varieties that are podding should, in the event of dry weather, have a good soaking or two of manure-water, and on very light soils a mulching of short manure, well watered in, will greatly help them.

Fruits Under Glass.

Melons.—No time should be lost after the early batch of fruit is cleared in getting a second crop planted, giving the house a wash down and clearing out most of the old soil; this ensures a clean start, and certainly a greater chance of success, if fresh soil is given for each succeeding batch. When planting at this season, a little shading may be necessary for a few days; but it should not be left on longer than is necessary, as there is more difficulty in setting the fruit when the growth is unduly rapid and soft.

Hardy Fruits.

Strawberries. The early batches on warm borders are now showing colour, and protection should be given from the birds. Wherever possible, the nets should be raised high enough to walk under, and thus save a lot of trouble when gathering commences. Later batches in the open should have the trusses slightly raised from the ground by means of wires or strings running the length of the rows. This is especially desirable on two year and three year old plants, as the fruits and foliage being thicker, there is a greater tendency of the fruit rotting during a spell of bad weather.

Raspberries coming into bloom will be benefited by a good soaking or two of manure-water or a light mulching of manure, giving the ground a good hoeing first. Suckers taken off at this time and planted at once often make good canes by the autumn, though care should be taken when lifting to secure as much root with them as possible, and this method of making fresh plantations I consider preferable to planting matured canes during the autumn and winter.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Propagating Pinks.—This work may now be carried out, and is quite simple. Pull the young shoot backwards, thereby securing a heel, although this is not absolutely necessary; trim off the lower pair of leaves and make the cutting in the ordinary way. Insert in boxes of sandy soil which has been pressed firm, place in a close frame and shade from bright sunshine till rooted.

Border Carnations.—These should now be making vigorous growth, and will be benefited by a dressing of soot, after which run the hoe through the bed or border. Attend to tying, or if coil stakes are used, attend to framing.

Bearded Irises.—Here we have a border devoted to these attractive flowers, except that we have a few plants, such as Marguerites, Hyacinthus caudicatus and Chrysanthemums, dotted in among them. I think they look best in a mass thus. They will now be coming into bloom, and this is a good time to rename them, as in the case of misplaced labels or obliterated writing, identification is comparatively easy now.

The Rock Garden.

Planting Primulas.—There is now a great variety of Primulas available for the rock garden, and if watering is attended to there is no better time for planting new stock or moving that already in hand than just after the flowering period. *P. japonica*, *sikkimensis*, *rosea*, *Sieboldii* and a few others require moist conditions, and must be planted at the base, but those of the *nivalis* and *marginata* type prefer drier conditions. Good yellow loam will suit any of them.

Polygala Chamæbuxus.—Let me strongly recommend this beautiful little sub-shrub to those who do not possess it. Its fragrant Pea-like flowers of cream and purple borne in racemes last many weeks.

The Rose Garden.

Mildew.—The rosarian must ever be on the alert for this enemy. Sulphur is the enemy of all fungi, and this in particular. Spraying with liver of sulphur will prove effectual.

Watering.—Being deep rooters, Roses once established rarely require watering, except on very light soils. Spring-planted stock, however, require close attention, and should be well watered if drought sets in.

Plants Under Glass.

Seedling Begonias.—Seedling tuberous Begonias that have been pricked off into pans or boxes and seem to require potting up will do far better if planted out in a frame in rich, flaky soil. Here they will make rapid growth, and when they begin to show flower they can be potted up into 4-inch or 5-inch pots, in which they will make a good show in the front of the conservatory stages during the autumn.

Begonia semperflorens.—The popular winter-flowering Begonias have put some of the older species in the shade, but *semperflorens* and its varieties, such as *rosea multiflora* and *Frau Maria Brandt*, should not be overlooked. Spring-struck plants will now be ready for potting up into 5-inch pots. Loam, peat, leaf-mould and sand form a compost that suits them.

Hard-Wooded Plants.—Acacias, Cytisuses, Epacris, Deutzias and most hard-wooded plants should now be stood out of doors for the summer, and with the exception of Deutzias, which require all the sun they can get, they are better shaded from the midday sun. Any necessary pruning should now be attended to. Plants of *Azalea indica* should be left in a little heat till the flower-buds have been well formed.

Fruits Under Glass.

Pot Fruits.—These will now require close attention in the matter of watering, as trees often require to be watered twice a day in hot weather. Feeding should also be continued, seeing to it that the food contains a fair amount of potash and phosphates.

The Cape Gooseberry, or Physalis edulis. finds favour with some families. It is easily grown, succeeding well on the back wall of a vinery. It can either be raised by seeds or cuttings. It is a rapid grower.

The Hardy Fruit Garden.

Training Peaches.—Extra vigorous succession shoots should be nailed in, while those that are rather weakly may be allowed to grow at will for some time. By such means the balance of growth will be maintained.

Syringing.—Peach and Nectarine trees, and all trees on walls planted last autumn or spring, should be well syringed in the afternoon during hot weather. If green fly is present, put some XL All Liquid Insecticide into the water.

Watering.—Wall trees, especially those on south walls, must be watered at the root if the border becomes dry, and as the temperature of the soil will be pretty high, the water should be slightly warmed prior to its being applied.

The Vegetable Garden.

Early Cauliflowers.—These will be turning in for use in the course of a week or so, and if they turn in rather rapidly, they can be lifted and laid in behind a north wall, or cut and their bases stood in flat vessels containing a few inches of water, to be stood in a cool house or shed. If clubbing appears, water with a little nitrate of soda or with common saltpetre at the rate of 1oz. to a gallon of water.

Broccoli.—It will pay to lift the young seedlings from the seed lines and prick them out 3 inches apart in fine soil, leaving them there until it is time to plant them out in their permanent quarters.

Broad Beans.—Draw some earth up to the later sowings, and top early crops to facilitate the filling of the pods.

Jerusalem Artichokes.—If not already done, ease up the soil between the rows with the digging-fork, and earth up in the same way as Potatoes are earthed up.

Kidney Beans.—A late sowing should now be made, and it will be advisable to use an early variety, such as *Ne Plus Ultra*. Earth up the earliest sowing when 6 inches high.

CHARLES COMFORT.

Broomfield Gardens, Darvden's Mains, Midlothian.

NOTES ON TULIPS.

I FEAR I rather digressed last week in describing the striped (or broken) Tulips, for I did not confine myself altogether to those varieties which were actually in the Chelsea Show. I wish to remark that my selection as there given must not be taken as including all the very best. In passing on to the Darwin and Cottage varieties, I feel I must comment on a note that recently appeared in one of the gardening weeklies, in which the writer rather scoffed at this division, and said it was rather absurd, and that both ought to be simply called late flowerers. I frankly admit that there are a fair number of the Cottage which are very much on the borderland, and also that perhaps it is somewhat pedantic to refuse to call any bizarre (such as Jaune d'Enf and Clio) a Darwin. All the same, I hold that these designations do mark off distinct types, and that it is helpful and not harmful to retain them. Some spring I hope to see the Royal Horticultural Society holding a Tulip conference with the co-operation of some of the best Dutch authorities. The tangle of names is now very bad indeed, and I feel sure any attempt to unravel it would be greatly appreciated by amateurs and traders alike. But to get to the immediate purpose of these notes. I will commence with the Darwins. Among those not very much known I singled out the following: Louise de la Vallière, a lovely rosy pink, with a blue base—practically a self, large, well-shaped bloom, much more of a pink than the well-known Mr. Farncombe Sanders. Near to it, on Messrs. James Veitch's stand, was a smaller but quite as beautiful a flower, Pomona; it was still further removed from Mr. Farncombe Sanders in the rose pink direction. It looked as if it had had a thin wash of salmon colour all over it; it had a white base, edged blue, and on the three exterior petals there was a deeper flame of the same tone. The Bishop, a large flower of singular charm, attracted, so the attendant told me, much attention in Mr. C. Bourne's collection. I, personally, do not wonder at it, for it is one of my own special favourites among the purples, and is invariably singled out by visitors to my garden. The interior of the petals is a rich, glowing, true purple, while externally one gets the impression of the same colour seen through a thick grey veil. With age the purple develops and takes on a decided blue tone. The plant is tall, with a fine thick stem. Julie Vinot (syn. Princess Elizabeth) is a pretty shade of rose, which at the edges of the petals passes away to a blush. It has a clear white base, and is of the flat-sided shape that is seen in Orange King. It has the reputation of standing bad weather well. Moralis was in nice condition in Messrs. A. Dickson and Sons' gold medal group. It is a clean-cut flower of deep rich plum, with a decided "bloom" on the outside of the petals. It is a tall grower; one of the best of the very dark selfs. I was glad to renew my acquaintance with the pretty rosy scarlet Sweetheart. It is very nearly like Mr. Farncombe Sanders in shade, but not such a large flower. Its special charm and distinction consist in its beautiful pale blue base, which is quite away from almost every other variety. A flower which was new to me was Prima Donna. I always call this type in my own mind "edgers." Its three exterior petals have a broad flame of rich rose red, which is edged with warm flesh colour. In the early days of last century there was a certain class of Tulips called Baguets (see "The Florists' Directory," by James

Maddock, 1792), or drum-stick flowers. Prima Donna would have qualified for one of these, on account of its stem, which is exceedingly rigid. I spent a delightful hour or two on one of the mornings of the show in the company of Mr. P. R. Barr, going into the similarities and differences of some of the rather-alike varieties. We found out, what I had always suspected, that Massenet and The Dove were one and the same thing. We also took round some blooms of Pensée Amère and compared them with those of La Tristesse and Remembrance. While there is more red in the composition of the former, we found the latter very similar, only it had not such a clean look, owing to its dull, smoky base and the duller edging of the petals. These are three of the silvery purples, a fourth being Ronald Gunn, a truly magnificent example of the type. With the mention of Nauticus my Darwin list must end. Its first merit is that it is one of the less expensive kind; its second is its large size and pleasing shape; its third is its colour, which is rather a nice shade of rose. It attracted my attention when I was over in Holland this spring, and I was glad to see it staged at Chelsea. It should be more widely grown. It lasts well and is particularly bright when first open.

Among the Cottage section I would call special attention to Monument (syn. Panorama or Friday). It is a fine bold flower of a good shade of orange red, exceedingly effective when planted near a good yellow, such as Mrs. Moon or Parisian Yellow. A flower of much the same tone of red is Lucifer. Here, however, the three inner petals are far more orange than red. This, as it always does, gives it a lighter look *en masse*. Its yellow base also tends to the same end. Gondvink is the king of the yellow brown shades. Tall, of good proportion, free flowering, it commands instant attention, and few, if any, ever go round my garden without bestowing a word of praise upon it. It is the largest, tallest and most richly coloured of all the brown yellows. During the first day Messrs. Barr and Sons displayed their beautiful Cassandra. It is an exceedingly bright rose in colour, of medium size and height, and, as I know by experience, one of the most lasting of Tulips. It flowers on the early side. I also saw a vase of Albion (syn. Ada). It is a Tulip whose charms do not develop until it has come to a certain age. But from that time onwards it is a bloom of great refinement, pure white, with a halo of pale mauve round the interior of the base. In a room it must be placed below the level of the eye to see its full beauty. Last year, when I was honoured by a visit from the head of Messrs. Sutton and Sons' bulb department, that gentleman picked it out as one of the most pleasing in all my collection.

My final paragraph must be devoted to the recrudescence of the old florist breeder in Holland. All the large trade gardens there have a quarter where these are grown in collections. With some of these we are more or less familiar—Goliath (syn. Kingscourt and Cardinal Manning) is fairly well known, and appeared under one name or the other in several places. It is a curious blend of mauve and rose, which changes to an almost pure orange at the extreme edges of the petals. It is a tall grower and an attractive flower. A goodly proportion of those that are classed as Dutch (?) breeders are purples or deep mauves. Some, such as Bacchus, Mariana, Fabius and De Zwyger, are very fine indeed; but there—I am off the line again. They were not at Chelsea, and I must not describe them. JOSEPH JACOB.

ANSWERS
TO CORRESPONDENTS.

FLOWER GARDEN.

INJURY TO PHLOXES (*L. H.*).—The Phloxes are attacked by the stem weevil, *Tylenchus devastatrix*, and it is this which is causing the mischief to the plants. It would be well to remove and burn the affected shoots, and give the soil around a dressing of sulphate of potash. It is a difficult pest to eradicate when once it has gained a footing, and we fear spraying will do very little indeed in this direction.

LILY DISEASE (*A. W.*).—The Lilies are attacked by the Lily disease, for which no cure is known. The diseased shoots should be removed, for that will lessen the danger of the bulbs being attacked, and at the same time we would recommend you to remove the top layer of the soil to the depth of 3 inches or so, replacing with fresh soil in which some old mortar rubble has been mixed. The Lilies should be in a place sheltered from winds, and as free as possible from late frosts.

FRUIT GARDEN.

BLACK CURRANT AND GREEN FLY (*E. P.*).—The Black Currant is attacked by aphid or green fly. Spray with Quassia and soft soap as soon as you possibly can, and in the evening.

PEAR-LEAF BLISTER (*R. A.*).—The Pears are attacked by the Pear-leaf blister mite, but if they are all as bad as this we cannot recommend the cutting off of affected foliage, as we should do if the attack were a slight one. Spraying in winter with a lime sulphur salt wash is the best thing to do, and spraying now with a nicotine preparation may do some good.

PEACH-LEAF BLISTER (*S. G.*).—The Peach foliage is attacked by Peach blister. It is due, in the first place, to the presence of a fungus in the tissues. This fungus lives through the winter in the shoots which were attacked in the previous year, and it is therefore necessary to remove these as soon as the attack is seen to commence. At the same time the trees should be sprayed with ammoniacal copper carbonate. Cold winds and damp situations lay the plant open to attack more seriously than if the external conditions are satisfactory. Every care should be taken that the trees are protected as thoroughly as possible from exposure to these contributory causes.

KITCHEN GARDEN.

TOMATOES DISEASED (*Salopian*).—The Tomatoes are attacked by the fungus *Fusarium*. The spores of this fungus inhabit the soil, and to avoid its attacks the best method is to sterilise the soil by heat.

LETTUCE FOR EXAMINATION (*F. B.*).—The spots on the Lettuce leaves are not due to the attack of any insect or fungus, but to the accumulation of the reddish cell sap, which you will see is distributed all over the leaves in certain spots to a greater extent than usual. This is probably a result of these portions of the leaves being exposed to a lower temperature through winds catching them, or something of that kind, than were the other parts.

MISCELLANEOUS.

LARVÆ TO NAME (*K. M.*).—Several grubs had evidently been enclosed, but only one remained, with the broken parts of two others. The living one had killed and eaten the others. It was the larva of a ground beetle (*Carabids*), an extremely useful insect, as it devours others that are noxious to plants.

LARVÆ FOR IDENTIFICATION (*A. E.*).—We found only one of the grubs you mention and the mangled remains of two others. These were all the larvæ of carnivorous ground beetles, which devour many foes of garden plants, and are among the gardener's best friends. Nearly all carnivorous insects are active and have large jaws, while those that destroy garden plants are usually sluggish and have small jaws.

TO ERADICATE GARLIC (*S. R.*).—The only way to clear ground of Garlic is to keep the Garlic hoed up as often as it appears, never allowing the leaves or the flowers to appear. By repeated cutting down in this way the plants are gradually weakened and eventually killed. If, however, the leaves are allowed to develop, the bulbs are fed, and there is the greatest difficulty in stamping the weed out. It will probably take several years to clean the ground thoroughly.

NAMES OF PLANTS.—*Robin Hood*.—Small flowers of *Tulipa gesneriana spatulata*.—*A. B.*—1, *Cupressus pisifera squarrosa*; 2, *C. p. plumosa aurea*; 3, *C. lawsoniana*; 4, *C. lawsoniana* variety; 5, *C. l. erecta-viridis*; 6, *Lithospermum prostratum*.—*W. H. O.*—1, *Saxifraga cespitosa*; 2, *Silene pendula*; 3, *Sedum spurium*.—*E. L., Crouch End*.—1, *Pyrus torminalis* (Wild service); 2, *Sequoia gigantea*.—*L. E. W., Wells*.—1, *Saxifraga muscoides*; 2, *S. decipiens Rhei*; 3, *S. Geum*; 4, *S. umbrosa punctata*; 5, *S. Geum crenatum*; 6, *S. rotundifolia*; 7, *S. huddleyana*; 8, *S. Andrewsii*.—*G. G.*—1, *Saxifraga trifurcata*; 2, *S. sponhemica*; 3, *S. cordifolia*; 4, *Lithospermum prostratum*; 5, *Saxifraga rotundifolia*; 6, *Veronica Teucrium dubia*; 7 and 8, *Phlox subulata* variety.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THERE was a floral display of unusual brilliance at the fortnightly meeting of the above society, held at Vincent Square, Westminster, on Tuesday last. Hardy flowers, such as Irises, Pyrethrums, Peonies and Lupines, created a gorgeous display of colour, equalled only by the banks of Sweet Peas and Roses arranged on all sides. Greenhouse flowers were likewise well represented, Pelargoniums, Fuchsias, Schizanthuses and Orchids being among the most conspicuous.

ORCHID COMMITTEE.

Present: J. G. Fowler, Esq. (chairman), Sir Harry J. Veitch, Messrs. J. S. Moss, J. W. Potter, Gurney Wilson, F. A. Rolfe, E. Sander, S. H. Low, F. Meutoth Ogilvie, J. Charlesworth, J. Cypher, W. B. Batcher, G. Hunter, W. B. White, W. Bolton, R. B. White, de B. Crawshaw, S. W. Flory, A. Dye, J. E. Shill, T. Armstrong and C. H. Curtis.

Following so soon after the great Spring Show, one hardly expected to see such an extensive display of Orchids.

From Mr. H. S. Goodson, Furlawn, Putney, came a comprehensive collection of Cattleyas, Odontoglossums, Miltonias and others in season. Among the gems of the collection were *Odontoglossum anabile roseum*, *O. lambeolanum* and *Cattleya canhamiana*. A number of *Cymbidiums* and *Oncidiums* with long, arching sprays of blooms were shown in the background. It was a highly creditable group, admirably staged, and worthy of the society's gold medal which it received.

Messrs. Charlesworth and Co. showed a little group of choice orchids, including *Miltonia vexillaria*, *Empress Auguste Victoria*, of a deep rosy pink colour, *Silver Banksian* medal.

Messrs. J. Cypher and Sons, Cheltenham, showed the delicate *Oncidium pulchellum*, with *Dendrobium* and *Miltonia* in variety. *Silver Banksian* medal.

Messrs. Stuart Low and Co., Bush Hill Park, Middlesex, staged an admirable collection of Cattleya hybrids, also *Bulbophyllums*, *Dendrobiums* and *Odontiodas*. *Silver Banksian* medal.

A similar award was made to Mr. E. H. Davidson, Twyford, for *Odontoglossums* and *Cattleyas*. A grand plant of *Odontoglossum Aireworthii* orchid *Dece vari ty* was included, and gained an award of merit.

Messrs. Hassall and Co., Southgate, had a fine array of *Oncidium serratum*, together with such interesting species as *Odontoglossum Oro-Skammeri*, *Aerides crispiloba* and *Trichoplia bachhausiana*. *Silver Banksian* medal.

Messrs. William Bayler Hartland and Sons, Cork, sent a fine lot of *Odontoglossums* and *Cypripediums*, which looked none the worse for their journey across the Irish Channel.

A number of *Odontiodas*, including the beautiful *Yuzstekeke* and *roseiflenside*, were shown by Messrs. Armstrong and Brown, Tunbridge Wells. Two fine plants of the green-flowering *Coleogyne pandurata* and a number of *Brasso-Cattleyas* were also shown. *Silver Flora* medal.

Messrs. Sander and Sons, St. Albans, had a fine lot of *Miltonias*, of which *Empress Auguste Victoria*, with very large rose pink flowers, was conspicuous. The deep yellow of *Angiolia Clowesii* lent a pleasing tone of colour among a brilliant array of *Cattleyas* and *Masdevallias*. *Silver Flora* medal.

FRUIT AND VEGETABLE COMMITTEE.

Present: A. H. Pearson, Esq. (chairman), and Messrs. J. Cheal, E. Beckett, H. Hooper, P. W. Tuckett, W. Dymers, C. G. A. Nix, J. Davis, A. K. Allan and A. Bullock.

The only exhibit before this committee was that of a collection of Lettuce from Messrs. Carter and Co., Raynes Park, S.W. The Lettuce were all of the Cabbage variety, and arranged in beds just as they might be growing in frames or a border. The varieties shown were Holborn Standard, Continuity, Victoria, Harbinger, Brown Dutch, Marvel and Grand Admiral. *Silver Banksian* medal.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. C. T. Briney, J. Green, B. Crisp, T. Stevenson, C. Bick, W. A. Bilney, R. C. Notcutt, J. W. Moorman, R. W. Wallace, C. K. Fielder, J. W. Barr, E. A. Bowles, F. Pace-Roberts, J. Dickson, C. Dixon, J. Jennings, J. T. Bennett-Poe, Charles E. Shea, W. Cuthbertson, W. P. Thomson, E. H. Jenkins, W. J. James, E. Mawley, J. F. McLeod, G. Paul, A. W. Watkins, W. B. Cranfield and K. Hooper Pearson.

Messrs. Gunn and Sons, Olton, Warwick, displayed an admirable lot of herbaceous Phloxes in distinctive colour shades, showing these plants to perfection so far as this is possible in the forced plant. *Manve Queen*, *Flora* (white and pale mauve), *Fran Aufome*, *Rehner* (white), *Elizabeth Campbell* (salmony pink), *Le Mahdi* (violet), *Beauty of Arden* (dual pink), *G. Strolein* (fine scarlet) and *General Van Hentz* (also scarlet).

Messrs. W. and J. Brown, Peterborough, had a small group of *Gaillardias*, *Dianthus Napoleon III.*, *Heucheras* and a semi-double *Rose* of considerable promise.

Mr. C. W. Chandler, St. Mary Cray, Kent, set up a collection of Flag and other Irises, in which many good varieties were seen.

Messrs. Artindale, Shetfield, had a sumptuous group of Poppies, Pyrethrums, Erenmuri and Lupines, the first-named being particularly good and in variety.

Baker's, Wolverhampton, showed alpines on rockwork, *Dianthus Napoleon III.*, *D. salmona*, *Wahlenbergia vineiflora*, *Primula capitata* and choice Saxifrage and shrubs being noted.

Mr. Charles Bhek, Hayes, Kent, staged border Carnations in excellent form, handsome flowers in many colours, *Cecilia* (yellow, very fine), *Salome* (fancy heliotrope variety, perhaps the best of its class), *Skirmisher* (buff ground fancy), *Dora Bhek* (the finest buff self extant), Mrs. Warton (clear apricot self of distinct shade) and *Elizabeth Shiffner* (pale buff self) were among the best in a grand lot.

Messrs. Reamsbottom, King's County, Ireland, again exhibited their fine strain of St. Bridgid Anemones.

Mr. L. R. Russell, Richmond, had a small group of *Lyces*, *Acers*, *Olearias*, *Ceanothuses* and other plants. *Nertera depressa* was very charming.

Messrs. Barr and Sons, Covent Garden, had a group rich in Flag Irises, Lupines, single Peonies, Ranunculi, Spanish Irises and other showy plants of the moment. *Lilium colchicum* was very fine.

Messrs. Dobbie and Co., Edinburgh, displayed Sweet Peas and Antirrhinums, and for effect and garden display the latter undoubtedly took the lead. Naturally, the twin had been grown under glass, though the immediate result of this is to show what is possible with these easily-grown, easily-raised plants for the longest possible period. There is gracefulness and charm in these taller spires of the *Snapdragon* that endow them with great decorative value, and as the idea is unpatented, it may be copied by all. *White Queen*, *Yellow Queen*, *Defiance*, *White Beauty*, *Cottage Maid*, *Amber Queen* and *Moonlight* were among the best.

Messrs. R. H. Bath, Limited, Wisbeck, had a pretty display of Sweet Peas, together with a larger, showier group of late-flowering Tulips and Peonies.

Messrs. W. J. Godfrey and Sons, Exmouth, had a showy table of their art shades of Poppies in variety, also fancy and Regal Pelargoniums. The latter are not frequently shown, though they have an ornamental value of their own in the conservatory at this season.

Messrs. Kelway, Langport, arranged quite a feast of Pyrethrums, Peonies, Lupines and Larkspurs, the two former largely predominating. Of single Pyrethrums, *Rimdox* and *James Kelway* were good. Of doubles, *Aphrodite* is still without a peer among the whites, and *Lord Roselyne* (crimson) is the equal of any we have seen of this shade.

Messrs. Stuart Low and Co., Enfield, showed Malmaison and other Carnations in capital form, *Lady Coventry*, *Princess of Wales*, *Princess Juliana*, *Carola* and *Baroness de Brienen* being among the best.

Messrs. J. Cheal and Sons, Crawley, showed cut *Rhododendrons*, *Olearias* and other shrubs.

Messrs. G. Jackman and Sons, Woking, staged Irises, Lupines and other plants, their finest specimens being *Irish pallida*, *Princess Beatrice* and *I. p. Leonidas*, both noble varieties.

Messrs. G. and A. Clark, Limited, Dover, displayed some good groups of herbaceous things, nothing more stately or imposing perhaps than *Iris* *Reardiff*, which is of the pallid sort, *Thalicttrum Delavayi* was very charming, *Gemma*, Mr. J. Bradshaw and Mrs. Bradshaw being also well shown.

Messrs. G. Paul and Sons, Cheshunt, had an interesting gathering of single Roses, with such quaint things as *viridiflora* and others.

Mr. Amos Perry, Enfield, had an extensive exhibit of Irises and Poppies, together with *Thalicttrum aequilegifolium album*, which was very fine. Of the Poppies, which created quite a blaze of colour, *Orange Queen*, Mrs. Perry, *Perry's Unique* (intense scarlet with deeply-cut petals), *Melend* (deepest crimson) and *Crimped Beauty* were excellent. *Onosma echinoides* was also well displayed.

With arching Fuchsias overhead, and Irises, *Nemesis* and other flowers beneath, Messrs. James Veitch and Sons, Limited, Chelsea, formed a perfect avenue of flowers. The *Gloxinas* Veitch's *Giant Strain* were magnificent in white, violet, blue and reds of many shades, spotted varieties in abundance and others making a glorious display. The plants teemed with buds as well as with giant flowers. Irises, *Nemesis* in variety, the pretty white *Gilia dichotoma* and other plants in variety made a brilliant show.

Messrs. B. R. Cant and Sons, Colchester, had a fine group of Rambler Roses *Ilwatha*, *Dorothy Perkins*, *White Dorothy*, *American Pillar*, *Blush Rambler*, *Lady Godiva* (pink) and *Sweet Pea* (a single blush white variety not yet in commerce).

Messrs. Piper, Barnes, showed many well-flowered *Wistarias* in white and mauve, a few plants of *multijuga* being noted.

Aranaria excelsa *Silver Star* was well displayed in a ground group by Messrs. Roehford, Turnford Hall Nurseries, near Broxbourne. It is a prettily-marked variety with white tips.

Mr. James Box, Lindfield, Sussex, had a capital show of herbaceous plants, Poppies, Pyrethrums, double white *Rocket*, *Anemone sulphurea*, *Columbines*, and a glorious lot of *Peonia albiflora grandiflora* (a pure white, delightfully fragrant flowered plant enriched by a tuff of yellow anthers). It is a plant for everybody who gardens in the open air.

Messrs. William Fell and Son, Hitchin, had an arrangement of alpines on table rockwork, *Primula corburniana*, *Achillea argentea*, *Phlox pilosa*, *Primula sikkimensis* and *Onosma fatuica* being among the best. *Primula bulleyana* was also good.

The Messrs. Hopkins, Shepperton, showed many alpines and herbaceous plants on tableing, *Achillea Clavenna* and *Primula sikkimensis* being noted.

Messrs. Whitelegg and Page, Chislehurst, had good masses of *Heucheras*, *Gemm Mrs. Bradshaw*, *Wahlenbergia vineiflora*, together with plants of *Habrauthus pratense*. The *Heucheras* were very fine, one brilliant-flowered variety, *Scarlet Seedling*, calling for special remark.

Mr. Clarence Elliott, Stevenage, had one or two fine masses on his rockwork exhibit. The finest thing was a mantle of *Campanula Stevensii*, which must have contained many hundreds of flowers. *Myosotis rupeola* and *Arnica montana*, the latter not in very good form, were also noted.

Messrs. Peed, West Norwood, showed *Gloxinas* of a very good strain.

Carnations and *Gladioli* were well displayed by Mr. J. D. Webster, Chichester, who also had a very handsome vase of the yellow *Calla Pentlandii*.

Messrs. T. S. Ware, Limited, Feltham, displayed a group rich in Erenmuri, Peony, Iris, Lupine and other showy things, while such pretty free-growing alpines as *Linaria pallida*, *Stachys corsica*, *Asperula hirta*, *Sedum pilosum* and alpine *Phloxes* were employed with considerable freedom.

Baker's, Wolverhampton, had finely-flowered plants of *Primula Lissadell Hybrid*, *P. bulleyana* and *P. sikkimensis*.

Messrs. R. W. Wallace and Co., Colchester, had a table largely made up of Irises, of which *Caterina*, *Kashmir No. 1* and *pallida dalmatica* were three of the finest, *Erenmuri*, *Lilies*, *Pentstemon utahensis* (fine blue), *Calochort* and many other plants were shown.

Messrs. Bunyard, Maidstone, had a particularly showy exhibit of Peonies, Poppies, Pyrethrums, Lupines, Lilies, *Wahlenbergia vineiflora* and a fine grouping of Irises. A whole tableful of very showy plants.

Messrs. S. Bide and Sons, Farnham, had some three dozen vases of Sweet Peas in the leading sorts, such varieties as *Edrom Beauty*, *Walton P. Wright* (mauve) and *Melba* showing good culture.

Messrs. Cutbush and Sons, Highgate, showed a fine lot of Carnations and Rambler and other Roses, *Joan of Arc*, a new white *Polyantha*, being most charming. Lilies, *Watsonias* and hardy *Cypripediums* were also features of a good group, and were well grown.

Messrs. H. B. May and Sons, Edmonton, displayed a fine table of Ferns of a mixed character, *Peris*, *Adiantum*, *Davallia*, *Polypodium*, *Gymnogrammes* and the like.

Mr. Maurice Prichard, Christchurch, showed Peonies, Poppies, *Primula bulleyana*, *Wahlenbergia vineiflora*, and good masses of *Androsace lanuginosa* *Leichtlini* and *Incarvillea grandiflora*.

Messrs. James Veitch and Sons, Limited, Chelsea, displayed a magnificent lot of standard Fuchsias, admirably grown and flowered, above a groundwork of *Calcocaria Chibrant*. Pans of the choicer *Primulas*, *littoniana*, the new *Excelsior*, *bulleyana capitata*, Mrs. R. V. Berkeley and *sikkimensis* were all well shown.

Mr. A. G. Waley, Stone House, Reigate, Surrey (gardener, Mr. M. A. Dobson), displayed a pyramid of *Schizanthus* in great variety in admirably-grown plants. They were magnificently flowered throughout.

From Messrs. Sutton and Sons, Reading, came a superb collection of *Aquilegias* of the long-spurred strain. The colours included rich orange, pink and blue in a great range of colour tones, all of which come true from seed.

H. J. Tabbot, Esq., Little Gaddesden House, Berkhamsted, sent a group of *Stock Beauty* of Nice, a pink-flowered variety. The plants shown were about three feet in height and profusely flowered.

From Messrs. Carter Page and Co., London Wall, came *Violas*, *Pelargoniums* and *Dahlias* in great variety.

Messrs. G. and W. H. Burch, Peterborough, showed Roses in variety. Mrs. Foley Hobbs, a new sort, was shown in great form.

Mr. H. Burnett, Guernsey, was represented by a magnificent collection of up-to-date Carnations. The deep crimson *Carola* was much admired.

Tuberous Begonias, *Gloxinas* and *Aquilegias* were the features of a meritorious group staged by Mr. A. L. Gwillim, Sidecup, Kent.

A blaze of colour in Roses, Pelargoniums, *Calcocarias* and *Cannas* was created by the display from Messrs. Cannell, Swanley, Kent.

Messrs. Thompson and Charman, 11, Adam Street, Adelphi, W.C., showed Lupines, *Achillea rupestris*, *Campanula punctata*, and *Viola gracilis* above a host of hardy flowers.

The greenhouse annual *Statice Suworowi* and variety alba, together with new *Azaleas*, were shown by Messrs. R. C. Notcutt of Woodbridge.

Mr. G. Renthe, Keston, showed a collection of interesting hardy plants, among which we observed Irises in variety and *Primula sikkimensis* in quantity.

FLORAL COMMITTEE'S AWARDS.

Silver-gilt Flora Medal.—To Messrs. Dobbie for Sweet Peas and Antirrhinums; and Messrs. Veitch for Fuchsias, *Gloxinas*, &c.

Silver-gilt Banksian Medal.—To Messrs. Cannell, Swanley, for *Cannas* and Pelargoniums.

Silver Flora Medal.—To Messrs. Bunyard for herbaceous plants; Mr. Burnett for Carnations; Messrs. B. R. Cant for pot Roses; Messrs. Kelway for hardy plants; A. G. Waley, Esq., Reigate, for *Schizanthus*; and Mr. Webster Chichester, for Carnations.

Silver Banksian Medal.—To Messrs. Bath for Tulips and Sweet Peas; Mr. Box for herbaceous plants; Messrs. Burch, Peterborough, for Roses; Messrs. Clark, Dover, for herbaceous plants; Messrs. Cutbush for Roses; Messrs. Gunn for Phloxes; Messrs. Jackman for herbaceous plants; Messrs. Low for Carnations; Messrs. May for choice Ferns; Mr. Perry for Poppies and Irises; Mr. Renthe for hardy plants; Mr. Russell for shrubs; Messrs. Wallace for hardy plants; and Mr. Bick for Carnations.

Bronze Flora Medal.—To Messrs. Cutbush for Carnations; Messrs. Godfrey for Poppies, &c.; Mr. Gwillim for *Gloxinas*; Messrs. Piper for *Wistarias*, &c.; Mr. M. Prichard for hardy plants; Messrs. Ware for alpines; and M. Drummond, Esq., Southampton, for *Aquilegias*.

EDITORIAL NOTICES.

Every description of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

The Long-Spurred Columbinæ.—Few hardy flowers are capable of affording so much pleasure as a well-grown colony of these beautiful plants. Their long spurs, graceful pose and exquisite art colour shades appeal to all, and if cut in a young state they will last several days in water. Although it is generally assumed that these hybrid Columbinæ are short-lived, this is not always so. When visiting Messrs. Dobbie's trial grounds at Mark's Tey in Essex last week, we were interested to see a large bed of plants that had been undisturbed for at least ten years.

Berberis stenophylla as a Hedge Plant.—This is one of the most ornamental of our hardy flowering shrubs, and as it is evergreen it is a valuable plant, even when it is not in bloom. It is of garden origin, the parents being *Berberis empetrifolia* × *B. Darwinii*, both of which are natives of Chili. Apart from its value as a shrub, it is an excellent subject for forming a hedge, either as a boundary or as a screen. It should be cut back to its shape as soon as the flowers are over, and it will then send out good, strong growths, which will give a wealth of blossom the following spring.

A New Pedicularis.—The marsh-loving Lousewort (*Pedicularis palustris*), which is now flowering profusely in many damp places of this country, may find a rival in the new species, *P. siphonantha*. This species has been collected by Mr. F. Kingdon Ward in South-Eastern Thibet, where it grows in damp, grassy meadows at an elevation of 11,000 feet. It has curiously-shaped flowers, red in colour and borne close to the ground. It was one of the new alpinæ shown in the Farrer Cup collection by Messrs. Bees, Limited, at the Chelsea Show.

A Golden-leaved Oak.—In *Quercus rubra aurea*, the North American Golden Oak, we possess a valuable tree for effective planting in the pleasure grounds and park. Some of the so-called yellow-leaved shrubs are little better than an unhealthy-looking green-leaved tree, but this cannot be said of the subject of this note. It is a rich golden yellow in spring, the colour being most effective with a background of evergreens. By the side of the Broad Walk at Kew a tree, about twenty feet high, is most effectively placed with a background of Corsican Pines (*Pinus Laricio*), and in the foreground a large bed of *Rhododendron* Lord Palmerston, or, as it is sometimes named, *Cynthia*, with rosy crimson flowers.

Roses and Green Fly.—We do not remember seeing Roses so badly infested with green fly or aphid as they are this year, and judging by reports received, the trouble is very widespread. Undoubtedly the best method of combating this pest before the flowers are actually open is to spray with any of the insecticides advertised in our pages. When the blooms are open, however, they are apt to become soiled by such treatment, though even

then it is better to sacrifice a few than to let the pest get the upper hand. Where a good force of water is available, a severe hosing will dislodge large numbers of insects, and if repeated two or three evenings in succession, will do much towards cleansing the plants and cause no injury to the open flowers.

When to Sow Wallflowers.—Although there is considerable difference of opinion as to the best time to sow Wallflowers, we think that for Southern Counties there is no better period than early June. Earlier-sown plants get too large, while those raised much later do not have time to make specimens sufficiently sturdy to withstand the fogs and frosts of winter.

Cutting Back Aubrietias.—Now that the flowers of these plants are going over, it will be found advisable to cut off all the old flowering shoots, as it gives the plant a more compact habit and also encourages a quantity of new growths, which, when large enough, make excellent cuttings for propagating. They should be placed in sandy soil under a hand-light, and in this way a good stock can be obtained, which will be found of great value next spring, either for massing in the rockery or as a carpet for bulbs in the flower garden. Another good method is to work some fine soil among the old plants; this will encourage new roots, and the plants can be taken up in the autumn and divided into good, well-rooted pieces.

Gloxinias for a Cool Greenhouse.—There is a tendency on the part of many to regard *Gloxinias* as stove plants, the result being that they are grown much too warmly, and have, consequently, a weak and drawn appearance. Added to this, they are under such conditions more liable to be attacked by insect pests than when they are grown cooler and in a more robust fashion. However fine the flowers may be, they lose a good deal of their beauty when they are associated with loosely-disposed, thinly-textured leaves. So carefully is seed saved nowadays that it is quite the exception to increase *Gloxinias* in any other way, though not so very many years ago they were largely propagated by means of leaf-cuttings.

The Yunnan Rhododendron.—The wealth of *Rhododendrons* in the flora of China is yearly being brought more prominently before us as the plants raised from seeds collected by Mr. E. H. Wilson reach the flowering stage. *R. yunnanense* was first introduced to this country in 1894. This was prior to Mr. Wilson's first journey, though seeds of this species and the allied *R. ambiguum*, *R. harrovianum*, *R. benthamianum*, *R. concinnum* and *R. siderophyllum* were sent home by him from China. The Yunnan *Rhododendron* is one of the small-leaved evergreen section, freely branched, and covered at the latter half of May with Azalea-like blossoms. These are white, with just a tinge of mauve and the usual spotting. The bushy plants grow to 3 feet or more in height, forming useful subjects for beds or groups in a shrubbery border.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

How to Grow *Ourisia coccinea*.—In reference to the note by Mr. Arnott on page 275 of May 31 issue, I have some two year old plants which have thriven and spread, and have given a great number of blooms this year. They are planted immediately over the ledge of what forms one of the cemented divisions of my bog garden, over which the water flows from the upper to the lower part. The soil consists of peat, loam and leaf-mould, and is, of course, continuously moist.—FRANK R. ELGOOD, *Northwood, Middlesex.*

Grouping for Colour.—However carefully we may intend to make our garden colour-pictures, sometimes the plants stray away and do it still better by themselves. Such an example has just occurred in the case of a piece of dry walling

room, for instance, sweet-scented flowers cannot be endured, although the lovely colours and forms can. I myself speak from a four months' experience of deliciously-scented flowers in my own room. They had to be taken out from time to time. I do agree with "Anne Amateur," however, that those kinds of flowers, naturally sweet-scented, ought always to retain that characteristic. Fancy *Mignonette* without any perfume!—B.

***Saxifraga longifolia magnifica*.**—Under this name Mr. J. Grandfield, gardener to Sir Everard Hambro, K.C.V.O., Hayes Place, Hayes, Kent, exhibited on June 3 one of the noblest examples of the Pyrenean Rocktoil seen in cultivation. The specimen had been pot-grown, and not in the whole of my experience have I seen anything so handsome or so good. The great pyramidal inflorescence was shapely and well framed, and, I was pleased to note, had been permitted its natural bent. The flowers, too, were almost twice the size of those usually seen, pure and shapely

due to pruning. It is a Rose which should be cut back very hard; it then makes strong, sturdy wood. My plants were seen by hundreds of people last year, and they all agreed that it was one of the best Roses in the garden. The first season we had them in the open in the nursery, I told Mr. Mount, who distributed it, it was no use; but I had to alter my opinion and tell him last autumn that I consider it far and away the best yellow Rose.—WILLIAM H. CUTBUSH, *Highgate.*

— In your issue of June 7, page 287, you say: "The drooping habit of this Rose is undoubtedly a great drawback, but this could be tolerated if the colour were good. We have never seen blooms of really good colour from outdoor bushes in a fully-exposed situation." Had you been in Duns last autumn and seen the Rose referred to blooming in the open and in a fully-exposed position, you could never have truthfully penned the above, as Lady Hillingdon could have been seen here with blooms of exquisite colour.—JAMES D. LAWRIE, *Duns.*

Roses with Beautiful Stems and Foliage.—I fully agree with the editorial note on this subject on page 273 of May 31 issue. There are many varieties of Roses which possess very beautiful leaves and stems. I would add at least one variety to the short list named, and that is *Mme. Berard*. When well established in a suitable position, this Rose flowers freely, and the buds and full-grown blooms are very lovely. With me, however, the plants never did flower well, but there was some compensation—the leaves, especially the young ones, were very rich, rivalling the autumn tints of foliage of various kinds. For table decoration the young tips of the shoots may be used to great advantage. When so employed, the young shoots must be cut off about twelve hours previously and wholly immersed in water in a very cool room; also wrap them in damp paper while taking them to the show. They will remain fresh for six hours.—SHAMROCK.

Aubrietias: What is a Novelty?—Among the novelties we are to expect next year, I note a new *Aubrietia*, but I cannot think the description of its colour is a recommendation. I have long maintained that the dirty colours of many of these most valuable rock plants render it almost necessary to have a separate rock garden for each variety, and the announcement that the new-comer is described as a "curious smoky purple" is most discouraging. Why not try the effect of a weak solution of weed-killer? Sometimes Nature allows man great liberties with her colour-box, but he has abused the privilege in the *Aubrietias* and in some other flowers. I look in vain for good clear colours or really pleasing shades. Lavender is a beauty; the trio, too much alike, Mrs. Lloyd Edwards, Dr. Mules and Prichard's *AI* are lovely—but one has to be careful in placing these uncertain colours; while *Fire King*, *Leichtlinii* and a number of similar shades are impossible neighbours to almost anything. I also have some seedlings of a "smoky purple," but to my mind they are "rogues." Of course, tastes differ, but there seems to be an idea that any colour variety is necessarily a "novelty," whereas a novelty should be an advance in most, if not all, ways. It has no claim simply because it is a new shade, and a dingy shade too. Should such very doubtful "novelties" be encouraged, and should they receive awards from those in a position to grant them?—ERNEST BALLARD, *Colwall.*

A SUPERB PLANT OF *SAXIFRAGA LONGIFOLIA MAGNIFICA* THAT WAS EXHIBITED AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW LAST WEEK.

laing nearly north. For a yard or two the spaces are nearly filled with *Saxifraga cymbalaria*. In some of the lower joints *Corydalis ochroleuca* has established itself, and *Meconopsis cambrica* is in the lower joints and at the foot. It is true that all these plants are in the same garden region, but nowhere are they so well arranged or so prettily brought together as in this particular place, where they have come of their own will. As a harmony of full and tender yellow with fresh green foliage it could hardly be better.—G. JEKYLL.

A Plea for Perfume.—On page 275, issue May 31, "Anne Amateur" has a very interesting note on perfume in flowers. I once expressed my regret that a certain flower lacked perfume. "It is sweet-scented," I said, "it would be perfect"; this to a brother-gardener. I was much astonished to find that he did not agree with me. He said, "If all flowers were sweet-scented, many persons would have to discard numbers of them, because everyone cannot endure the sweet scent—often very sickly—of the blossoms." In a sick

withal. Obviously the plant was a veteran, as witness its giant rosette of leaves; and though a few weeks hence the Hayes collection will know it no more, seeds will be presently forthcoming, from which useful stock can be raised. The measurements of this fine plant, for which a cultural commendation was given, were as follows: Length of inflorescence from the top of the rosette, 2 feet, its basal diameter being 16 inches at the same point. The rosette of leaves had a diameter of 14 inches, the plant being grown in an 8-inch pan. It is believed to be about fifteen years old.—E. H. JENKINS.

Rose Lady Hillingdon.—May I disagree with your footnote on page 287, issue June 7? When this Rose was first distributed I was of your opinion, but I now think it is the best yellow Rose we have. I have a bed of it in my own garden, which is rank clay (my garden was a pottery two years ago), and the blooms last season were a most perfect colour, many of them being practically upright. My opinion is that failures are largely

How to Grow Viola pedata. In reading Mr. Arnott's little article on *Viola pedata* in a recent issue of THE GARDEN, I was particularly interested regarding the accepted opinion that its successful culture is exceptionally rare. I think it might perhaps interest you to know we have *Viola pedata* growing here in a perfectly healthy and vigorous condition, and is at present showing bloom. Its position is facing north, between two buildings, being a sort of passage where nothing in the way of shrubs would thrive. It occurred to us to turn the place into a rockery—which we did—planting, among other things, roots of this charming *Viola*. I simply put them in a bed of leaf-soil, loam and sand, and they have been, and still are, a splendid success, not having lost one plant. It seems rather extraordinary to find them growing so freely and easily, for, as Mr. Arnott says, it is "a notoriously difficult alpine to cultivate."—J. SIMPSON, *Sutton Hall, Chesterfield*.

Does It Pay to Spray Potatoes?—In reference to the note on page 225, issue May 10, I unhesitatingly say, "Yes, it does, and the man who does not spray is a loser in crop, soundness of tuber and quality." In this neighbourhood Potatoes are largely grown, and those who spray twice and sometimes thrice gain as much as five tons per acre over those who do not spray at all. Apart from preserving the tubers in a sound condition, the haulm is kept in a growing state so much longer; hence the increase in crop. So few persons who do not spray seem to grasp the advantage of keeping the haulm growing for two months longer than otherwise would be the case when disease seizes it. Last year I started on one side of my six-acre plot, doing one-third of it. For some reason the remainder was done at intervals. The difference in the sprayed and the unsprayed portions was striking, especially from stage to stage in the growth of the haulm. Spraying should commence when the haulm is 6 inches high; in fact, directly earthing-up is complete, and should be repeated once in the case of early and mid-season sorts. In the case of late varieties, three sprayings should be done. It is not the curing of the disease that is attempted; it is the prevention that is the all-important point to study. When liquid spraying is done, plots of one or two acres can easily be done with a knapsack sprayer—Hartjen's "Holder" Pneumatic, for example—as with the ordinary lances and nozzles attached to this sprayer the work can be effectively done. The under surface of the leaves and stems especially are the all-important parts to thoroughly wet with Strawsonite. Dry spraying is likely to become more popular than liquid spraying where large areas have to be done, as the saving in labour—water-cart and mixing—is considerable. There is one drawback, though, in this. Dry spraying can only be done during a limited period, when the haulm is damp from dew or light rain. In the case of the former, very early attention is necessary, a start having to be made as early as 3 a.m.—E. M., *Hants*.

FORTHCOMING EVENTS.

June 17.—Royal Horticultural Society's Meeting and Gladiolus Show. Lecture at 3 p.m. by Professor G. Henslow on "The Evolution of Plants and the Directivity of Life as Shown by Vegetative Structures." Oxfordshire Royal Horticultural Society's Show.

June 18.—Yorkshire Gala (three days). Royal Jersey Horticultural Show (two days).

RESULT OF OUR ROCK GARDEN COMPETITION.

No fewer than seventy sets of photographs of rock gardens were sent in for this competition, and, after careful consideration, the judges have awarded the first prize of five guineas, or a silver cup of that value, to:

Mr. W. A. Cook,
The Gardens, Leonardslee,
Horsham, Sussex.

Second prize of two guineas, or books of that value, to:

Mr. T. Matthews,
Brockhurst Gardens,
East Grinstead, Sussex

Third prize of one guinea to:

Mr. A. Weiss,
Drynham, Outlands Chase,
Weybridge.

The rock gardens of Mrs. Green, The Curragh, County Kildare, Ireland; Mr. W. E. Hawkins, Longfords House Gardens, Minchinhampton, Gloucestershire; and Mrs. H. Scott, Cadeby, Market Bosworth, are highly commended.

The photographs of the winning gardens, together with descriptions of the same, will appear as early as can be arranged. A number of the rock gardens depicted in the photographs sent in showed serious faults. In many instances they were arranged in close proximity to the dwelling-house, while in others dense trees were overhanging. In a few, rustic pergolas had been introduced, and in one, at least, weeping standard Brooms were planted. All these features should be avoided where possible. The placing of the rock, however, seems to be the greatest stumbling-block, many of the examples being unnatural and quite unsuitable for plant-life. We hope in the autumn to publish a series of articles on rock garden construction, with diagrams showing how the rock should be placed. Owing to a clerical error, we regret that many of the non-successful photographs were returned without the intended letter of thanks, and we therefore take this opportunity of thanking all those who entered the competition.

THE ROSE GARDEN.

PLANTING OUT ROSES UNDER GLASS.

EACH year the demand for early Roses increases, as evidenced by the huge structures that are erected by some of our leading commercial florists. Now, it is good for the grower that this is so, and doubtless he supplies thousands of people with blooms who have not the convenience whereby they could grow their own. But yet there are numbers of establishments in the country where it would be possible to devote a house or houses to the culture of indoor Roses; and this article is penned just as a reminder to some readers that now is a good time to make a start. First of all, place your order for young pot-grown plants growing in 5-inch pots. These should be of the current year's grafting, usually worked in January.

Preparing the Borders.—The next step would be to prepare the borders inside. A nice light span-roofed house running north to south would be best, and should be well equipped with ventilating

gear on both the east and west sides of the roof. Side ventilation will also be advisable. I would prefer a house having a movable roof, or, better still, one of the movable structures. Of course, this cannot be arranged under such short notice, but it might be possible for another year. Good Rose soil is essential; that is, a nice strong loam, with plenty of good, well-rotted farmyard manure worked into the subsoil. Let the soil be trenched at least two feet deep, and some basic slag placed in the lower spit at the rate of 6oz. to the square yard.

Distance Apart to Plant.—Having prepared the borders, about a fortnight should be given them to settle down, and then the plants which have arrived in the meantime may be set out 3 feet apart each way. This seems a lot of space for a small plant to occupy, but in a year or so it will be none too much. I have seen plants of *Niphetos*, *Bridesmaid* and similar varieties of about ten years old that have been 5 feet high and 3 feet to 4 feet through.

It does not matter if the house is a lofty one, as many growers prefer that there should be plenty of air. Cultural details, such as well spraying in the mornings and afternoons of fine days, together with careful root watering, must be given attention, and a look-out kept for aphid and mildew. *Auto Shreds* are one of the easiest exterminators of green fly, and there are plenty of remedies for mildew.

Training the Plants.—Some of the plants may need tying out to sticks, for it is important that each leaf obtains all the sunlight it can get. By the autumn the growth made will be amazing! In the early stages of growth—indeed, until autumn—the buds should be pinched off. If the soil is lightly covered with some old hot-bed manure, this will prevent too rapid evaporation; consequently, less water will be needed at the roots, but, before applying it, it will be well just to lightly loosen the surface. Free ventilation may be given on the top ventilators, but keep the sides closed. A moist, humid atmosphere is best for quick growth. Some good varieties to begin with are *Sunburst*, *Mrs. George Sawyer*, *Richmond*, *Lady Hillingdon*, *Liberty*, *Mme. Abel Chatenay*, *Souvenir de Gustave Prati*, *Molly Sharman Crawford*, *Mrs. Aaron Ward*, *Lady Pirrie*, *Rose Queen* and *My Maryland*. In order to grow the long-stemmed, big-flowered sorts, such as *Frau Karl Druschki*, *Mrs. John Laing*, *Ulrich Brunner*, *Captain Hayward* and *Caroline Testout*, I would suggest a separate structure, and in their case it would be best to put in open-ground plants in the autumn and build a structure over them after they have been established a year.

A BEAUTIFUL NEW ROSE.

ONE of the most charming novelties from Newtownards is *Carrie*. I do not know any Rose that has pleased me more, and to attempt a description of its lovely tints is all that I can do. There are present orange carmine, bluish buff, creamy fawn and coppery salmon, all colours that attract the eye; but when the coppery salmon hue prevails, as it frequently does, it is most delightful. The form of bud is nearly as long as that of *Mrs. Alfred Tate*; it is altogether a fuller Rose than this, and will make a most charming coat-flower. The growth is vigorous, erect and branching, and the flowers are produced in great profusion. I congratulate Messrs. Alex. Dickson and Sons upon raising this really delightful Rose, and predict a great future for it. DANECROFT.

TREES AND SHRUBS.

SOME GOOD WOODLAND EFFECTS.

MANY very beautiful and pleasing effects are possible in the woodland, wild garden and pleasure grounds with annuals and biennials. In such places we must, first and foremost, try to copy or imitate Nature as far as possible by sowing or planting in a natural manner. Formal planting will set up a jarring note instead of appealing to the taste of those who love the artistic and natural.

While seeds of Forget-me-nots, Foxgloves, Honesty and the Giant Balsam (*Impatiens Roylei*) may be scattered freely in any bare place where the plants are likely to thrive, the positions for the boldest groups should be chosen with care. Suitable

suburban garden where other plants which require good cultivation will not thrive satisfactorily. Tufts of Forget-me-not or Honesty may be grown in bare places between shrubs, or associated with hardy Ferns, which later, when the fronds develop fully, will clothe the ground. June may see similar places in the small garden gay with the purple and white flowers of the Foxglove or the scarlet and black Poppy, *Papaver commutatum* (*P. umbrosum*), which flowers in June from self-sown seeds.

Though very careful cultivation and attention are not necessary to obtain good results, a certain amount of attention is desirable. Foxgloves, Honesty, Forget-me-nots, Poppies, *Impatiens Roylei* and *Mimulus luteus* all shed their seeds and come up freely in the autumn or following spring; but weeds also grow just as freely, and must be kept down and prevented from seeding. The ground, however, neither of necessity nor to

of Foxglove or *Myosotis* instead of grass, and then, after a year or two, if not thought desirable to be continued, allowed to lapse and become part of the woodland grass.

To obtain material to extend this style of gardening, seeds may be sown where they are to flower, or there is usually plenty of young plants in the existing groups which may be transplanted from autumn to spring. In forming these masses or stretches of flowers, avoid any formal lines and curves. Let them naturally coincide with, or fit in with, the surrounding trees and shrubs and the lie of the ground, taking every advantage of sloping or hollow ground. A. O.

RARE SHRUBS AND TREES AT ALDENHAM HOUSE.

In a recent walk round the gardens at Aldenham House with the Hon. Vicary Gibbs and his accomplished head-gardener, I saw several interesting shrubs in full beauty. I was particularly struck with the magnificent Cherry (*Prunus Pseudocerasus*) *Shirofugen*, which was perfectly charming with its long, horizontal branches laden with huge double, blush-coloured flowers. This variety blooms more freely, if anything, than James H. Veitch, and the flowers are larger; the colour is several tones lighter.

Another magnificent object was that glorious Sycamore, *Acer Pseudoplatanus* *Prinz Handjery*, a young standard tree of which was exquisite in its early garb of bronzy salmon, that shone with a burnished lustre in the spring sun. *Prunus Rhexii* *flore pleno*, laden with its double white rosettes, was very beautiful. *Rubus deliciosus*, here grown as an open bush and pruned hard after flowering, has large pure white flowers, like great single Roses, and, though common, is one of the most chastely beautiful plants in the whole collection. A splendid plant of *Pittosporum tenuifolium*, much at home on the dense clay, is an object-lesson to those who doubt the hardiness of the genus. I have not heard of this species in the famous collection at Castlewellan. The small flowers are almost black.

Of the numerous Japanese Quinces, *Pyrus japonica* *Simonii* and *Maulei perfecta* were two of the best; the former has magnificent colour—a rich blood crimson. The Purple Nut (*Corylus maxima atropurpurea*), with its dense mass of burnished purple foliage, is a splendid foil for *Acer Negundo variegatum* and other light-leaved subjects. The Nut is cut hard down every three years.

The names of interesting things beautiful in flower or foliage would make a long list. *Cotoneaster Dammeri*, a grand rock creeper; *C. multiflora* and many others; *Ribes laurifolium*, *R. speciosum*, *R. leptantha* (evergreen) and others; *Stranvæsia undulata*, a host of Barberries, the lovely *Exochorda Giraldui*, *Spiræa lævigata*, resembling the Spurge Laurel; the silvery *Pyrus salicifolia pendula*, the golden *P. Aria chrysophylla*, the large-leaved *Prunus Avium decumana*, the graceful *Prunus Padus Albertii*, with long, white lilac-like spikes; the dwarf *pumila* and the

A BEAUTIFUL WOODLAND SCENE: FORGET-ME-NOTS WITH A BACKGROUND OF DARK CONIFERS.

surroundings are essential, and another very important point is the effect at a distance. The accompanying illustration, for instance, depicts the beautiful blue Forget-me-not, *Myosotis alpestris*, growing on the side of a slope where it can be seen a long way off. Looking out from the upper windows of a dwelling-house and seeing an effect such as this, perhaps some distance off, across the lawn on the edge of the woodland, when the blinds are drawn up on a May morning, must command admiration.

In a somewhat similar manner masses of such things appeal to most visitors to public parks and gardens. Though such effects as that depicted in the illustration are only possible in gardens of considerable size, both Foxgloves, Honesty and Forget-me-nots can be effectively used in the shrubby borders and other corners of the small

destroy the natural character of the planting, needs to be kept as rigidly clean and free from weeds as the flower-beds and herbaceous borders. The young plants, in many instances, may come up irregularly, necessitating thinning, though this should not be done too rigidly and evenly, or the plants, when in flower, may resemble a well-kept bed, instead of apparently a stretch of natural wild flowers. For these large patches it is as well to dig over the ground and, if poor, manure it in the first instance previous to sowing. It is also worth while every third or fourth year lifting the seedlings in autumn, digging the ground and replanting.

In addition to what may be termed the large permanent patches, a few supplementary patches crop up from time to time. For instance, when clearing out old shrubs or cutting down trees in the woods, the bare ground may be sown with seeds

variable *P. Pissardii* Hessei; that fine Beech, *Fagus sylvatica* Sweet Magnet; the Chestnuts, *Esculus sylvatica* Hessei, *indica* and *turbinata*; *Lonicera Heckrottii*, not yet in bloom; the winged *Euonymus*, *E. alatus*, which is rose-tinted in autumn; *Drimys Winteri*, with its large oval leaf and brown stem; *Nothofagus obliqua* (the Chilean Pine), *Fraxinus Mariesii*, which Mr. Vicary Gibbs considers to be the best of the *Ornus* type; *Robinia crispera* and *tortuosa*, varieties of *Pseudacacia*—all these were well represented. Add to them such uncommon things as *Stephanandra Tanahae*, *Coriaria japonica*, *Ligustrum Weidmanii*, *tricolor* and *coriaceum*, *Viburnum Carlesii*, *Castanopsis chrysophylla*, *Shepherdia argentea*, *Broussonetia papyrifera cucullata*, *Syringa Emodi*, *Veronica canterburyana*, *Corylus avellana aurea*, *Acer campestre Schwebleri*, *Ilex cornuta* and *I. dipyrena*, *Bupleurum fruticosum*, *Baccharis patagonica* and *Cratogeomys Dardari* (a graft hybrid), and an idea is gained of the interest, variety and beauty of the collection.

One cannot fail to be struck by the splendid culture and skilful grouping, nor by the complete mastery which the Hon. Vicary Gibbs displays of his many acres of beautiful and rare shrubs and trees.

W. P. W.

A BEAUTIFUL AUSTRALIAN SHRUB.

(*ELÆOCARPUS RETICULATUS*.)

It is well over a hundred years ago since *Elæocarpus reticulatus* was introduced from Australia. It was then known as *E. cyanus*, by which name it is still often referred to. At the time when hard-wooded plants of Australia were at their height of popularity in this country, *E. reticulatus* was one of the most widely cultivated. To-day it is rarely seen, although by virtue of its delicately-fringed white flowers it is worthy of far wider cultivation as a greenhouse shrub. If given sufficient room, it is a plant that will attain a height of from 12 feet to 15 feet, but it is a simple matter to have plants in full flower although only as many inches in height. For instance, the illustration, which so well depicts the character of the fringed, bell-like flowers, represents an entire plant that has been knocked out of a 3-inch pot for the purpose of photographing. The value of these little plants—easily procured from cuttings—can hardly be over-estimated. For table decoration and for conservatory work, especially where small plants are required as edgings to groups, such plants are invaluable. The cuttings, it should be explained, are made from the ripened shoots with leaves intact, and placed in sandy soil with bottom-heat. Propagation may also be effected from seed if sown in a hot-bed. June and July are the usual flowering months, and the beautifully-fringed flowers are followed by globose blue fruits, or drupes as they are botanically termed

THE FLOWER GARDEN.

SEASONABLE NOTES ON CARNATIONS.

THE month of July brings a plethora of beauty in the garden, for it is then that the Roses, the Carnations and the Sweet Peas reach the summit of their beauty, and it is a time that must be prepared for in advance. To secure the utmost delight from the occupants of the garden, they must be so well managed that they grow to perfection, and no plants will do this when they are neglected or if it is thought that necessary attention can be

presence is generally easily discernible, whereas the thrips hide themselves cleverly, and in the absence of diligent search may do irreparable injury. For the green fly there are many excellent washes advertised in *THE GARDEN*, or soft soap and Quassia wash may be prepared at home. One dressing may not suffice, but two or three will put things straight. For thrips Abol is reliable, prepared according to the makers' clear instructions, but the enemy should also be sought for and immediately killed.

Hoing and Mulching.—When either of these operations is decided upon, the grower has one chief idea in his mind—he desires to keep the soil cool and moist. By hoeing alone the moisture may be conserved in the soil to a pronounced extent; but when the hoeing is supplemented by mulching, the end in view is attained, and, at the same time, food that will undoubtedly be appreciated is provided for the plants. For these reasons hoeing ought to be done, and afterwards a covering of manure should be spread over the whole surface. If the appearance of it is strenuously objected to, spread above it a thin coating of the finest mould, but for preference leave it exposed to the air.

Disbudding.—Carnations grown purely and simply for the adornment of the garden and for cutting are not always disbudded, but this can only be regarded as an error of judgment. When a plant is producing so many blossom-buds that it is impossible for any of them to develop in perfection, reduction must be the rule, because a flower that is not perfect cannot adequately fulfil its mission. It is affirmed by some people that disbudding is contrary to Nature, and they will not have recourse to it; but this is a poor argument, since if it were followed out to its logical conclusion we should see no improvements upon Nature's admirable handiwork. By all means reduce the number of buds on a stem according to judgment or fancy, and do not permit all to remain when the plant obviously lacks the power to finish them. For individual exhibition blooms the reduction is carried to the crown bud, but for home service two or three buds can always be desirably retained, and the results will be more pleasing.

Flower-Stems.—We must also give careful consideration to the flower-stems, which are not usually strong enough to carry their flowers in a favourable position. Here there is not the slightest doubt that Nature must be followed, and the method of placing a stick in each pot and drawing all stems in a mass round it is strongly to be condemned, because by so doing the attractive habit of the plant is entirely destroyed. One stick, one plant, is by no means a bad rule, but there must be no bunching; on the contrary, each stem should be in a separate strand of tying material in such a manner that its grace may be appreciated and its flowers seen. Slender green sticks of sufficient length to go deeply into the soil and so

ELÆOCARPUS RETICULATUS, AN AUSTRALIAN SHRUB WITH BEAUTIFULLY FRINGED WHITE FLOWERS.

given at any time or any moment. The successful gardener looks far ahead, and this month he will be laying the final foundation for the glories of July among the flowers.

Insect Enemies.—The enthusiast in Carnation culture rests happy in the knowledge that his favourites of the bed and border are not particularly prone to the attacks of many insect pests, but those which give the plants attention will quickly do harm unless they are suppressed. A persistent look-out ought to be maintained now for the visitations of green fly and thrips. The first named increases more rapidly than the second named; but it is, all things considered, easier to deal with and more readily discoverable. Its

secure a firm grip are excellent, while there are special supports on the market for these plants. From the one stuck green bast or very soft green string will provide efficient support.

NOTES FROM WISLEY.

ONE can never visit the Royal Horticultural Society's Gardens without learning some useful lessons. Just now in the wilder part there are two or three regions of special beauty, where masses of perennial Lupines and Columbines are happily grouped with a shrubby background. Both kinds of plants are in many tints of purple, pink, and white, the colours blending delightfully not only with each other, but with those of the Lilacs and Rhododendrons at the back. Both the Lupines and Columbines seed so freely that a large stock can easily be raised, and nothing can be better for the decoration of any rough or otherwise waste place, such as so often occurs on the outskirts of a garden.

Tree Lupines are grown as standards with large, shapely heads, a mass of bloom, on a trunk about four feet high. With careful pruning these standards are no doubt kept in good order for several years, the pruning much prolonging the life of this usually short-lived plant. G. J.

THE SNAPDRAGON AND ITS CULTIVATION.

THE Antirrhinum, popularly known as the Snapdragon, is one of the few flowers which will thrive under almost any conditions, and often under the most adverse. It will blossom in profusion on the arid heights of the battlements of some old castle or ruin, and will equally luxuriate in the herbaceous border of a well-kept garden. That such an accommodating and beautiful flower should have evaded the notice of seedsmen for so long is surprising; but during the past few years several of our leading growers, having seen its

about the end of May. The plants are in blossom by August, often earlier, and flower away right into late autumn. Moreover, the Antirrhinum is not tender, and if left unpruned it will withstand the winter and break into new growth in early spring, carrying large masses of flowers in May the following year. In the hands of the raiser it has proved its adaptability to various heights, and we have the same colours and forms in the dwarf (Tom Thumb), the intermediate (nanum) and the tall (majus) varieties. Thus the Antirrhinum lends itself to all manner of arrangement in the hands of an artistic grower, and some wonderful colour effects can be obtained by judicious selection.

As a Greenhouse Plant.—For indoor work, the greenhouse and conservatory the Antirrhinum is equally useful. Given cool treatment throughout and careful attention, magnificent spikes can be obtained. It is absolutely essential that the grower keeps the conservatory free of bees, which would prove fatal to his flowers. A house of Antirrhinums thus protected will retain the lower flowers until the whole spike is expanded. A few days ago it was the writer's good fortune to be in the neighbourhood of Mark's Tey, and a visit was paid to the seed farm of Messrs. Dobbie and Co. Naturally, after the display of Sweet Peas shown at Chelsea at the recent show, one was interested in Sweet Peas, but it is no exaggeration to say that the Sweet Peas were totally eclipsed by the house of Antirrhinums, some of which blossoms were to be shown at the Royal Horticultural Society's Show on Tuesday, June 3. Every form was there. On one side was a batch of Tom Thumb Dobbie's Brilliant, each in a 4½-inch pot, carrying six spikes of superb flowers. Next to it stood a batch of Dobbie's White Beauty, without the slightest trace of yellow in it. A batch of coccinea was a dazzling mass of brightness, and the striped varieties gave every variation that the most fastidious could wish, while Yellow Queen was unsurpassed. Of the majus variety. I measured plants bearing three spikes with twenty-

A CARPET OF MOSSY SAXIFRAGES IN THE ROCK GARDEN.

Primula japonica, in great profusion by the water-side and in cool, damp places under the shade of Oaks, has broken into a number of tints, from the type magenta crimson to a nearly pure white. The type colour is to me, and to many, an unpleasant one, and it is a pleasure to see that in some of the later crimson seedlings the colour is tending to a much better kind of red, such as gives a hope of ultimate arrival at a good scarlet crimson or blood red.

Rambler Roses.—An excellent way of growing the strong rambling Roses is practised at the Royal Horticultural Society's Gardens. Three stout Larch poles, about eleven feet out of the ground, are placed triangularly about two feet six inches apart at the butt, and are brought together at the top. Outside the foot of each pole a Rose is planted. The three of the same kind meeting above form a large and handsome Rose pillar.

potentialities, have given it careful attention, with the result that there are now on the market some of the most magnificent varieties. This flower is deservedly becoming popular, and for many years to come will be in the forefront of the hardy border flowers. Thanks, too, to the perfection with which the several growers have carried out the selecting of seed, it is almost needless to grow named varieties, except for special purposes, as the seedlings raised year by year are equally as good, and of necessity grow more vigorously than plants from cuttings.

Culture.—Antirrhinum seed should be sown in cold frames or outside in summer, pricked off, and then transplanted into permanent quarters to flower the following season from May onwards; or a plan the writer prefers is to sow seed in pans in a steady heat in February, transplant into frames in April, gradually harden, and plant out into good, rich soil in clumps 1 foot between plant and plant

eight expanded flowers and some twenty more unopened to each spike, and the plants were almost five feet in height. The length of the flowering spikes varied from 18 inches to 24 inches. Cottage Maid, Moonlight, coccinea, Crimson King and White Queen were varieties specially strong and vigorous in growth, carrying immense spikes of finely-developed flowers. The bees had been rigidly excluded from the house, and, although the lower flowers were paler than the newly-opened blossoms, yet the spikes were entire, and the whole display of hundreds of pots of well-grown plants was a grand triumph of the gardener's skill. Truly the Snapdragon is a most accommodating garden flower, but it is not generally known to what good effect the Tom Thumb varieties may be grown in the rock garden. The Antirrhinum has come to stay, and will reign as one of the monarchs of free-flowering hardy plants for many years to come.

S. W.

ROCK AND WATER GARDEN.

MOSSY SAXIFRAGAS FOR MASSING.

TOWARDS the end of May and in early June one of the most effective features in a well-furnished rock garden are the masses of various kinds of Mossy Saxifragas covered with sheets of white and rose coloured flowers. During the rest of the year they form carpets and mounds of emerald green foliage that are very attractive, one of the loveliest features in the rock garden during the past winter being a sloping bank of the Dovedale Moss (*S. hypnoides*), forming a close and compact carpet. For a cool and partly-shaded bank there is no more useful plant than the Mossy Saxifraga, for it is one of the easiest plants to grow. They all like a light rich soil and a position where they will not get dry and be burnt up in the summer. An ideal place is on a northern slope that is not too steep, where the plants themselves get the benefit of the sun but the ground is shaded and cool. The Mossy kinds may be propagated by dividing the plants after they have done flowering, taking care to keep some roots with each piece. They should then be planted in some shady border where they can be well watered for a time, till the plants begin to form new roots. In the autumn they will be ready for planting in their permanent quarters for flowering in spring. To obtain large, unbroken masses, the plants should be allowed to grow together, and then remain undisturbed. Young plants may also be produced from seeds; but as the Saxifragas so freely hybridise, they cannot be relied upon to come true. Cuttings during the summer months is another method of increase. These should be selected from the young growths that are made after the plant has finished flowering, and should be inserted in sandy soil in a close frame. The species of Saxifragas are very numerous, and many of them are very similar in appearance. Those mentioned here are some of the most distinct and useful for general purposes.

S. cæspitosa is one of the commonest Mossy kinds found in our gardens, where it is grown under many names. It is found on some of our highest mountains, and forms tufts of bright green foliage. It is a very free grower, and produces its large white flowers on branching stems some 8 inches or so high.

S. canaliculata, a native of Spain, belongs to the dactyloides group, which have very distinct divided foliage. It quickly grows into large tufts, and produces its white flowers freely.

S. decipiens.—This is very closely allied to *S. cæspitosa*, and many of its forms cannot be distinguished from that plant. Of it there are numerous varieties, while, by hybridising, many

beautiful forms have been obtained. The red colour in this section was first obtained by crossing this and other kinds with *S. muscoides* variety *atropurpurea*. Then by selection and continuous seeding, such beautiful plants as *S. d.* variety *grandiflora*, *S. bathoniensis* and *S. sanguinea superba*, all with red flowers, have been obtained. One of the first, and still unsurpassed for neatness of habit and brilliant colouring, is Guildford Seedling. It forms a very compact carpet, and the bright red flowers are on stalks only a few inches high.

S. exarata.—On page 302 a group of this may be seen on the right, with flowers so thickly

forms a fitting and charming groundwork for early spring-flowering bulbs when they are in flower. On a cool, shady bank it will form a close carpet covered with a mass of snow white flowers in spring. For spring bedding or edgings for the front of the herbaceous border it is excellent. There are numerous varieties of the Dovedale Moss, of which the most compact are the varieties *genmifera* and *Kingii*. *S. h. variegata* is a prettily-variegated form.

S. maweana is one of the largest-flowering kinds in this section, with distinct rosettes of foliage. In some places, however, this plant does not stand our winters well.

S. muscoides is a pretty dwarf carpeting plant with yellowish flowers. It forms a turf-like mass of tiny rosettes that make a very pleasing object in the winter. One of the prettiest forms, and the origin of all the colour varieties that we have in our gardens belonging to this section is *S. m. atropurpurea*, a very dwarf, moss-like plant, with rosy purple flowers on stems about an inch or two inches high. *S. m. moschata* is a larger variety, with yellowish white flowers.

S. pedemontana is one of the stronger-growing kinds, with rosettes of broader foliage. The three-lobed leaves are very distinct and bright green in colour, while the white flowers are borne in freely-branched corymbs.

S. sponhemica is closely allied to *S. cæspitosa*, with more finely-divided leaves in smaller rosettes. It is a quick grower, and seeds itself freely about the rock garden.

S. trifurcata.—Probably one of the most distinct kinds belonging to the Mossy section, with rosettes of three-parted leaves and white flowers in elegant panicles. The Stag's-horn Rockfoil (*S. t. ceratophylla*) has rather more divided leaves, much stiffer in texture, and forming a firm cushion of rather glaucous foliage. It is an old inhabitant of our gardens, having been in cultivation for over a century.

S. Wallacei.—This garden hybrid has been confused with the Spanish *S. Canposii*, but is more hairy and of freer habit than that plant. It is one of the most popular plants for spring bedding, with its freely-produced, large white flowers, which possess a Hawthorn-like scent. Very closely allied to

produced that they form a solid mass. The stems are very thickly produced, and branch so freely that there are several layers of flowers, one on the top of the other. Individually, they are small and white, commencing to flower early in May, and continuing well through the month of June. A square yard of this plant in flower is a remarkable sight, and, like all the others during the rest of the year, forms a cool green carpet of foliage.

S. hypnoides.—Of all the Mossy kinds, perhaps the Dovedale Moss is the most popular. It may be used in many ways and for many purposes. Planted in small tufts some few inches apart, it

this, but with rather smaller flowers, is *S. glaucescens*, which is shown in the illustration on the left. Both are excellent growers, easy to increase, and of compact habit.

During the past few years many hybrids and seedlings of varying merit have been brought out. Some, like *Lady Deane*, have very large flowers, but they lack the refinement and elegant habit of many of the wild types and selected varieties. **W. I.**

PRIMULA PSEUDO-SIKKIMENSIS, A BOLD PLANT WITH PALE YELLOW FLOWERS.

PRIMULA PSEUDO-SIKKIMENSIS.

PROBABLY no *Primula* is worthy of greater admiration than the graceful *P. sikkimensis*, or the

Himalayan Cowslip as it is sometimes aptly called. It is said to be the pride of all the Primulas of the mountains of India, inhabiting wet, boggy localities at an elevation of from 12,000 feet to 17,000 feet, and covering acres of ground with its yellow, drooping flowers.

There is in the rock garden at Kew at the present time a number of Primulas flowering so freely that they cannot fail to attract the attention of visitors. These plants bear the name of *P. pseudo-sikkimensis*, but in what manner this plant differs from the true *sikkimensis* it is not easy to define, except that it is a native of China, stronger in constitution and of more robust habit. The colour and form of the flowers are identical with those of *P. sikkimensis*. The new-comer may therefore be regarded as the Chinese representative of the Himalayan Cowslip. Probably the name *pseudo-sikkimensis* will never be in general use. The two forms are so much alike that they will doubtless both be called by the same name, *sikkimensis*, which, after all, seems the most satisfactory plan, for without doubt they are geographical forms of the same species. It goes without saying that the culture for both is alike. Both are hardy and love a deep, well-drained, but moist soil and a shady place. The leaves disappear in the winter, and during the time that the plants remain dormant they should not be molested or overlooked. Propagation is effected by division in spring or autumn, or by seed sown as soon as it is ripe.

CAMPANULA PUMILA AND ITS VARIETIES.

To the general cultivator of rock plants the differences between the plants covered by such names as *C. pumila*, *C. pusilla*, *C. cæspitosa*, *C. cochliariæfolia* and others seems to be of an infinitesimal character, and most of us are content to take the plants as simply forms of *C. pumila* or *pusilla*. With all deference to authorities, for all garden purposes the names may be taken as the same. There are, however, differences in size of flower, and also in shade of colour, among these little flowers. I am confident, for example, that there are two or three white forms, differing mainly in size of flower, better form of the bell, or greater substance in the bloom. At one time one was disposed to think that these were produced by the character of the soil, but actual experiment has made one think otherwise. My own old white one has been in my possession for many years, but it is inferior to one I got from Mr. Platt's garden at Hyning, and I came across another superior form in a local garden recently. In the case of the blues there are certainly differences in the size and form of the blooms, as well as in the colour. Opinions seem to vary as regards the shade of the one called Miss Willmott, yet it appeals to some eyes. But the greater number of the blue varieties

of *C. pumila* lack depth and not lightness of colouring, and what I would like would be a real dark purple blue, one of, say, the shade of *C. Hostii*. As an edging, as well as for masses on the rockery, *C. pumila* is such a lovely thing in all its colours that we can hardly have too much of it.

S. ARNOTT.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Papaver Perry's Unique.—A plant of moderate growth and distinct. The colour is brilliant

and coloured a soft yellow, with a suspicion of buff, the bases of the petals crimson; there is a tuit of golden yellow anthers. We regard it as an acquisition. It gives us the impression of a semi-double *La Lorraine*, which gained a first-class certificate on May 14 last. From Messrs. Kelway and Sons, Langport. See illustration.

Primula × Excelsior (*P. cockburniana* × *P. Unique*).—The fact that this unique hybrid has already proved itself both a true perennial and quite hardy starts it on its career with a reputation of its own. At the present time the new-comer possesses all the vigour and free-flowering attributes of a glorified *P. Unique*, and, with handsome flowers of a brilliant crimson-scarlet, needs little further to commend it. A really first-class plant and an acquisition. From Messrs. James Veitch and Sons, Limited, Chelsea.

Salix magnifica.—A plant as it were much unlike a *Salix* as it were possible to be from the leaves alone was shown by the Hon. Vicary Gibbs, Elstree, under this name. The leaves are broadly ovate-acuminate, and are some 6 inches or 8 inches long and 3 inches to 4 inches broad. It is a new Chinese species.

Potentilla Boule de Feu.—Said to have been raised between *P. argrophylla* and *P. atrosanguinea*. The flowers, which are coloured crimson-scarlet, are about an inch across. The foliage is silvery, after the manner of the first-named species. From Mr. H. Hemsley, Crawley.

Iris gracilipes.—The flowers of this pretty Japanese kind are of palest mauve, with an orange blotch, and in this and their fringed character may be likened to a miniature *I. tectorum*. The grassy, arching leaves are numerous produced, though the plant has not so far proved very floriferous. At the same time, there is a frail and delicate beauty about it which all lovers of the genus admire. From the Wargrave Plant Farm, Twyford.

Delphinium Mrs. F. Brewster. Only a solitary spike of this was shown, and that not of high excellence. The clear lilac mauve flowers are, however, distinct, and of large size. Exhibited by Mr. R. C. Notcutt, Woodbridge.

NEW ORCHIDS.

Awards of merit were granted to three new *Odontoglossum* hybrids, viz., *O. Aireworthii* Orchid Dene variety (crispum blotched form × *lanbeauianum*), from Mr. E. H. Davidson, Twyford; *O. Lairessei* (*Edwardii* × *Cervantesii*), from Sir Trevor Lawrence; and *O. Neptune* (*crispum* × *nebulosum*), sent by M. H. Graire, Amiens.

The foregoing awards were made by the Royal Horticultural Society on June 3.

THE NEW PÆONIA ARBOREA L'ESPERANCE, A REMARKABLE YELLOW FLOWERING VARIETY WITH A CRIMSON BASE.

crimson-scarlet, the black-blotched petals being lacerated to nearly one-half their depth. From Mr. Amos Perry, Enfield.

Stachys corsica.—A pretty green carpeter of the soil, preferably in cool and moist places. The half-inch-high flowers are pure white, the plants when in good condition being freely studded with them. From Messrs. R. W. Wallace and Co., Colchester.

Pæonia arborea L'Esperance.—A remarkable and beautiful addition to the Tree or Moutan Pæonies, and a variety, when plentiful, destined for great popularity. The flower is semi-double

GARDENING FOR BEGINNERS.

THE PEAR MIDGE.

THIS is one of the most troublesome pests of the garden, and certainly one of the most difficult to stamp out when once it has established itself. The mischief is done at a time when it is impossible to spray the tree with any hope of destroying the insect without also injury to the fruit and trees.

It is necessary to understand something of the life-history of this pest before we can deal effectively with it.

The female insect (Fig. 1) is a minute creature with great power of flight, which appears just as the Pear trees are about to open their flower-buds; she pierces a hole through the petals and lays eggs to the number of ten or more. I have frequently counted twelve grubs in a fruit. These grubs (Fig. 2) feed on the small fruit, causing it to become deformed. It will be at once understood how useless it is to spray trees with a hope of killing these grubs without at the same time destroying the young and tender fruit also. Again, winter dressing and spraying do very little, if any, good, as the grubs bury themselves deeply in the ground for some weeks before they form a cocoon, in which state they pass the winter. It was a long time before I could understand what was wrong with the Pear trees in this garden. They flowered and set fruit abundantly; but each year, towards the middle to the end of June, most of the fruit invariably fell from the trees. I noticed, however, that these small fruits were malformed, as in Fig. 3, and on cutting some of these open I discovered a quantity of small yellow grubs, which had entirely eaten away the middle of each fruit, causing it to fall, and on examining the fruits still left on the trees I soon discovered those affected, owing to the malformation above mentioned. I then carefully examined each fruit, and any which showed the least deformity I at once gathered and buried. The beginning of June is the best time to do this. The trees affected should be examined each day and the fruits gathered; they should not be allowed to fall from the tree, as the grubs will leave the fruits as soon as they fall and bury themselves in the soil, where they will be quite safe from birds or other enemies.

I have seen spraying recommended as soon as the flowering period is past. I believe this to be useless. Several years I persevered with this, using many kinds of insecticides, with no good results. Hand picking is the only reliable measure to adopt, and this should be persevered with daily if this scourge is to be got rid of entirely. From what I hear, it is certainly increasing in many parts

of England, and it is one of the most difficult insects to eradicate I ever encountered. I believe some good may be done in winter by forking the soil about the stem of the trees to a depth of 8 inches; in this way some of the cocoons may be destroyed. I am sorry to say that I had no difficulty in finding material from which to make the sketches. It would also seem that certain varieties of Pears are attacked more freely than others; Emile d'Heyst, Clapp's Favourite and Doyenné du Commerce seem to be special favourites. No vegetation should be allowed to grow near the trees, as this affords a hiding

place for the grubs after leaving the fallen fruit freely, even when they receive very ordinary treatment; but if they are given the very best treatment the fruits are finer individually, of better flavour, and the crop is heavier. At the present time the cultivator should examine the plants and duly note those that are small and weak and not likely to be of service next year. Remove all such forthwith. If left they only cause overcrowding, blocking out both sunshine and air from the stronger canes which will be retained. Renew the half littery mulch of manure now, and, directly the fruit is gathered, do the final thinning out of surplus canes. Too much stress cannot be laid upon the importance of pruning after the fruit is gathered. The work is rarely done before the autumn or winter, and it is a very harmful and unnecessary delay.

Well-Rooted Plants may be fed regularly now, and those specimens growing in rather small pots should have a surface mulch of good fibrous loam (first soaking it for twelve hours in strong manure-water), a small quantity of leaf-soil and some sharp sand. This mixture may also be applied with great benefit to plants growing in borders. All well-rooted plants must be fed freely with weak and frequent doses of manure-water, and that in addition to any surface mulch that may be put on. Clear water must be given twice, and in very hot weather three times a day, to prevent the loss of foliage, but the cultivator must make sure that the drainage is sound.

Overcrowding and Tying.—The regular tying in of the shoots of climbers—especially those of the Stephanotis—is a very important matter. The very weakly ones must be cut out, and the others trained thinly to the wires.

Shading and Ventilating.—If the cultivator is experienced, he will not do much shading, but the novice should shade his fine-folaged plants a little to prevent the lovely leaves being scorched. While the weather is fine admit plenty of air from early in the morning until four o'clock in the afternoon, and when closing the house syringe and damp down freely. SHAMROCK.

THE PEAR MIDGE AT VARIOUS STAGES.

1. Fully-developed fly.

3. Deformed fruit.
4. Grubs inside the fruit.
5. A perfect fruit.

place for the grubs after leaving the fallen fruit.

A. T.

STOVE PLANTS.

MANY young gardeners and others who have had no opportunity to gain experience about the management of stove plants—those grown in a rather high temperature and moist atmosphere—are suddenly called upon to undertake a charge including a number of such plants. In the winter they are not very difficult to manage if the requisite heat is maintained and watering is not overdone. At the present time, however, young shoots are growing so freely and flowers are appearing in such profusion, while the richly-coloured leaved kinds are making much progress, that any neglect in regard to the plants may soon

cause them to deteriorate to an alarming extent. The Allamanda, Stephanotis, Dipladenia, Clerodendron and Bougainvillea are all very beautiful flowering plants, while the Croton and Caladium are a pair of most beautiful, fine-foliated kinds.

B.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Dahlias.—These should now be planted, and if in large beds on the lawn, care must be taken in the selection of varieties and their various heights. The dwarfier, stiff-stemmed varieties are much the best for beds, and certainly many of the Pompon and named singles are to be preferred to the pendulous-flowered Cactus varieties. Staking is very essential immediately after planting, though for a week or two it may not be necessary to put the permanent stakes in, especially if the plants happen to be in a prominent position.

Rhododendrons and Azaleas.—These having passed out of bloom, the seed-pods should be carefully removed to concentrate the energy of the plants on the young growing shoots as well as for the sake of tidiness.

Planting Annuals.—A showery time should, if possible, be selected for getting all annuals planted out that have been raised in frames and boxes, and good breadths of the various kinds for cutting may with advantage be planted in the kitchen garden, this being preferable to denuding the borders in and about the pleasure grounds.

Sweet Peas.—These from early sowings are nicely in bloom, and a little assistance may be necessary in the form of liquid manure, or even artificial, once a week to maintain them in vigorous growth. On light soils a mulching of short manure and leaf-soil will help to conserve the moisture, while on soils of a heavier nature the hoe is one of the best mediums. Sweet Peas for exhibition must be kept regularly tied, and if the plants are not so strong as desired, remove the flower-buds for a little while, but not if they are intended for early July shows, as it takes from fourteen to twenty-one days for a bud to open after its first appearance. Syringe overhead in the evenings after very hot days.

The Rose Garden.

Watering.—Should the weather be at all dry, a copious watering or two with liquid manure will now greatly help Roses, giving the surface of the soil a good hoeing over as soon as the water has nicely soaked in.

Aphis at this season is especially troublesome, and a good wash overhead with the hose once or twice a week will help to keep it down. About this date, also, the plants should have a good spraying with an insecticide, for as soon as the flower-buds commence to open they are liable to injury, at least the outer petals may be marked, so an effort should be made to get the plants clean before they become too forward.

Maiden Plants, both standards and dwarfs, must be regularly tied to stakes to prevent them being blown out, there being more danger now that the foliage is getting heavier.

Plants Under Glass.

Annuals in Pots.—There are several kinds of annuals, such as Asters, Stocks, Salpiglossis, Larkspurs, Coreopsis, Statice, Alonsoa and Chrysanthemums, that are very useful in pots, particularly where there is a big demand for pot plants for the conservatory. These may now be lifted from the beds in which they have been pricked out, with nice balls of soil, and potted singly in 4½-inch pots, or perhaps three in a 6-inch pot. If placed in a frame and given a little shade for a few days, they will soon get over the check, and with very little trouble other than watering they will make a nice display.

Salvias may now be potted into their flowering pots and stood out on a nice open piece of ground. Keep the shoots pinched fairly close till the plants are of sufficient dimensions. A little later in the season the pots may be partly plunged in ashes. This will lessen the watering somewhat, and considerably increase the size and appearance of the plants.

Hydrangeas. Early batches of Hydrangeas that have been flowered in 4½-inch pots should be cut down to within 3 inches or 4 inches of the tops of the pots and stood in an open position in frames or other places, where they will soon break freely, and if potted on, when the shoots are 3 inches or 4 inches long, into 8½-inch pots they will make

good plants with six to eight heads for next season, and may be flowered very early.

The Kitchen Garden.

Early Celery will now be forward enough to plant in the trenches, or, in the case of that which may be wanted for exhibition purposes, on the flat with plenty of good short manure underneath the plants. If they hit with good balls of soil and are planted firmly, a good watering will be sufficient to keep them going, though if the growth flags badly, as it will sometimes if it is soft and attenuated, a syringing or two for a few days may be necessary to give the plants a good start.

Onions.—Keep the soil well moved with the hoe, and autumn-sown bulbs that are swelling nicely may be assisted with a little artificial or a good watering with liquid manure about every two or three weeks. Thin the spring-sown Onions as soon as large enough to handle properly, having them from 4 inches to 8 inches apart, according to the size of bulbs required.

Tomatoes.—If not already planted, these should be put out at once, and if the plants are a good size they will soon grow away. A warm position is essential, as also is good firm planting.

Brussels Sprouts and other Brassicas should be planted out as opportunity occurs, choosing, if possible, a showery time, when the plants need a good deal less attention afterwards.

Chicory.—This should now be sown on a fairly light and rich piece of ground in drills about eighteen inches apart, thinning the plants to about eight inches or ten inches apart when well through the ground, and, should the weather be showery, while the plants are in a young state dust frequently with soot to prevent the ravages of Slugs.

Fruits Under Glass.

Ripe Grapes.—The houses in which ripe Grapes are hanging must be freely ventilated, and only sufficient moisture used in the houses to keep down insect pests. To preserve the colour in black Grapes it may be necessary to shade slightly, but this only in the event of very hot weather.

Pot Peaches and Nectarines from which the fruit has been gathered should be stood on an ash-bed out of doors, giving sufficient room between them to allow the free use of the syringe or garden engine. A little straw or litter may be placed among the pots to prevent them drying out.

Hardy Fruits.

Cherries.—A sharp look-out must be kept for fly on the tips of the young growths, and, in evidence, the trees must be carefully sprayed. This operation may have to be repeated two or three times, especially if the trees are badly infested, and wherever possible give them a good wash down with the hose in the morning after applying the insecticide.

Plums also are subject to green fly, and the above remarks apply equally well. Cordon and trained trees may have the points of the growths removed, thus checking the fly and helping the fruit at the same time.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Cutting Over.—Under this heading I would remind readers that many early-flowering subjects have now ripened their foliage or flower-stems, and these should be cut over, as tidiness should be the order of the day. Such subjects include Snowdrops, Crocuses, Narcissi in variety, Crown Imperials and Doronicums.

Watering.—Although not a believer in a too frequent use of the watering-can, still, it has to be brought into use at times, and if a drought sets in, as it often does in June, recently-planted subjects especially may have to be artificially watered. If necessary, attend to the work in the late afternoon, and after the surface soil has dried sufficiently run the Dutch hoe through it. Of spring-planted subjects, Violas and Pansies are the most likely to suffer from drought.

The Rock Garden.

Propagating Pinks.—The fragrance of many species and varieties of the genus *Dianthus*

justifies the appellation of Dainty Flower given to it by the ancients, and some of the gems are to be found in the rock garden, as instance *D. alpinus*, *D. cæsius* (Cheddar Pink), *D. deltoides*, *D. neglectus* and *D. superbus*. Some can be raised from seed readily, but all can be propagated by cuttings at the present time. Prepare the cuttings or pipings as you would border Pinks, and insert them in pots of sandy soil, packed firmly, and then water through a fine rose. A rather shaded, dwarf pit or frame is invaluable to the owner of a rock garden, and here the pots should be placed, keeping them rather close and shaded until roots have been formed, when the plants should be gradually inured to more light and air preparatory to their being planted in September.

Plants Under Glass.

Herbaceous Calceolarias.—I like to sow these about the longest day, although some growers sow rather later. Make sure that you get a good strain of seed. Some firms are now aiming at selfs or bicolors with large flowers, and they are very effective; but the spotted type should not be elbowed out. Sow in well-drained pans of fine soil that has been watered two hours previous to sowing. Mix the seed carefully with some sand or very fine soil to ensure uniform dispersion of the seed. Do not cover the seed, or, at most, only give a dusting of very fine soil. Cover with a pane of glass, shade with white paper, and place in a cool frame. If the soil becomes at all dry, moisten by immersion. Closely watch the process of germination, and gradually admit air and light, but do not expose to draughts or to full sunlight.

Cinerarias.—Prick off into boxes of light, rich soil as soon as the first rough leaf is formed. Keep rather close for a few days after being pricked off, and maintain cool and moist conditions.

Perpetual Carnations.—Plants that are ready for it should be shifted on into 5-inch pots, using a mixture of good yellow loam, if at all available, with some sand, wood-ashes, dried sheep or cow manure and crushed bones. A sprinkling of soot over the drainage helps to keep out worms and serves as a welcome fertiliser to the plants.

Fruits Under Glass.

Second Thinning of Grapes.—Later crops will now be requiring second thinning. Where the first thinning has been well done, this is a light operation; still, the keenest expert cannot always forecast subsequent developments, and so second thinning is a necessity. Great care should be taken to avoid injuring the berries with the points of the scissors. Any shouldered requiring tying out should receive this attention before second thinning commences.

Watering Vines.—Moisture on the surface of the border is no criterion as to its condition 18 inches below the surface, and this must be determined from time to time by a soil-tester or common auger, and if found to be dry, a good watering must be given, and advantage may be taken of the operation to apply some fertiliser to assist in the process of swelling the crop.

The Hardy Fruit Garden.

Netting Small Fruit.—This work is absolutely necessary nowadays, and those who have not yet gone to the expense of wire netting must fall back on tanned netting, and the sooner it is in position the better; especially is this the case with Strawberries. Strands of wire across the break either way will keep the nets off the ground. Make sure that all is secure at the ground-line, as it is there where the birds look for a means of ingress. For Loganberries use the oldest net, as it will never do duty again.

The Vegetable Garden.

Peas.—If not already done, the last sowing for the season must now be made. Stake succession sowings as they are ready. Early crops in pod should have a dressing of nitrate of soda or soot in showery weather if possible.

Exhibition Leeks.—These will now be growing apace, and they should be provided with cardboard collars to assist in the process of blanching. Draw in a little earth from time to time, and at each earthing slightly raise the collar.

Vegetable Marrows.—As growth proceeds, the leading shoot should be pegged down to prevent injury from winds.

CHARLES COMFORT.

THE GREENHOUSE.

REPOTTING AURICULAS.

It has been the general practice for many years for Auricula-growers to repot their plants annually. This practice was not always looked upon favourably by growers a hundred or more years ago. Some of them advocated the leaving of full-sized plants undisturbed in their pots for a second year, giving additional top-dressings in summer and spring, instead of an entire change of soil as is usual among present-day cultivators. These old growers used pots for their full-sized plants much deeper and wider than are used now; and although we adopt a different practice from that followed by our forbears, we must pay some deference to their ideas, for these were born of the results of a certain measure of trial and experiment. Granted the experiments were not always conducted on the lines we think best, these old enthusiasts achieved results that, I think, would not in any way do discredit to our principal present-day exhibitors. They fixed a high standard to work to, and at their shows in London and district their plants had to have at least seven expanded pips. This rule would handicap some of us when show-day comes round and we are looking for plants for classes of twelve, eight, six, &c. The organisers of these old Auricula shows did not attempt the bold displays we see at our exhibitions, and had no classes for twelves and sixes as we have, but showed their edged flowers almost exclusively in pairs. Our bright and gloriously-coloured alpine were then non-existent. Competition was keen at these shows, and, as I have already said, the old growers fixed a high standard, a standard we have not seen fit to alter. This to our credit. These men of old times fixed the ideals of perfection and set us on the way to attain it; indeed, they got so far on the way themselves that some of their work has hardly been excelled. They raised the immediate predecessors of George Lightbody, Richard Headley and Lancashire Hero, grey-edged flowers that grace the show-boards of our exhibitions to-day.

I have wandered considerably from what I first spoke of; but allowing that these old growers knew something of what they were about, is it not possible that we, in trying to remedy some of their faults, may go too far in the opposite direction? I do not think it is necessary to be quite so severe in the treatment of the Auricula at repotting-time as is sometimes the case. I have heard of some who systematically wash off all soil from the roots; this appears to me to be too drastic a proceeding as a regular practice. Another point as regards the repotting is to be considered: At what time of the year is it best to repot—early or late? By early I mean May to the middle of June, and late, during August. This is a question often asked now, and was much discussed in the days that are gone. Personally, I prefer to pot early, and, if I could, I would have all mine completed before May is out.

The Best Soil.—What compost should be used to grow the plants in? It is not possible to say this or that mixture is the best. Some growers obtain excellent plants and blooms in one mixture, others in another. What is most certain is that good loam full of fibre is the sheet-anchor of all composts, and excellent results can be obtained in that alone if the loam is not too heavy and the drainage is satisfactory. I myself use a mixture of four parts fairly heavy loam, as full of fibre as

I can get, and not stacked more than about six months, one part decayed leaves (do not have these from near manufacturing towns, but get sweet leaf-mould from the country), and one part old hot-bed manure. I do not use sand to keep the soil open, but crushed oyster-shell, charcoal and old mortar instead. To these I add a good dusting of bone-meal and soot. It is well to prepare this a few weeks before required for use, and to have it regularly turned over to get the compost as sweet as possible. This latter point is not to be lost sight of. Whatever mixture is used as a potting medium, it must be, above all else, sweet and fresh. Now take the plant to be treated. If an old one, take off the soil sufficiently to enable the main root to be examined for any sign of decay. If any exists, cut clean away to sound growth, putting dry lime on the wound. Shorten the main root if long. If in any doubt as to whether to cut a piece off or not, it is a safe rule to always give the preference to the knife, for it is the upper portion of the main root from which the principal and most useful root-fibres will come, the lower portion gradually becoming of less use. Take off any offsets that may be attached; these, if large, to be potted singly in small pots; if small, to be put round the edge of a 4½-inch pot. If the plant is in a small pot, it can be transferred to a larger one, only taking a little of the soil from the old ball. Pots of 4½ inches in diameter need very rarely be exceeded. Quite large plants can be grown in this size. Take care to work the new soil well among the root-fibres of the plant. Whenever a plant is taken from a pot, the root aphid, which is nearly always in evidence, should be cleared away, either by brushing off with a medium stiff brush or by applying methylated spirit. If the pots used have been soaked in water prior to the plants being potted, and the soil used is in a properly moist condition, the plants will not require watering for two or three days if they are placed in a close frame shaded from the sun. Beware of excessive watering at this stage. Decay is often set up by too liberal applications of water, especially where the roots have been cut. Keep the plants close for a week or ten days after repotting. As they begin to get settled in the new soil, give air gradually until, at the end of a few weeks, the lights can be removed altogether; but always shade from bright sunshine and keep as cool as possible. On the north side of a wall or fence is a good place for the frames during the summer. G. J. S.

SOIL PURIFICATION IN GREENHOUSES.

THE question of soil purification in greenhouses now seems to be attaining more practical shape, and experiment has been busy with sterilisation as a means of ridding the soil of the unhealthy fungoid and other undesirable lower forms of life which undoubtedly cause much trouble to all who cultivate under glass. Tomatoes and Cucumbers are liable to many scourges when grown in this way, and it seems likely enough that the soil is largely responsible for this. Recent research has shown that sterilisation can effectively deal with the matter, and results similar to those in the case of sewage-sick soils have been obtained. Many substances, such as formaldehyde and toluene, have been tried, and it seems likely that a number are useful, and work on a commercial scale has been proved to be practicable. Heat is much the best remedy, but it is expensive—much more so than are chemicals, the alternative method. However, at 1s. or 1s. 6d. per ton of earth purified, it

seems that heat is applicable to Cucumbers, Tomatoes in pots and some other plants. Chemicals must, of course, be soluble and harmless, and at the same time potent to kill very low forms of life, as well as such things as eelworms, rotifers and woodlice, all of which are associated with glass-house sickness. G.

PROPAGATING ARAUCARIA EXCELSA.

THOUGH small plants of *Araucaria excelsa* are by some regarded as of too symmetrical a character, they are admired by many, and there is always a considerable demand for them. In order to keep up the supply, great numbers are raised from seeds, but the plants obtained in this way are not nearly as well furnished at the base as those raised from cuttings. As with all the regular growing conifers, it is, of course, useless to take cuttings of the side branches, as this branch-like style of growth will be always retained. In order to propagate these *Araucarias* from cuttings, the first thing to do is to obtain cuttings of the right sort. This is done by taking off the top of a plant, and if it is not too strong it may be utilised as a cutting. The old plant will after this often push up two or three leaders to take its place, and when these new shoots are from 4 inches to 6 inches in length, they form the best of cuttings. Put into small pots of sandy soil in a close propagating-case with a gentle heat, they will soon root and quickly form neat, well-furnished specimens. The old plants will continue to push up new leaders time after time. As illustrating the finely symmetrical plants that can be obtained from cuttings, attention may be called to a group of that new variety, Silver Star, which formed quite a feature at the Royal Horticultural Hall on June 3. H. P.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

SLUGS AND SWEET PEAS (J. F.).—The Sweet Pea foliage is being damaged by slugs, and probably the best remedy to apply will be soot or soot and lime, dusted on. Spraying the plants or watering them with an ounce of potassium permanganate dissolved in a gallon of water often proves a good remedy.

INJURY TO IRISES (G. K. M.).—The Irises are attacked by the bulb mite (*Rhizoglyphus echinopus*). This has destroyed parts of the bulbs and the roots, and the injury to the foliage follows as a result. It would be well to dig up all the bulbs as soon as the foliage dies off, and plunge them in water at about 110° for a short while. This will probably kill most of the mites without damage to the bulbs, and they may then be replanted in a fresh position.

LILY OF THE VALLEY (H. H.).—As you can do nothing to the bed before October, you might send us a sample of the weed which you say is choking the plants. It may be of a very insidious type, requiring the most drastic measures to get rid of it. You may discourage it by pulling up all that is possible, and encourage the

growth of the Lilies by frequent doses of liquid manure. In sending the weed, please direct our attention to this reply, when we will furnish full particulars as to what is best to be done.

MYOSOTIS (E. B. G.).—The plant is *Myosotis alpestris* Marie Raphael, and may be propagated from seeds and cuttings. The seedlings would, however, be sure to vary, and true stock could only be depended upon from cuttings. To obtain a stock by these means it would be necessary to plant a reserve batch apart, cutting them down as soon as the first flush of flowers was past. Then, by picking up the soil and giving a mulching of fresh material, new growth may be encouraged by watering and presently put to use as desired.

"FIRE" IN TULIPS (H. T. M.).—The Tulips are attacked by the disease called "fire," to which reference has been made frequently of late in our columns. We should think your soil must be affected by the fungus, which often passes the summer in the soil, and we would suggest that Tulips and other bulbous plants should not be planted in this bed for three or four years to come. There is no cure for the disease, but it would be well to remove all affected foliage as soon as possible, so as to prevent the disease from reaching the bulb and the fungus from forming the hard resting bodies called *Sclerotia* in the soil or in the bulb.

TREES AND SHRUBS.

CHANGE IN FORM AND COLOUR OF CLEMATIS (K. M.).—Are you absolutely certain no mistake has occurred with regard to the Clematis? The change of form and colour over a whole plant is extraordinary. Is it at all likely that the stock has grown up in place of the plant you had?

PLANTING CYTISUS (Andreanus).—If plants of *Cytisus andreaanus* prostratus are obtained in pots, they may be planted at once; but if they have to be lifted from a bed, the planting must be deferred until October. It is always better to obtain small rather than large plants, as they transplant more satisfactorily. Plants may be obtained from any of the leading nurserymen for 1s. or 1s. 6d. each.

GALLS ON AZALEA (H. S. N.).—The Azalea is attacked by the fungus *Exobasidium japonicum*. This fungus causes galls, which should be picked off and burned as soon as they are apparent. It is too late to avoid all danger of spread to the other parts of the plant now, as the galls have turned white, showing the spores are developed, ready to spread the disease, but the burning of them will minimise the danger.

GORSE SEEDLINGS (E. A. P.).—If you collect quite small plants of Gorse, not more than one year old, there is no reason why you should not establish them successfully in the autumn. At the same time, it would be advisable to procure seeds this year and keep them over the winter; then, if any of the plants die, a few seeds could be sown early next March with the object of replacing the dead plants. There is no reason why you should not collect sufficient seeds for this purpose; but if you wish to procure them elsewhere, any of the firms of nurserymen who make a speciality of forest trees and covert plants, such as Dicksons of Chester, Little and Ballantyne of Carlisle, or Wiseman and Sons of Elgin, would be able to supply them.

PRUNING SHRUBS (Dion).—It is not possible to treat all flowering shrubs in the way recommended for *Prunus triloba* after flowering. *Forsythia suspensa*, *Jasminum nudiflorum* and *Philadelphus Lemoinei* are other subjects that respond to the treatment recommended for *P. triloba*. A Lilac which is becoming leggy may be cut back after flowering; but it is not advisable to prune Lilacs back regularly. A great point in the successful culture of Lilacs is to restrict the growth of young shoots. The inside shoots and a number of the weaker outside ones should be removed when from 4 inches to 6 inches long, in order that all the energy of the plants may be devoted to perfecting the principal growths on which the best flowers are produced. If a mass of weak wood is allowed to grow, fewer and poorer flowers are obtained. Thorns may be shortened somewhat as soon as the flowers are over, and if the centres are full of weak branches, a few may be removed bodily in order to admit light and air to the remaining branches. It is not possible to give general instructions for pruning flowering trees and shrubs, as almost every kind requires slightly different treatment. As a rule, however, it is a good plan to do any necessary pruning after the flowers fade, and to keep the centres of the trees fairly open.

THE GREENHOUSE.

INJURY TO VINE LEAVES (Ernstii).—The damage to the Vine leaves has been brought about by keeping the Vines too close in a moist house with too high a temperature.

INJURY TO LILIES (L. W.).—So far as the specimens sent go, it would seem that the plants have been exposed to cold draughts. They may have been suffering from the "Lily disease" last year, but the symptoms of that trouble are not at all evident yet.

CARNATIONS AND GREEN FLY (M. O. J.).—It is quite possible that "the blight" referred to by you, which we take to be aphids or green fly, is on other plants as well as the Carnations, and, consequently, cleaning off a few of the insects will have no effect. By far the better plan will be to vapourise your greenhouse with one of the many meatine compounds now on the market, such as the XL All Vapouriser. If this is done two or three times at intervals of a few days, the pests will be entirely got rid of.

PALM LEAVES WITHERED (W. L.).—The two specimens sent are too meagre to enable us to name them with certainty. They look as though the conditions under which they are growing are not congenial, and the Palm certainly requires more heat than you can give it without fire in winter. It should have a dry temperature of about 60° at least in winter, and not below 45° to 50° at night. The Bamboos will probably put up with a lower temperature, but attention to the water supply is most important, and you will probably find the Bamboos are suffering more from this than from anything else.

PELARGONIUMS (R. H. B.).—Your Pelargoniums are attacked by a fungus which seems greatly on the increase throughout the country. Highly-fed plants, and those that have had an excess of water at the roots, or are kept in a close, stuffy atmosphere, are far more liable to be attacked than those grown under more natural conditions. With regard to this it must be borne in mind that in South Africa, the home of the Pelargonium family, a clear, dry atmosphere largely prevails. To combat the trouble, give the plants plenty of air, and spray occasionally with one of the many fungicides now obtainable. One very clean in its application is permanganate of potash, the crystals of which may be dissolved in water. The solution should, when ready, be of a pale rose colour.

PERPETUAL CARNATIONS (R. H. B.).—As your plants of Carnations are carrying six good shoots, they will not need to be stopped any more. For flowering, 6-inch pots would have been preferable to 5-inch; but if they do well, the strongest may be shifted into larger pots in July. When the roots take possession of the new soil, the plants will be much better stood out of doors than in a close and stuffy atmosphere, as a light, buoyant air is at all seasons very essential to the successful culture of these Carnations. When out of doors they must be stood on a well-drained place, and a gentle spraying with rain-water on the evenings of hot days will be beneficial. They must, by the end of August, be removed into the greenhouse, taking care that they have a good light position, with plenty of air, assigned them. In the winter the thermometer may range from 45° to 50° at night, rising 10° or 20° during the day.

ROSE GARDEN.

GREEN CORE IN ROSES (K. M.).—Certain Roses are very liable to the production of this green core, and we think it usually follows a check to growth, such as might be imposed by frost or a dry spell of weather just when growth should be active.

RAMBLER ROSES WITH BLIGHTED FOLIAGE (Peplered).—If you persevere with the Cyllin Soft Soap you will very soon check the green fly. When possible, dip the shoots in a bowl of the liquid for a few seconds. The bruised appearance of leaves is caused by cold winds, and possibly by slight frost. Perhaps the plants need a good sprinkling at the roots. Often rambler roses suffer more from drought than we generally suppose, especially if planted where the soil is not often hoed. Cover the soil with short manure, then give each tree three or four bucketsful of water, and repeat this twice a week.

MANURES FOR EXHIBITION BLOOMS (Rosary).—As you desire a change from liquid cow-manure, we should advise either Ichthemic Guano or Clay's Fertiliser, both of which are quick acting and excellent if given in moderation. An excellent quick-acting manure for Roses would be an ounce of nitrate of potash or an ounce of phosphate of potash in a gallon of water. Of course, if you give the latter you would not apply the former, and be careful to water the ground well previously if at all dry. In the case of the guano or Clay's Fertiliser, it would be well to water it in, so that the Roses obtain the benefit quickly. We should be inclined to favour the liquid manure as last recommended, and you could give the Roses the liquid cow-manure a week afterwards; then repeat the potash liquid a week after that, but withhold it if the Roses are showing colour.

ROSA SINICA ANEMONE WITH DAMAGED FLOWERS (H. E. B.).—We think the deformed petals are due as much to the season as anything. We have had the same occurrence on the earliest blooms, but the later ones are all right. Possibly the somewhat unripened condition of the wood is responsible for it. We cannot recommend any special treatment beyond the ordinary system of culture. As you know, Crimson Rambler produces its best clusters upon the wood of the previous year, so that you will do well to cut away as much of the old wood as can well be spared. In the case of *sinica anemone*, this should also have old wood removed to some extent after it has ceased to flower this season. The very small specimen you send us suggests that the plant needs attention in the matter of manure. It would be well to give it some good liquid manure to encourage a more vigorous growth during the summer.

MISCELLANEOUS.

PONDWEED AND COPPER SULPHATE (J. T.).—If you apply copper sulphate to the water in your ponds at the rate of one part of copper sulphate to one million parts of water, it is not likely to cause harm to cattle drinking the water, especially if a few hours are allowed to elapse before the water is used for drinking purposes. It has been amply demonstrated by American officials that copper sulphate applied at the above strength has no harmful effect upon human beings or animals, and fish live in water containing a much higher solution. You must estimate the cubical contents of your ponds, and reckon each cubic foot of water as weighing about sixty-two and one-third pounds. Be careful that the copper sulphate is distributed equally through the water.

SEAKALE ROOTS AFTER FORCING (A. E. H.).—Such forced roots are no good. Seakale is grown from root-cuttings planted in March, such cuttings making strong roots in the course of the summer and autumn following quite good enough to force in the following winter and spring. You should bear this in mind, and secure early cuttings in autumn or early winter. These should be planted deeply (in trenches) in soil where the position is cool until they are wanted in spring for planting in their summer quarters.

FUNGUS ON WILLOW AND ALLIUM (W. B.).—The Willow shoots sent for examination have been injured by the Willow canker fungus (*Melampsora alni-salicis* albæ). Two different stages of the fungus occur, one on Willow, and more frequently on rods grown for basket-making than on trees, and the other stage on *Allium ursinum*. If you watch the Willows carefully, you will doubtless find patches of bright yellow spores on the leaves and bark during summer, which result in the dead patches of which you complain. The only practical way to effect a remedy is to cut off the affected branches and burn them. If any wild *Allium* is growing in the vicinity, dig it up and burn it also. A description of this disease is given in "The Fungus Diseases of Plants," by G. Massee.

VARIOUS QUESTIONS (Ignatius).—The shrub sent for name is the Mexican Orange Flower (*Choisya ternata*). It may be increased by means of cuttings taken any time during summer, and inserted in sandy soil in a close frame or in pots in a greenhouse. It may also be propagated by layering the lower branches in spring. Throughout the milder parts of the British Isles it thrives quite well in the open ground, forming a large, shapely bush with little attention to pruning. In colder districts, however, it must be planted against a wall or be grown in a greenhouse. Any kind of fairly good garden soil suits it. It may be used as a tub plant for standing on terraces if it is so wished. The *Smilax* is a perennial plant, and is usually grown in a greenhouse or against the back wall of a vineery. It thrives well in a compost of two parts fibrous loam to one part of old Mushroom-bed manure or leaf-mould with a little sand. The best material for potting Geraniums is in three parts good loam to one part of old hot-bed or Mushroom-bed manure with a little sand. You can keep the foliage good by attending to the proper ventilation of the house and the proper watering of the plants. When the pots are well filled with roots, liquid manure should be given occasionally. It is probable that you have starved your plants in the past. Well-decayed manure is better than fresh manure for Potatoes. Either well-decayed farmyard manure or chemical manure rich in potash may be used. Do not manure too heavily, however, or the Potatoes will form too much haulm and too few tubers.

NAMES OF PLANTS.—Mrs. Cooke.—*Alonsoa inaeifolia*; *Begonia fuchsoides*.—*G. E. Bennett*.—*Pyrus Aria* (White Beam).—*G. B.*—Rose Flora.—*H. V. B.*—*Diervilla* (*Weigela*) *Eva Rathke*.

SOCIETIES.

NATIONAL HARDY PLANT SOCIETY'S OUTING.

ON Saturday afternoon, May 31, members and friends of the National Hardy Plant Society to the number of thirty-six travelled in a special saloon from Marylebone to Chorley Wood Station, whence, by the kindness of Adeline Duchess of Bedford, conveyances took the party to Woodside, Chenies, where they were received by Her Grace, who not only extended her visitors a cordial welcome, but devoted the afternoon to their entertainment, personally accompanying the party round the delightful and interesting gardens and afterwards presiding at tea. The gardens at Woodside are, by reason of their owner's wide knowledge and keen appreciation of hardy plants, full of charm and interest, and it need scarcely be remarked that the enthusiasts who constituted the party on Saturday spent a most delightful time inspecting the extensive herbaceous borders, the rockery (recently enlarged), and the sloping banks of the River Chess, which runs through the grounds, and which just now are bedecked with far-reaching masses of *Myosotis*, *Irises*, *Helianthemums*, and a host of other free-flowering plants of dwarf stature, and which thrive among rocky boulders let in the bank-sides. Large masses of *Primula japonica* in full flower were very fine, and in the herbaceous borders *Lupinus polyphyllus*, both blue and pink, and the fine rose-coloured flowers of *Agrostemma coronaria flore pleno* were prominent features. Free use is made at Woodside of *Hesperis matronalis*, and although now past, the faded flower-heads of great drifts of *Polyanthus* bore witness to what had been a glorious show. *Dianthus alpinus* on the rockery was just at its best, and many choice *Saxifragas* were flowering profusely. The hardy plantsmen were unanimous in their high appreciation of the serviceable collection of hardy plants so skilfully disposed and well grown, and Mr. John Dickson, the head-gardener, was the recipient of many congratulations. To go into details of the gardens and the extensive collection of plants would require a large amount of space, but for the present it must suffice to record the fact that the outing proved to be most enjoyable, well organised, and a happy combination of pleasurable recreation and profitable education to all who participated. Before the party left, the chairman of the society, Mr. E. Bouskill, in a few appropriate words, voiced the gratitude of all to Her Grace the Duchess of Bedford for her kindness in first permitting the visit to her gardens, and for so graciously honouring them with her presence as well as providing such hospitality.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

The Guelder Rose.—*Viburnum plicatum* is very attractive just now with its snowball-like heads of flowers. It is easy to manage and will thrive in any ordinary soil, which facts should make it more appreciated by suburban and town gardeners. If it is taken up and replanted every two or three years, a check will be put on any tendency to grossness, thus making it less possible to get unwieldy while at the same time increasing its flowering value.

Fruit Prospects for 1913.—According to the monthly report just published by the Board of Agriculture, the prospects for fruit during the present year are of a variable character. Strawberries, Raspberries and Currants promise to be good; but Gooseberries, though good in some districts, are bad in others. Pears, especially in the south-eastern districts, are below the average, while Apples promise a large crop. Plums and Cherries are about normal. In many instances that have come under our own observation, the last two fruits named failed badly in stoning.

A Glorious Garden Pink.—Few hardy plants that have been introduced during recent years have had such a warm reception as *Pink gloriosa*. This has all the good attributes of the old garden Pinks, and in addition gives us large, bold flowers of bright rose pink colour. Moreover, it remains in flower for several weeks, and in that respect is a great advance over old varieties. The flowers are as large as those of Mrs. Sinkins, but the calyces do not split as they do in that well-known variety, while, owing to its colour, it is far more effective in the garden. But its crowning glory is its scent, which has captivated every visitor to our garden during the last three weeks.

The French Honeysuckle.—Among the many plants that require to be sown now should be included *Hedysarum coronarium*, or the French Honeysuckle (a name that seems somewhat out of place, as the plant in question is neither a Honeysuckle nor a native of France). Its spikes of deep red flowers, often measuring from 4 inches to 6 inches on stalks from 2 feet to 3 feet high, are very effective at this time of the year. Its sweet scent has an attraction for the bees, so that it should be a useful plant to grow near their hives. There is a white form which is very seldom grown, and can hardly be considered equal to the type.

The Dwarf Mock Oranges.—Just now the several dwarf forms of *Philadelphus*, or *Syringas* as they are often erroneously called, are flowering freely, and their fragrant blossoms find a welcome in many schemes of house decoration. For small gardens they are ideal shrubs, because they give better results if judiciously cut back every year. As soon as flowering is over, a portion at least of the old wood ought to be cut away. Usually

strong young shoots will be found coming out from near the base, and if the old wood is cut down to these, much better results will be obtained next year. If left alone, these miniature Mock Oranges, generally referred to as Lemoine's hybrids, are apt to get rather thin and unsightly.

Scentless Musk.—At one time Musk was known by its fragrance, but for some unaccountable reason it appears now to have completely lost this precious gift. We have observed Musk in many gardens just lately, and while in some instances the owners have not been acquainted with the fact, yet in no case has any trace of fragrance been found. Now that Musk is flowering in widely-separated districts, it would be interesting to hear the experience of others. Sweet-scented Musk is in great demand, and there is a good future in store for anyone lucky enough to possess it.

An Interesting Experiment in Destroying Lawn Weeds.—Those who are in Southport during the next week or two should make a point of visiting Hesketh Park, where an interesting demonstration in destroying lawn weeds is being conducted. The Boundary Chemical Company offered to supply the authorities free with sufficient Climax Lawn Sand to dress the lawns in the flower gardens there. This offer has been accepted, and the lawn sand will be applied in two operations. It is not often that the public has an opportunity of seeing the results of a demonstration of this kind.

The Double White-Flowered Sweet Rocket.—How seldom one sees this fragrant subject doing really well in the gardens of to-day! The single form is widely grown, but the double variety is one of those plants that belong to the gardens of bygone days. We were reminded of the value of this plant (*Hesperis matronalis alba plena*) when visiting the gardens of J. C. Ems, Esq., Wood Hall, Dulwich. The fragrance in the eventide and the masses of double white flowers were a pleasure to remember. There is a secret in its cultivation, viz., to replant the side growths annually, otherwise the old clumps are inclined to rot off in the centre.

Cause of Silver-Leaf Disease.—This serious and puzzling disease appears to be more prevalent this year than ever. For several years past one school of scientists has favoured the idea that it was caused by one stage of the fungus *Stereum purpureum*, others being equally certain that there was no connection between the two diseases, and that the fungus only attacked the trees after they had been killed or seriously injured by silver-leaf. It is now rumoured that the latter theory is the more correct, as silver-leaf is said to have appeared among batches of first year seedlings, the seeds having been sown under conditions which rendered it unlikely that *Stereum mycelium* was present in the soil. Whatever the source of the disease, it is a most serious one and we trust that definite information as to its origin and cure may soon be forthcoming.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Primula Leddy Pilrig.—I find that I must have made a mistake in my letter to you about *Primula Leddy Pilrig*, which you reproduced in *THE GARDEN* for June 7, page 286. My gardener tells me that *P. beesiana* is the pollen parent and has perfume, *P. bulleyana* being the seed parent. It (*P. bulleyana*) is scentless. I am sorry to have made the mistake, as I said *P. bulleyana* was responsible for the perfume and was the pollen parent.—B. BALFOUR-MELVILLE

Lithospermum prostratum at Comlongan, Dumfriesshire.—The lovely Prostrate Gromwell is cultivated with remarkable success in the beautiful garden of Mr. A. H. Johnstone-Douglas at Comlongan Castle, Dumfriesshire, both on rockwork edging in the flower garden and in the rock garden. Big clumps in the most perfect condition are to be seen, and one mass, only four or five years old, measured

Apart from the flowers, the foliage is just about the same.—H. P.

The Germination of Peas and Beans.—For some reason or other several of the Marrowfat varieties of Peas and the tall and dwarf Runner Beans have not germinated very satisfactorily this season. Scarlet Runners have come very irregular, and the Dwarf French Beans came so poor as to make resowing necessary, a task I have not had to do for some years. A gardener at an institute told me the other day that out of five or six quarts of Peas he had not obtained one really good row. The round Pea—Pilot, for instance—has, with the writer, come well, but the Marrowfats are more sparse and weakly than usual. It would be interesting to hear if the above experience is shared by others or peculiar to this locality.—C. T., Highgate [We have found both types of Peas germinate well, but Beans very poorly.—ED.]

The Sun Roses.—The various kinds of Helianthemum are not planted half so freely as they ought to be, for they thrive under conditions which would be almost impossible for many other

to have any effect on them. Excellent they may be in a garden, not in an apiary.—K. T. [We sent a copy of this letter to an expert bee-keeper, and publish herewith his reply: "The letter *re* toads and bees brings forward an interesting point. Both are so useful in a garden that it seems a pity they cannot live together amicably. I have only once before heard of a case where a toad did any appreciable harm to a colony of bees. If the apiary is kept free from all vegetation for some distance round the hives, and the ground strewn with fine cinders, I do not think the bees would be much molested. The alighting board of each hive should be kept free of the ground, and a little slaked lime might be sprinkled on the ground around the hives. The bees that fall victims to the toad are probably the old, worn-out ones. The hives should be so arranged that it is impossible for a toad to climb up on to the alighting boards. It would be a great pity to destroy toads in a garden. I import numbers into mine, and I do not think I have ever lost a bee from that cause."—ED.]

SOVEREIGNTY.

The Snowdrop came like infancy,
Whose coming ever must assure
A dubious world that life may be
Divinely fresh and pure.

The Crocus awakened, as a child
Awakes to marvel at the day
And win the winds, that seem so wild,
To light and genial play.

A romping girl, the Daffodil
Wore a mock dignity—soon lost
When, grown forgetful to be still,
Her golden head she tossed.

The Violet was a gentle maid [light,
Who, having seen heaven's dazzling
Would turn aside, as though afraid
To trust her questioning sight.

The Lily passed, a virgin fair,
So stately and so passionless,
It seemed that ev'n the very air
Might venture no caress.

The Rose? Ah, welcome, sovereign
Rose!
As womanhood serene, complete,
That all heaven's influences compose
To beauty nobly sweet.

JAMES CARTWRIGHT.

A BEAUTIFUL COLONY OF SUN ROSES. THESE THRIVE WELL IN POOR, DRY SOIL.

quite 6 feet in length by over 2 feet across on an average. This was on a rockwork edging. In the rock garden it is also very fine, though none of the clumps had as yet attained the dimensions of that mentioned now.—S. ARNOTT.

Pæony L'Espérance.—This Tree Pæony, which was figured in *THE GARDEN* for June 14, is, as far as I know, the first hybrid obtained from the yellow-flowered *Pæonia lutea*, whose introduction some years ago aroused a deal of interest. It was raised by M. Lemoine of Nancy, who has also given us the double-flowered *Gloire de Lorraine*. Whereas this last named was, however, only distributed in 1912, the variety *L'Espérance* was sent out in the autumn of 1909, its price of twenty-five francs being very different from the eight guineas of *La Lorraine*. As stated in your description, the general appearance of the two would suggest that they have one common origin, the main distinctive feature being that the flowers of *L'Espérance* are only semi-double, whereas those of *La Lorraine* have the duplex character very pronounced.

plants to succeed under, and always bloom freely. Quite recently a magnificent lot of plants were noted growing upon the summit and sides of a stone and earth wall. They were the picture of health, and the glowing masses of white, yellow, pink, red and purple blossoms presented a very attractive picture. Providing the precaution is taken of planting quite small plants from pots, there is no difficulty in getting them to establish themselves either on a wall or on a dry bank; but large plants cannot be transplanted well. It is also a wise plan to destroy old plants which show signs of deterioration and begin again with young stock, rather than try to rejuvenate the old ones.—D.

Toads in the Garden.—In the issue of *THE GARDEN* of the 7th inst. a correspondent writes that he accidentally killed two toads with an insecticide powder. Could your correspondent give me the name of the powder? I should be much obliged, as I have been greatly troubled with toads round the bee-hives eating my bees, and nothing seems

A Useful Greenhouse Plant.—The striking feature that *Jacobinia magnifica carnea* presents when displayed in a mass or clump is well illustrated in the greenhouse at Kew, where there is a large, semi-circular group in full flower. It is an old plant in gardens, but is by no means so generally met with as its merits entitle it to be. Like many other acanthaceous plants, it must not be continually stopped in order to obtain a bushy specimen, as stout, vigorous growth is necessary for the production of those large, massive heads of rosy blossoms upon which so much of the beauty of the plant depends. Its propagation and cultural requirements are not at all exacting, as cuttings strike root readily, and the growing plants will thrive in ordinary potting compost. During the growing season these *Jacobinias* require a temperature above that of an ordinary greenhouse, but at the same time the plants must not be kept too close and warm, otherwise they will run up tall and weak. In some gardens the *Jacobinias* are included in the genus *Justicia*.—H. P.

Snake's-head Fritillary and Forget-me-nots. It may interest readers to know that I have this spring obtained very pretty effects in the wild garden with Forget-me-nots and *Fritillaria Meleagris alba*. Large masses of these flowers growing wild in the grass produce an effect both uncommon and beautiful.—L. B. W., *Somerset*.

Shrubby Pentstemons.—The award of merit recently given to Pentstemon Davidsoni will likely stimulate interest in the other shrubby Pentstemons, of which *P. Menziesii* (Scouler) may be taken as the type, and which have such a jumble of names and synonyms as to be difficult to unravel. I have grown *P. Menziesii* here for about eight years, and have had fair success with it. This year is, however, a poor one with me; but in the garden of Mr. Robinson-Douglas of Orchardton, in the Stewartry of Kirkcubright, I was delighted to see a fine plant of a good variety of *P. Menziesii* with charming light purple flowers in great plenty. It does one good to see such a fine plant, as, apart from the pleasure derived at the time, it whets one's desire to grow it even better than before—a feeling worth encouraging with such flowers as this. It is in a sunny position in the rock garden at Orchardton, and less exposed to wind than my own plant, which is also in a sunny place. At Orchardton it is planted among the stones, and is in sandy peat. It is an excellent specimen, and has been there for quite a number of years.—S. ARNOTT, *Dumfriesshire*.

The Forget-me-not in the Pleasure Ground.—The note under this head, on page 273 of your issue for May 31, appeared on the eve of my writing to draw attention to the use of this pretty little blue flower in combination with others, for it is not only on the grand scale that things are carried out at Kew that the modest little flower can be made effective, but even on a small bit of rockery bounding some garden steps, at the rear of my house, some very pleasing combinations have occurred by the accidental mixture of the common Forget-me-not and the wild Woodruff (*Asperula odorata*), which I introduced from a neighbouring hedge bank a year or two ago; and even another pretty effect has been produced by the Woodruff encircling a young plant of the common Bracken, the fresh green fronds of which, springing from the centre of a mass of the white flowers, forms a natural, though somewhat gigantic bouquet, which scents the air around it. The drawback against the Woodruff is, of course, the difficulty in keeping it within bounds when once it has taken possession of the ground.—JOHN R. JACKSON, *Claremont, Lympstone, Devon*.

—The reference to *Myosotis alpestris*, as grown in the pleasure grounds at Kew, in "Notes of the Week," issue May 31, should induce many amateur cultivators to treat this lovely plant more hardily than they generally do. I have found that in some soils (in town gardens especially) the well-cared-for young plants rot badly in the winter, the centre of each clump decaying. Self-sown seeds in a hard surface give resultant plants which withstand the winter splendidly. Seeds should, therefore, be sown in firm ground.

FORTHCOMING EVENTS.

June 25.—Norfolk and Norwich Rose Show (two days). Southampton Royal Horticultural Society's Rose and Sweet Pea Show. Flower Shows at Croydon, Harrow and Richmond.

June 26.—Canterbury Rose Show.

June 28.—Windsor Rose Show. Reigate Rose and Sweet Pea Show.

TREES AND SHRUBS.

SOME USEFUL SHRUBS FOR THE WILD GARDEN.

THE BUSH HONEYSUCKLES.

DURING the months of January and February a good deal is heard about two species of bush Honeysuckles, *Lonicera fragrantissima* and *L. Standishii*, but later in the year little or no notice is taken of the many other species belonging to the same group, although when seen at their best a number of them are very beautiful. The bush Honeysuckles, as a rule, are not very popular, probably by reason of their requirements being imperfectly understood, for it is freely admitted that they sometimes blossom very indifferently. The reason for this, however, appears to be that too much attention is given to pruning, for bushes which are pruned each year rarely blossom well, whereas quite good results are obtained from those which are allowed to develop freely and are practically left unpruned. To allow of this method of cultivation being carried out, though, abundance of room must be allowed, for some of the species form very large plants, anything between 8 feet to 15 feet in height and 10 feet to 15 feet in diameter. As a rule, good loamy soil is the most satisfactory rooting medium, and propagation is easily effected by cuttings or seeds.

The Best Position and Soil.—Many of the species form shapely isolated specimens, especially if given a position exposed to full sun. If planted in shrubberies, they must be so placed that they will not overgrow less vigorous plants, and for this reason they are better suited for the wild garden where each plant can grow alone, or a number of plants of one species can be grouped together.

Lonicera tatarica is one of the commonest species. A native of Siberia, it grows into a large bush at least 10 feet high, and bears its flowers in pairs from the leaf-axils of the young growths during late May and early June. The flowers are fragrant and white suffused with pink. The varieties *pulcherrima*, *punica* and *speciosa*, however, have reddish or pink flowers. Quite different from this species is the North-West American *L. involucrata*. Forming a bush 8 feet or 10 feet high and as much in diameter, it has dark green, oblong leaves and showy flowers. As is the case with all the bush kinds, the flowers appear in pairs from the leaf-axils of the young shoots. In this case each pair of blossoms terminates a slender stalk about two inches long, and about their base are two large dark red bracts, which continue after the fall of the flowers and form a protecting covering for the shiny black fruits. The flowers are tubular, reddish brown on the outside and orange within. *L. hispida* is a charming species from Central Asia and Siberia. As its name implies, it is very hairy, the young shoots and leaves being densely covered with soft hairs. The leaves are broadly ovate with a cordate base, the upper surface being green, the under surface glaucous. The fragrant, pale yellow flowers are produced from a few of the leaf-axils about the base of the current year's wood, and each pair is enclosed by two large green bracts which form a cup-like receptacle. The flowers are upwards of an inch in length and about three-quarters of an inch across the mouth. A very dainty plant is found in *L. syringantha*, a native of China. Growing to a height of 5 feet or more, it is made up of many slender branchlets, clothed with tiny oval leaves

which scarcely attain three-quarters of an inch in length, and bearing during late May and early June pretty pale lilac, fragrant flowers. Another showy kind is found in *L. pyrenaica*. This native of the Pyrenees is of less vigorous growth than many of the other kinds. Forming a bush 2½ feet to 3 feet high, it is conspicuous by reason of its rather large white, pink-flushed flowers, and at a later date by its bright red fruits. *L. microphylla* is after the style of *L. syringantha*, but the flowers are smaller. It, however, has a similar elegant habit and is a useful shrub. The Chinese and Maudshurian *L. Maackii* has created some considerable attention during the last few years, owing to Messrs. Veitch having exhibited well-flowered bushes on several occasions among their new Chinese plants. It is a vigorous-growing plant, attaining a height of 10 feet or 12 feet, and producing its fragrant, white flowers with considerable freedom. *L. Ferdinandii*, a strong-growing, wide-spreading plant, is peculiar by reason of large ear-shaped stipules which clasp the stem about each pair of leaves. The yellow flowers appear from the leaf-axils, but are continued to the points of the shoots, thus forming terminal inflorescences. In many other cases the flowers are restricted to the base or centre of the shoots. *L. translucens* is a large, dense-growing bush with cream-coloured flowers. Its fruits are whitish when ripe, and they are so transparent that the black seeds are easily seen through their pulpy covering.

Quite different in colour from the rest of the species are the flowers of *L. Maximowiczii*, a tall-growing plant from Amurland. In this case the flowers are purple. *L. deflexicalyx* is another large-growing, spreading species, which bears yellow flowers with considerable freedom. It forms a good specimen plant, but must have abundance of room. *L. rupicola* is distinct from other kinds, for although its long, slender branches have a somewhat scandent habit, it grows into a shapely bush 5 feet to 6 feet high. The leaves are about an inch long, ovate and dark green, and the flowers are lilac in colour. A semi-evergreen species is noticed in the Chinese *L. pilcata*. This spreads rapidly, but does not increase very fast in height; therefore plants may be 3 feet or 4 feet across, but not more than 1½ feet high. The flowers are greenish white and fragrant. *L. nitida* is a charming little plant of compact habit, with tiny oval leaves of an evergreen character. *L. nigra* and *L. xylosteum*, on the other hand, are large, vigorous plants up to 15 feet high and as far across. Both bear whitish, fragrant flowers.

The two winter-flowering species already referred to should, of course, be grown, for any shrubs which blossom during midwinter are valuable. Then there are many other kinds of greater or less merit available, but for most gardens a selection of the foregoing species will be found sufficient to include among other shrubs. D.

PROPAGATING WEIGELAS.

THESE useful flowering shrubs, now classed by the Kew authorities as *Diervillas*, may be easily propagated during the next few weeks by means of cuttings. These should be made from the partly-ripened side shoots, which are best slipped off with a heel of the older wood attached. If this is smoothed over with a sharp knife and the cuttings planted in well-drained pots of sandy soil, and these subsequently plunged in Cocoanut fibre refuse and covered with bell-glasses, roots will quickly form. When well rooted, the young plants must be given an abundance of air and light. H.

THE ROSE GARDEN.

THE BEST ROSES FOR HOUSE DECORATION.

ALTHOUGH undoubtedly there are some Roses better than others for lasting well when cut, it is a well-known fact that the quality of the blooms and the time at which they are cut are great factors in promoting good lasting conditions. A Rose devoid of substance and weak in stem will rarely appear well in the house, whereas the same variety from a well-

DO ROSES DETERIORATE?

Yes; to a certain extent I think a few of them do, and I will endeavour to point out a cause of this later on. But undoubtedly the chief impression of deterioration arises—paradoxical as it may seem—from the wonderful improvements among them during the past two or three decades. Most of us who have closely watched the behaviour of varieties propagated in a reckless manner—by which I mean minus any care or thought in selection—will agree that that variety will surely deteriorate. We find similar results in all phases of existence, no matter what position in the world they may hold.

Scotch Briars. But is not this to be attributed to position and culture? Formerly they, with a few Bourbons and Damasks, formed the chief Rose display in our gardens, and so were naturally accorded more favourable situations and culture than is the general rule now. It is not that they have deteriorated so much as the fact of their relegation to some odd corner, with the natural consequence of less care and attention.

One more thought. Do we not often find a new Rose come disappointingly inferior to those blooms exhibited by the raiser? In the first place, he had the advantage of a large stock to choose from, and, of course, showed his best. But a great deal of this inferiority arises from the use of every little fraction of growth in the desire to increase stock for sale, all but the owner of the stock plants having little choice of selection, and using good, bad and indifferent wood to get as many plants as possible while the price is high. I feel certain that not a few of our new Roses are injured, as a family, by the excessive propagation of all growth, even to the extent of increase from plants that are already a mere travesty upon the original. A. P.

A GOOD NEW ROSE.

The accompanying illustration represents a typical bloom of the new Hybrid Tea Rose Mrs. C. Reed, said to be a sport from the well-known Frau Karl Druschki. When shown at the National Rose Society's exhibition in London last year, this newcomer received a silver-gilt medal, an award that, we think, was fully justified. The flowers are of silvery pink colour, very erect and, what is most valuable of all, deliciously fragrant. The growth is robust, somewhat after the style of Baroness Rothschild, and the plants flower wonderfully freely over a long period. We understand that it will not be sent out before next year, but it is a Rose to note for inclusion with older sorts when it is obtainable. We are indebted to Mr. Elisha J. Hicks of Twyford, Berks, for the photograph reproduced herewith. Mr. Hicks exhibited a number of flowers of this Rose at the Royal Horticultural Society's meeting on the 3rd inst., when their fragrance was freely commented upon.

ROSE MRS. C. REED, A NEW SILVERY PINK HYBRID TEA THAT IS VERY FRAGRANT.

cultivated plant may last a week. Rose blooms should never be cut in the heat of the day. Early morning or late evening is best, and they should be placed in deep jars of water immediately they are severed from the plant. If the foliage could be immersed, so much the better, and I prefer to keep the blooms for a few hours in a dark cupboard in a cool shed or cellar before placing them in the house.

Roses should never be cut full-blown. Exhibitors know this only too well. A Rose will grow in water, so that if cut at the most in the half-open stage it is best. A few good "stayers" are Frau Karl Druschki, Mrs. John Laing, Ulrich Brunner, Mme. Abel Chatenay, Prince de Bulgarie, Sunburst, Souvenir de Gustave Prat, Liberty, Antoine Rivoire, Joseph Hill, Pharisäer, Hugh Dickson, Countess of Derby, Walter Speed, Gloire Lyonnaise, Jean Noté, Joseph Lowe, Mrs. George Sawyer, Lady Ashtown, Laurent Carle, Melanie Soupert, Mme. Ravary, Mme. S. gond Weber, Margaret, Melody, Mrs. Aaron Ward, Mrs. David McKee, White Maman Cochet, Mme. Hoste, Lady Roberts, Paula, Molly Sharman Crawford and Mrs. Foley Hobbs. There are many others, but this is a good representative list. DANECROFT.

But this does not wholly account for the evident deterioration of that old favourite yellow climber Maréchal Niel. Here we seem to have gradually lost the charming and healthy vigour so characteristic of it thirty and more years ago. It is much the same with Souvenir d'Elise Vardon and Souvenir d'un Ami. I do not find the beauty and size in these now, and this cannot be all fancy when one refers to the dimensions recorded of previous flowers, because our measurements have not decreased in any way.

Far too often when propagating, one is somewhat loth to make use of the most superb growth upon the plant, and this, I feel certain, works steadily towards deterioration rather than not. It is not alone the enthusiastic amateur who fails in this way—most trade growers are chary in taking the best from their stock; and even when plants are set on one side solely for propagation, the constant hacking away of the fittest wood must tend towards a more or less weakened constitution, and thus we come to the conclusion that the variety has deteriorated.

I am induced to give these few notes from a remark of a friend the other day, who expressed deep regret at the falling off of our Mosses and

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Brussels Sprouts.—It is high time that an extensive quarter of this indispensable autumn and winter vegetable was planted, and those who have not yet made a start must put the work in hand forthwith. That deep, friable, fertile soil is essential to success none will dispute, but there is little doubt that some amateurs and cottagers use more natural manure than is really necessary. However, this is a detail of management which must be governed by the individual merits of a case, and must, therefore, be left to the discretion of the grower. The distance between the rows and the plants in them will vary with the habit of the variety grown, the old-fashioned, big ones demanding 3 feet in all directions, whereas more compact-growing modern varieties will be adequately accommodated when the rows are 30 inches asunder and the plants are allowed 24 inches in them. The soil of the seed-bed should be thoroughly watered the evening before planting if the weather is dry, and similar treatment may be meted out to the permanent quarters, though

in this case it is often only possible to soak the particular positions that will be occupied by the plants. It is wise to plant firmly, and to water in directly afterwards.

Late Peas.—We must have Green Peas in the garden until the latest possible date, and every year there is something problematical in the results which will be achieved from sowings made between the present date and the middle of July. It is, in my opinion, always worth while to sow a variety such as Sutton's Early Giant during the last week of this month. The seeds germinate quickly in the warm soil, provided, of course, that it contains enough moisture, the plants grow rapidly, and in a favourable season will give a most welcome crop of late Peas which will equal in flavour any of their predecessors. When July sowings are made, it is usually of a hard-seeded variety, and the quality then drops considerably. The soil must be deeply cultivated, in excellent heart and firm.

Asparagus.—With the present date the cutting of Asparagus ought not to be as hard as it has previously been, and certainly the grower must be perfectly sure that enough "grass" is retained to build up strength in the crowns, or the results next season will be the reverse of satisfactory. Some cultivators have a rule never to cut the first and second growths that push through the soil, and it is an excellent system to adopt, but demands more self-control than many of us possess. See that no weeds are permitted to grow, or it will be most difficult, perhaps impossible, to thoroughly cleanse the bed before the tops are cut off in the late autumn. With the advent of July all cutting must cease if future results are to be really good.

Celery.—The planting of Celery should be proceeded with apace, and the importance of closely observing a few details cannot be over-estimated. For example, suckers spring from the root-stock, which, if permitted to remain, will ruin the plants; while if the leaf-miner works unchecked, debilitation will be so severe that the plants can never be excellent. The remedy for the former trouble is obvious—the suckers are cut off; against the leaf-miner dust the plants frequently when they are damp with a mixture of old soot and wood-ashes, and there will be little about which to worry. Then, too, the roots must go into fresh soil, and not in the possibly sour under soil that is exposed in forming the trenches. When the manure has been dug in, add a layer of 3 inches or more of excellent soil to accommodate the roots, and see that they never suffer from the want of water.

Outdoor Tomatoes.—In favoured gardens the Tomatoes for fruiting out of doors would be planted at the beginning of the month, but in cold gardens where the soil is heavy the present time will be wisely chosen. The earliest plants should be splendidly established, and will demand regular attention in removing the axillary shoots to concentrate all the energy in the one stem. If the first fruits are malformed, as so commonly occurs on healthy, vigorous plants, let them be removed without delay.

ROCK AND WATER GARDEN.

A ROCK GARDEN FIVE MONTHS AFTER CONSTRUCTION.

ONLY those who have actually carried out the work of constructing a rock garden, or have watched the work from the commencement, know how quickly it can, with judicious care, be clothed with growing vegetation and made to appear as though it had been *in situ* for many years. On a genial day towards the end of April we availed ourselves of a long-standing invitation to see Mr. W. A. Binney's garden at Weybridge, and although it is not a large one in the strict sense of the word, we found it packed with interesting features from end to end. The main reason for this is, undoubtedly, that Mr. Binney does the greater part of his gardening himself. As he is a member of the Council of the Royal Horticultural Society, we naturally expected to find it well done, and in this we were not disappointed. But it was the charming little rock garden that interested us most. Constructed barely five months previously by Messrs. Pulham and Son, and planted entirely with Mr. Binney's own hands, it was a splendid

better, for large masses of it were tumbling about in riotous profusion, and each and all were gaily clothed with the bright red, erect flowers. Large plants of Sun Roses, or Helianthemums, were full of buds, and gave promise of a gorgeous display later; while such gems as Iris pumila, Arenaria balearica and A. montana, Asia Minor Tulips, Veronica repens, Polemonium confertum melitum, Cheiranthus Alboni, Corydalis nobilis, Pentstemon Scouleri, Phlox setacea G. F. Wilson, Viola gracilis, dozens of encrusted Saxifrages and many other plants abounded on every hand. We think for a rock garden of its size it would be difficult to beat this example, both in construction and planting.

THE VARIEGATED GARLAND FLOWER.

(DAPHNE CNEORUM VARIEGATUM.)

ALTHOUGH not a great advocate of the cultivation of plants with variegated leaves, one must say a word or two in favour of *Daphne Cneorum variegatum*. It is well known that the ordinary Garland Flower is a troublesome plant with many, and that it is frequently lost in a number of gardens. It is asserted, and, so far as my experience goes, with truth, that the variegated form is hardier, or, at least, more easily cultivated for many years than the green-leaved one. If this is the case—

A ROCK GARDEN FIVE MONTHS AFTER IT WAS CONSTRUCTED.

example of what loving care and enthusiasm can do in so short a time; and with a view to encouraging others to go and do likewise we publish an illustration of part of it herewith. Unfortunately, rock gardens do not lend themselves well to photography, and the best of illustrations only convey a rough idea of the general outline of construction and the main features.

But this rock garden is really well stocked with more or less choice plants, the majority of which appeared quite at home and might have been planted for years. We have never seen that glorious red Saxifrage, *Saxifraga bathoniensis*, doing

and the evidence on this point seems pretty conclusive—the variegated variety deserves some attention from those fond of these charming *Daphnes*. The variegation is not at all obtrusive, and is, though present, not noticeable without a closer inspection of the plant than is necessary. The growth and habit are the same as those of the ordinary Garland Flower, but it is a free and happy grower even in places where *D. Cneorum* itself dies off. I have here a good plant which has been in this garden for seven or eight years, and Mr. W. J. Maxwell, Terregles Banks, Dumfries, has a beautiful specimen in full health on his rock garden.

In May and June this Garland Flower is a picture, with its charming pink or rosy lilac flowers. A peaty, gritty soil is the best for it

Dumfries.

S. ARNOLD.

SOME INTERESTING AQUATICS.

The Water Hawthorn (*Aponogeton distachyon*).—This delightful small-growing aquatic has been flowering for some time, and is one of the very best subjects that could be included for any position in shallow water and where the stream is not too fast. It continues to flower more or less from now onwards through the summer and autumn, and is perfectly hardy. The white flowers, splashed with black anthers, float on the surface, and are greatly admired. Especially is this so when the plant can be situated close to an overlooking bridge. The blooms have a

not far away from the edge of the banks. Unless suitable pockets are made, as is often the case with artificially-constructed streams, the plants should be sunk and fastened down to the mud, into which they will soon establish themselves, by which time their temporary receptacle, such as a wicker basket or punnet, will have rotted away.

***Pontaderia cordata*.**—The present month is one of the best times for planting most water-loving subjects, and it is not too late for this summer-blooming plant. A colony near to the bank, when established, forms an imposing sight. *Pontaderia cordata* is commonly known as the Water Plantain of Jamaica. It produces large, handsome foliage, which stands out of the water together with the spikes of deep blue flowers, which are freely produced. *P. cordata* is unique by reason of its colour, and is, therefore, one of those subjects we cannot afford to be without.

PRIMULA INVOLUCRATA IN A SCOTTISH ROCK GARDEN.

I HAVE long known and admired the charming *Primula involucrata*, and have seen it now in a goodly number of gardens, and always with a growing appreciation of its beauty, yet it was only a few days ago that I ever realised its absolute charm, and this was through seeing it in the rock garden of Mr. W. J. Maxwell at Terregles Banks, Dumfries, where, in addition to other plants, there is a nice group of *P. involucrata* in a hollow formed by rockwork capped by Mossy Saxifrages and other alpines. Looking across at this clump of *P. involucrata*, one saw it with a background of one of the larger white Mossy Saxifrages, and could then realise the purity of the colour of the flowers of the *Primula*. One would hardly expect a white Mossy Saxifrage to form a good background for *P. involucrata*, but it did, and the effect was indescribably beautiful. It was a harmony, yet a contrast. The *Primula* was very beautiful, the stout stems carrying a number of perfect flowers of purest white, redeemed from absolute coldness by the yellow eye. In Mr. Maxwell's garden the drainage is absolutely perfect, and even such a moisture-loving *Primula* as this appreciates the free run for surplus water.

S. A.

THE CREEPING SANDWORT (*ARENARIA BALEARICA*) IN THE ROCK GARDEN.

delicious fragrance, resembling Hawthorn, though not so overpowering. *Aponogeton distachyon* is also a splendid subject for a small pool or basin in any house or conservatory where a greenhouse temperature not too warm is maintained.

Golden Club (*Orontium aquaticum*).—This is another aquatic that lovers of water gardening should not fail to be without. Like the foregoing, when once established there is no difficulty experienced with it; but if taken care of, innumerable seedlings will in time be found round the parent plant. Besides being particularly attractive when in bloom, with its broad, glaucous foliage resting on the water and surmounted with its spikes of rich golden yellow, another valuable characteristic is that it commences to bloom considerably in advance of any of the Water Lilies and remains fresh for a long time. *Orontium aquaticum* is a native of North America, and succeeds best when planted in fairly shallow water

It will quickly establish itself near to the bank so long as the roots are submerged.

Aldenham House.

EDWIN BECKETT.

THE CREEPING SANDWORT.

(*ARENARIA BALEARICA*.)

This is an indispensable Sandwort for clothing bare rocks and stones on the shady side of the rock garden. It clings closely to the rocks, forming a carpet of green, which, in early summer, is smothered with dainty white flowers. So long as this Sandwort is not exposed to the full sun it will clothe the largest rocks with its clinging foliage. It needs only a glance at the accompanying illustration to get an idea of its mode of growth and freedom of flowering. It is quite a good subject for clothing the rocks in association with hardy Ferns or other shade-loving plants. It is a native of Corsica and was introduced as far back as 1787.

COLOURED PLATE.

PLATE 1473.

A NEW DWARF YELLOW ARUM LILY.

(*RICHARDIA* MRS. ROOSEVELT.)

At one time the only Arum Lily at all extensively grown was *Richardia africana*, otherwise known as the Lily of the Nile or white Arum, a very elegant and still a deservedly popular plant. The yellow Arums are of later introduction; the two species *R. eliottiana* and *R. Pentlandii*, the latter with a deep purple-brown blotch at the base of the spathe, each created a mild sensation when shown for the first time. In the variety Mrs. Roosevelt we have the most recent introduction,

and it is claimed to be the only yellow Arum suitable as a garden plant. The light yellow flowers and beautifully-spotted foliage make it an object of interest and beauty. It is a plant that cannot fail to arrest attention, and when seen in a group it creates a remarkably fine effect. It is quite free-flowering, and does well in almost any garden, more especially where the soil is rich and supplied with plenty of moisture. The growers of hardy flowers have the highest opinion of this plant. Not only is it easily grown, but it continues to flower for eight or ten weeks during the summer months. The following cultural notes will, it is hoped, prove helpful to those who contemplate the inclusion of this novelty in their gardens. The tubers are perfectly hardy, and should be planted in a moist situation, liberal supplies of water being necessary throughout the growing season. When dormant, the tubers should be covered with about two inches of soil, to which

The New Yellow Arum Lily
Mrs. T. H. Roosevelt.

decayed manure should be added from time to time as growth advances. By following out this plan the roots are kept both warm and moist, and provide just the conditions for growth that are necessary in the spring of the year.

This new *Arum*, as its name implies, originated in America, and when shown at St. Louis received a gold medal. Since then the Dutch Bulb Growers' Association have granted it a first-class certificate. A number of nurserymen in this country, and also on the Continent, now hold good stocks of it, for which, when its merits become better known, we think there will be a large demand. Unfortunately, owing to the large size of the foliage, the coloured plate does not show the characteristic gracefulness of the plant, which needs to be seen growing to appreciate its beauty to the full.

FLOWER GARDEN.

EREMURI IN THE WILD GARDEN.

THE larger of the *Eremuri* are fine plants for the outskirts of the garden, or preferably for well-sheltered, sunny places in thin woodland where this adjoins the garden. Their whole aspect is so surprising and the height of the giant flower-stem so great that they are out of scale with ordinary garden plants; moreover, the one that is most generally grown, *E. robustus*, has large roots that radiate horizontally, much like a cart-wheel without the tyre, so that each plant requires an uninvaded root space of 5 feet diameter. Although so large, the roots are of a brittle texture, easily broken; they are impatient of any disturbance and need careful handling at planting-time. This should be when the plants are not more than three years old. They enjoy deep, sandy loam, well drained and well enriched, and are thankful for a protective winter mulch. The grouping as shown in the picture is a little scattered; it is best, whenever possible, so to place them that the group tells more or less as one mass from the spectator's point of view. In the case of plants such as these, whose nature of root prevents their being planted near together, the effect of good grouping can be obtained by having the length of the group running front and back, or, better still, diagonally to the path from the chief point of sight, rather than at intervals along both sides of the path.

E. robustus rises to a height of 10 feet. There are others of the genus that can also be grown anywhere to the South of London. For garden grouping and good colour arrangement they fall into two groups, viz. *E. robustus*, flowers pale pink; *E. himalaicus*, with a beautiful white

flower, 7 feet to 8 feet; and *E. Olga*, pink, about three feet high. The plants of the other group have flowers of yellow or yellowish colour and are of lower stature. The most useful of these are *E. aurantiacus*, from Afghanistan; *E. Bungei*, a Persian plant, rather tender; and the quite hardy *E. spectabilis*. None of these exceed a height of 3 feet.

The strap-shaped foliage of the *Eremuri* is all radical, and does not in itself make much effect. It is well to group near them plants with leafage of a different class and of bold effect, and with flowers whose colour will neither clash with nor overpower the tender colouring of the giant spikes.

AN EFFECTIVE GROUPING OF EREMURI IN THE WOODLAND OR WILD GARDEN.

Such would be the great *Heracleums*, of which *H. mantegazzianum* is much the best, and the ornamental *Rhubarbs*. These should be at the back, and, more forward, such plants as the larger of the hardy Ferns, *Rodgersia podophylla*, with its handsome red bronze leaves of Horse Chestnut shape, and the bold form and tender pink bloom of *Saxifraga peltata*, with a background of all of trees of dark foliage.

G. JEKYLL.

SOME USEFUL HARDY PLANTS.

Many species of the genus *Orobis* should be represented in those gardens where herbaceous plants are treasured. They are classed by some as

a division of *Lathyrus*, which they closely resemble, differing, however, in having no tendril at the tip of the petiole. Their culture is easy; any good soil and a fairly sunny position fulfil their requirements. They can be increased by division in spring.

Some of the best varieties are: *O. vernus*, with violet and blue flowers in April and May, grows about one foot high. *O. v. roseus* also flowers at the same time as *O. vernus*. It grows about fifteen inches high and is suited for the front of the border, where a good clump makes a pretty show; it is one of the nicest spring-flowering plants we have. *O. aurantiacus* is of spreading growth, with pale green foliage and orange flowers that open in June. *O. varius* is a charming plant, growing about eighteen inches to two feet high. It has long, narrow, glaucous leaves, and bears spikes of sulphur and orange red flowers, an uncommon combination of colour. *O. lathyroides* is a plant that should be in every collection. It is a strong, erect grower, 2 feet to 3 feet in height, and bears spikes of lovely deep blue flowers in June and July. This variety is easily raised from seed, making nice plants the second season; they vary slightly in colour, however.

E. G. DAVISON.
Westwick Gardens, Norwich.

SOME GOOD UNCOMMON HARDY PLANTS.

***Sedum amplexicaule*.**—A very uncommon and most interesting *Sedum*. I saw it for the first time in Mr. Simpson Hayward's lovely rock garden near Stow-on-the-Wold, and I believe he was the collector of this gem. It is a miniature *Sedum*, with lovely glaucous foliage and clear yellow flowers; very valuable for the moraine. At certain periods of the year it curls up like the *Rose of Jericho* and appears quite dead, and in spring it breaks out again and thrives beautifully. Propagated by division. Flowers in June.

***Phlox subulata* Lady Thiselton-Dyer.**—Undoubtedly the gem of *subulata* *Phloxes* after *Phlox Vivid*, from which it is quite distinct. The flowers are a beautiful rose pink, with a distinct carmine eye. They are smaller than those of *P. Vivid*, but are much more freely produced. Easily propagated by cuttings or layers. Flowers in May.

***Sedum Willisii*.**—A good and uncommon *Sedum*, with foliage very like *Sedum obtusatum*, but it is of quite prostrate habit and has clear yellow flowers, which are very effective upon the red-tinted foliage. Flowers in June. Propagated by division.

***Dianthus deltoides* × *cæsius*.**—A good new *Dianthus*. A very healthy grower and showing distinctly both of the parents. It grows about nine inches high, with flowers much darker than *D. cæsius* and not fimbriated. Flowers in June and easily propagated by cuttings.

Anthemis cupaniana.—For a bold effect on a large rockery this cannot be surpassed. In general appearance it resembles a bedding Marguerite. It has a prostrate habit and nice grey foliage; very free-growing. Flowers in May, when the plant is covered with pure white blossoms. Propagated by cuttings.

Anthemis nobilis flore pleno.—A plant that will rival, if not surpass, the ordinary Pearl (*Achillea Ptarmica flore pleno*). It is of neat habit and suitable for the rockery. About one foot in height and covered with double Daisy-like flowers about three-quarters of an inch in diameter. A very continuous flowerer and a very showy plant. Flowers in June and July. Propagated easily by cuttings.

Epilobium macropus New Zealand.—A gem among miniature Epilobiums, with neat foliage, dark in colour, marbled with white. The flowers are white, about half an inch in diameter, and very floriferous. It far surpasses in every way E.

of flowers, many of them actually grown by those champions of the past—Hepworth, Holmes, Mellor and Gill. There was Hand Drum (*Andromeda*), which had probably been covered and uncovered again and again by old George (Gill) as he sat in his little workshop thinking partly of his boots and partly of the weather. Every shower of rain and every gleam of sun the plodding enthusiast noted, and then with almost electric swiftness he would run out and give his beloved blooms the exact treatment they required.

The room was the same. The flowers were the same. Yet perhaps not altogether. Were there any breeders there in the days of long ago? Even now, stern old James Knowles will not countenance them in his garden. This ancient veteran won the copper kettle (the blue ribbon of Tulipdom) in 1860 with the celebrated Polyphemus. With him as it was then, so it must be now, and so it ever will be; hence I rather think the advent of the breeder (or self colour) in such

competitors. Up above Messrs. Needham and Netherwood adjudicated, and as the prizes were awarded, down the successful pan or bottle was sent for their approval or disapproval. History does not relate what would happen if it was the latter. Were they all James Knowles's, there would be something "strong" said, I am sure, and Mr. Needham would have got it worse than he did when the Peggs (a variety called Elizabeth Pegg) he kindly sent as a present did not turn out all that they were expected to do.

The single bloom, or what may be called the bottle, classes are, naturally, judged according to Tulip custom. This is peculiar, as far as I know, to the flower, and not to Wakefield. Still, a brief explanation may be interesting. No one may take more than two prizes in any one class, but he may enter as many blooms as he likes. Frequently a man will put up ten or a dozen. What happens then is this: Each lot is arranged in rows, as may be seen behind the front row of prize-winners on this page. The judges select from everyone's lot the best two. When these are all picked out, the best four, six, or eight, as the case may be, are picked out and judged in the usual way. Naturally, judging is a long process. This particular show suffered, I am sorry to say, from the vagaries of our changeable climate. Fifteen members had entered and duly paid up their 4s. When they met in early May, they had little but hard, green buds, and it was settled to have a late date. A short spell of hot, bright, dry weather came. Everyone's blooms were hurried out in a half-grown state. Very many were entirely spoiled, and so only nine out of the fifteen actually staged.

The large silver medal for the best pan of six was won by the secretary (Mr. Irving Whitworth). He had a grand example of Coningsby Castle, a feathered byl'doemen, which had just passed its best, or it would have won the silver Rose bowl for the best flower in the whole show. His success would have been popular. He is, comparatively and figuratively speaking, a young grower. Thirteen years ago he only looked at them over a gate as they were blooming in a neighbour's garden. With true missionary zeal, that aforesaid neighbour set him up with a small collection, and ever since he has been a keen cultivator, while six years back he took over the secretarial office from Mr. Jesse Hardwick, who had to relinquish it owing to advancing years, but who was still hale and hearty, and who on this occasion (June 2) celebrated his forty-fourth time of exhibiting by winning the prizes for the best flamed and the best breeder with magnificently-coloured examples of Sir Joseph Paxton, grown in his quarry garden at Normanton. The best "feather" was a sweet little example of William Wilson, a lovely bizarre, with blackish brown markings on lemon yellow. The Tulip Society of Wakefield can justly boast of its ancient lineage, its famous names (among which that of Hepworth is still one to conjure with) and its strains. The Wakefield Paxton at its best is simply grand, and even now knows no superior. I fully appreciate all this; but regarding the society with the practical eye of matter-of-fact utility, I venture to think that by no means the least important reason which justly fills it with pardonable pride is the part it must play in the lives of the humble toilers, who compose 95 per cent. of its membership. Long life to the society; a long term of office to the secretary; a long list of keen members; many imitators. JOSEPH JACOB.

AN OLD-FASHIONED TULIP SHOW AT WAKEFIELD.

nimmularbolus and E. Hectori. It loves a moist, shady soil, flowers in July, and is easily propagated by division. E. C. BOWELL.

NOTES ON TULIPS.

I HAVE never had a more interesting floral experience than that which it was my good fortune to have on Monday, the second day of the present month of June. I then attended as an honoured guest the show of the Wakefield Amateur Tulip Society. For seventy-eight years without a single break this annual show has been one of the more or less important events in the life of this city, or, as I would prefer to call it, this ancient town. Seventy-eight years prepares us for something old, and in very truth it almost seems, looking back on the day, that I was the only modern thing there. There was the same old venue, the big room of the Brunswick Hotel. There were the same old varieties

numbers as the present schedule provides for is one of those modern innovations which would make many now dead and gone turn in their graves at the sad falling from grace of their spiritual descendants. Yes; the same old room. Almost the same old flowers; the same old bottles. One very old bottle, it is interesting to observe, was placed in front of one of the "pans" (the technical word in Tulipise for stand, probably dating back to a time when the receptacles for showing the threes and sixes in ware of earthenware) has certainly been in existence for a hundred years, probably many more, for they were well used when Abraham Holmes, the Parish Clerk, took over the duties of the secretaryship in 1835 and dated everything from his acceptance of office. Even the modern octagonal ones, Jesse Hardwick, an ex-secretary, told me had known thirty-five shows.

The judging, too, was a relic. Downstairs sat the secretary (Mr. Irving Whitworth) and the

GARDENING FOR BEGINNERS.

HOW TO LAYER STRAWBERRIES.

THE successful cultivator of these plants, whether in pots for forcing or in open borders in the garden, must not delay in getting a well-rooted stock of young plants. Frequently there is no attempt made to layer runners until all the fruits are gathered from the old plants. Such a delay is disastrous, because it is not possible to secure plants that are sufficiently well rooted to support a strong crown which will contain in embryo a large truss of flowers. Plants badly rooted cannot withstand forcing, and those in open borders cannot develop into fine specimens by the following fruiting season.

The Best Time to commence the work of layering is directly the first plants on the runners from the parent stock are large enough. Even if the old plants are ripening fruits, no damage need be done to the latter if ordinary care be taken.

How to Prepare for Layering.—The runners must not be touched before the actual day of layering, but both pots and compost should be got ready. Small but deep pots are best for both purposes—layering for forcing and also for new plantations—but where such pots are very scarce, small squares of turf which have been cut about three months are very serviceable. The pots must be quite clean, especially the insides of them, so that when turned out in due course the roots will not adhere to the sides and be broken off. The best compost is made up as follows: Turfy loam, two parts; leaf-soil, one part; horse-manure, which has been turned over daily for a week, one part. Some sand may be added, but it is not really necessary. Clear away weeds from around the parent plants, and then carefully draw out the best runners, removing every young plant from each runner except the one nearest the parent plant.

Fig. A.—No. 1 shows the parent plant, and Nos. 2, 2, the runners made ready for layering. No. 3 depicts how each young plant must be made secure in a small pot, either by pegging down or

VARIOUS METHODS OF LAYERING STRAWBERRIES.

by laying a fairly large, flat stone on it. Stones help to maintain moisture in the soil in the pots, and thus hasten root action. It is best to bury the pots well in the ground, as shown, because, if knocked over, the runners in them are loosened and delayed in forming roots. Water regularly in dry weather through a fine-rosed watering-can. No. 4 shows a square of turf—about four inches square—and No. 5 a small hole in the centre. Into this hole place the runner plant, and cover with fine soil and a stone. No. 6 depicts the young plant well rooted in the turf and ready for potting or planting out. Nos. 7 and 8 illustrate the deep pots, and No. 9 the runner plant severed from the parent when rooted, as shown in No. 8 pot.

Fig. B.—The new plantation is shown at No. 1, the plants being put out 18 inches apart in rows 2 feet asunder. Trench the ground 24 inches deep and well break up the lumps; if poor in

quality, add a liberal quantity of rotted manure, and immediately surface mulch with half-rotted manure.

Putting Layered Plants in Fruiting Pots.—No. 2 shows a fruiting pot 6½ inches across. Very careful crocking is essential. Many crocks need not be used, but those put in should be carefully placed. No. 3 depicts the ball of soil of a young plant laid on the rougher material in the large pot, and No. 4 the young plant as it appears when potted. Pot firmly, leaving a space of 1½ inches.

Autumn and Winter Positions.—Take the plants direct from the potting-bench to the sunniest position available, using boards to place the pots on. Give clear water only, but never neglect the watering, though it is unwise to unduly soak the soil. I water with diluted liquid manure when the pots are well filled with roots, so as to get the central crowns well plumped up. In winter place the pots close together in blocks, packing ashes, leaves, or litter round them, but not covering the tops, unless severe frosts occur. Boards fixed on edge, as shown at Nos. 5 and 6, will keep the block of plants and materials tidy. The central crown, No. 7, is the most important. All side crowns, Nos. 8, 8, must be removed while quite small. For the final potting use good loam and horse-manure. SOLENT.

SHADING THE GREENHOUSE.

VERY few greenhouses have a full complement of climbers on the roofs. It is not wise to have a too shady structure if fine pot plants are to be grown on the stages. The house, however, which has an almost bare roof—one devoid of climbers—is much hotter than a vinery, or even a plant stove. I strongly advise cultivators to lightly shade their bare-roofed greenhouses (except where Tomatoes are grown) and help the plants to make a healthy growth. There are many suitable compositions and materials advertised in *THE GARDEN*, and a good home-made shading is a mixture of butter-milk and whiting. Never use lime, as it destroys the paint. G. G.

A NEW STRAWBERRY PLANTATION.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Watering.—In the event of hot, dry weather, the recently-planted subjects will need a good deal of attention to give them a fair start. I do not favour too much artificial watering where it can be avoided, but one must not allow the plants to stand still or go back for the sake of a good soaking or two. Soft-growing subjects, such as Fuchsias and Colons, are very much benefited by a spray overhead each evening.

The Herbaceous Borders.

Pæonies and Aquilegias that are going out of bloom should have the stale flower-heads removed, in the case of the first-named shortening the leaf-growth back a little to give the other occupants of the borders more space.

Delphiniums throwing up their spikes should be neatly staked, and as these are fairly gross feeders, one or two waterings with liquid manure will do them good, or even on very light soil a mulching of short manure will prolong the flowering season considerably. This mulching of short manure may with advantage be given to many subjects, especially where the plants have not been shifted for a year or two, and Phloxes, Asters, Helianthus and Rudbeckias will all show their appreciation by an increased vigour in their growth and a longer season of blooming.

Violas.—To maintain a show of bloom through the summer, this beautiful subject must not be neglected. Dead blooms and seed-pods must be removed regularly, going over the plants at least once a week. A little Clay's Fertilizer sprinkled among the plants during showery weather will do much to help them maintain the deep green in their foliage which is such a grand offset or contrast to the flowers, no matter what colour these are.

Polyanthuses.—Many people sow these during February and March in boxes, and though they are somewhat slow-growing in the early stages, they should be quite ready for pricking out in beds on the border by this time.

Plants Under Glass.

Chrysanthemums.—If not already done, all plants should be spaced out and staked, giving as much room between them as space will allow. Two feet should be the minimum, though 3 feet each would be better, and in the case of decorative varieties and singles this would ensure them making nice shapely plants with well-ripened wood.

Stopping.—After this week no varieties of decorative and singles should be stopped, unless it is one or two of the dwarf-growing varieties which are to be flowered in small pots. A few of the Japanese varieties, such as J. H. Silsbury, Master James, White Queen, Queenie Chandler and others that are very early on crown-buds, if stopped now will give good flowers from November 1 to November 10.

Malmaison Carnations.—Plants from which the flowers have been cut may be placed in a cold frame preparatory to layering, giving them frequent syringings to clear them of spider, should any be in evidence.

Potting On.—Plants intended for potting on should also be cleaned, and if space is available in the houses or frames, they may be potted at once. Nine-inch pots should be large enough to carry them through the second season, using a moderately open compost, which should be well rammed to induce a very stocky growth. After potting, the plants should be lightly syringed overhead in the afternoon of very hot days, while the stages and paths should be frequently damped. Shade also must be given during the heat of the day, but only sufficient to keep the foliage a good colour and to keep the soil from drying out too quickly.

Tuberous Begonias that are well rooted and throwing up bloom should be fairly liberally fed with liquid manure, occasionally giving a pinch of guano to each plant. Give plenty of air and sufficient moisture to keep the plants in good health and free from insect pests. If thrips appear, fumigate lightly on two or three successive evenings, and this should quite rid them of this pest.

The Kitchen Garden.

Parsley.—A sowing should now be made to provide a supply for the late autumn and winter months. Should the weather be very dry, mats may be put over the seed-bed after watering in. This will help the germination, but the mats must be taken off as soon as the seedlings appear.

French Beans.—Continue to make sowings of these to keep up the supply into the autumn. Those coming into bearing must be liberally supplied with water, should the weather be hot and dry, or the crop will be a short one.

Runner Beans.—Early-planted batches or rows are growing freely, and mulching with long litter will help to conserve the moisture; and to get a good and early set of pods the plants must not be allowed to get dry, and a good syringing overhead will help them considerably.

Fruits Under Glass.

The Orchard-House.—Apples, Plums and Pears are fast swelling their fruit, and great care will be needed in watering. Liquid manure may be given freely, alternating this with an occasional dressing of artificial manure. The syringe must be freely used morning and evening to keep down insect pests, giving an abundance of air during the day. Unless it is necessary to hurry the trees, it is not advisable to shut the house up close either day or night.

Peaches ripening in pots may with advantage be placed on the shady side of the house, a steady ripening process often resulting in better-flavoured fruit.

Hardy Fruits.

Aphis.—Seldom have I known hardy fruit so badly infested with fly as during the past month, and though the trees have been syringed several times, they are still badly infested. About the only way of keeping it under is to frequently give the trees good washings down with the garden hose.

Strawberries.—Late varieties, such as Givon's Late Prolific, Laxton's Latest and Waterloo, will be greatly benefited by a good soaking or two of liquid manure. The former variety is probably the best of all late Strawberries, for though it does not give as heavy a crop at one time as do many other varieties, its continuity of fruiting makes it quite indispensable.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Lifting Narcissi.—The foliage of the earlier varieties will now have died down, and, if it is intended to lift any of them for the purpose of division, or in order to give them a change of soil, the sooner this is done after the foliage has thoroughly ripened the better. Spread the bulbs out in the sun, to perfect the ripening process, and then separate the offsets of varieties which it is intended to increase as far as possible. Keep in a cool, dry place till wanted for planting.

Top-dressing Phloxes.—The herbaceous Phloxes are surface rooters, and are much benefited by receiving a top-dressing during the course of the summer; the best time to apply it is just when the roots begin to show on the surface. Good loam forms the ideal top-dressing for them, but old potting soil, slightly enriched, will suit them quite well. Phloxes are among the first things to suffer for the lack of water in dry weather.

Sweet Violets.—Where young plantations of these have been made, they will now be growing freely. While I would recommend it for all and sundry, it is imperative in the case of plants intended for forcing that all runners be pinched out at an early stage.

The Rock Garden.

Propagating Cheiranthus.—What one may term the alpine Wallflowers are highly suitable for the rock garden. Those well known to me are C. Marshallii (deep orange), C. ochroleucus (pale yellow), and C. mutabilis, with its now improved form, C. m. purpurea. As soon as cuttings of these are obtainable, they should be taken, prepared, inserted in pots of sandy soil and stood in a close frame or pit.

The Wall Garden.

Thinning Seedlings.—Where seed was sown in the spring the seedlings will require thinning, and the extent to which this will have to be done will depend upon the character of the subject in hand and the results of germination. The work should be done during showery or dull weather, and if these conditions do not obtain, water both before and immediately after the operation.

Watering.—The next two months will be the most trying period of the year for the wall garden, and unless it takes the form of a retaining wall, a good deal of artificial watering will be required if the weather is at all dry.

Plants Under Glass.

Staking Chrysanthemums.—The work of final potting will now be over, and, if not already done, the plants should be placed in their summer quarters and fully staked. Those grown for large blooms may be placed in a line or lines running east and west, the stakes to be tied to a strand of wire stretched along the line. If a board on edge is run along in front of the pots, it will save much watering and keep the ball of soil more equable both as regards moisture and temperature. Bush plants can be arranged as indicated above, tying two or three of the stakes to the strand of wire.

Libonias.—*L. floribunda* and *L. penthosiensis*, although not showy, are two very attractive greenhouse sub-shrubs. Plants that were rooted early in spring should now be ready for a shift into 5-inch pots, which are quite large enough for these plants the first season. Equal parts of fibrous loam and good flaky leaf-mould with a little sand and a dash of bone-meal will form a suitable compost for them. A cold frame is the best place for them until the middle of September.

Salvia Heerii.—This *Salvia* is very showy in the conservatory in the spring. Cuttings rooted in heat in spring should from May onwards receive the same treatment as bush Chrysanthemums.

Fruits Under Glass.

Late Melons.—If vigorous plants are in readiness, a second batch may be planted to succeed the early crop. The glass and woodwork should be thoroughly cleaned before introducing the new soil and young plants.

Figs in Pots.—Unless they are pinched, Figs in pots are apt to make too gross growth, thus depriving the fruit of its due amount of nutriment. The cultivator must, of course, be guided by the vigour of the shoots. Continue to feed moderately till the fruits have attained their full size.

The Hardy Fruit Garden.

Summer Spraying.—Mr. E. Molyneux has forestalled me on this subject by his valuable contribution on page 272 of the issue of May 24, to which I would re-direct the attention of Apple-growers. It is by no means too late to give attention to this matter in Scotland, but no time should be lost.

Pinching.—Fruit trees often exhibit great irregularity of vigour. When this is the case, a judicious system of pinching should be adopted, as by this means not only is much waste of energy saved, but the balance of growth is more or less maintained.

The Vegetable Garden.

Planting Broccoli.—If not already done, the ground should be prepared for this crop and the work of planting proceeded with. Autumn Broccoli may be richly manured, but that for spring use should be planted in only moderately enriched soil, and in as open a situation as possible. Smear the roots with a mixture of soil, cow-manure and sulphur; this will help to ward off the attacks of the maggot.

Celery must on no account be allowed to become dry at the root, and if the foliage is dusted with soot from time to time, the Celery fly will, in all probability, be kept at bay.

Planting Leeks.—The main crop should now be ready for planting out. The Leek requires liberal cultivation and is partial to nitrogenous manures. Length of blanch is the thing to be aimed at, and this can be obtained by drawing drills as for Potatoes. Then plant with a blunt dibble in the bottom of the drills, make deep holes, and only fill in sufficient soil to cover the roots.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

**ANSWERS
TO CORRESPONDENTS.**

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SPOTS ON DELPHINIUM LEAVES (G. R. J.).—The dark spots are minute particles of soot. The foliage appears to have been damaged by water containing poisonous gases in solution, such as is very frequently the case where smelting furnace flames escape into the air.

PYRETHRUMS DAMAGED (Ascot).—We suspect an insect is laying its eggs in the stems of the Pyrethrums, but they are in too dried a condition to enable us to say with certainty what the cause may be. Can you watch after dark and send us further specimens, packed so that they will not dry up?

SWEET PEAS FOR EXHIBITION (S. C.).—As far as exhibiting is concerned, our Sweet Peas are, with four exceptions, hopelessly out of date, and improvements might easily be made for garden decoration. Since you do not purpose to exhibit until next year, your best plan will be to wait until the end of August and write again. The experience of the present season will enable an up-to-date selection to be given.

VIOLETS GONE WRONG (M. H. A.).—The Violets are attacked by the very troublesome fungus *Phyllosticta violæ*. This fungus has sticky spores, which are liable to be carried on cuttings and to infest frames where the plants are grown, and it is exceedingly difficult to eradicate when once it has got a footing. The best means to adopt is probably to dig up and burn all the affected plants and start afresh, but if it is desired to try to keep them going, spraying with potassium sulphide (1oz. to three gallons of water) will probably be the best thing to do.

DISEASE IN VIOLAS (Hford).—Violas not infrequently suffer from the attack of a fungus belonging to the genus *Fusarium*, which causes the sudden wilting and death of the plant in the way you describe. Nothing can be done when once a plant is attacked, for the fungus is inside the plant and quite inaccessible. Spraying is useless, but the fungus gains entrance from the soil, and the growth of Violas year after year in the same soil is very liable to bring about the spread of the trouble, as is propagation in old soil. This points the way to prevention, and the use of lime in the soil will also be an aid.

THE GREENHOUSE.

CHRYSANTHEMUM FLY (Hford).—The plants are attacked by the larvæ of the Chrysanthemum fly (*Naptomyza lateralis*), which burrows into the leaf. The fly is a small, two-winged one, and its visits may be checked, to some extent at least, by spraying the plant, say, in April (at end) with a paraffin emulsion. Where only a few plants are to be dealt with, pinching the affected leaves between the fingers and thumb will kill the larvæ, and it is said that nicotine washes will also effect the same result by acting through the epidermis.

CHRYSANTHEMUMS INFESTED BY THE LEAF-MINING MAGGOT (W. G.).—During the past two years the leaf-mining maggot has done much damage to Chrysanthemums in different parts of the country. Some varieties are more liable to attack than others. It is well to carefully examine the leaves weekly from their cutting stage, and crush any maggots found; also to syringe the foliage every fortnight with petroleum emulsion at the rate of a wineglassful to a gallon of water. The oil must be vigorously stirred in the water, and when applying the liquid, forcibly return two syringefuls to the vessel to every syringeful sprayed on the leaves. The best time for the syringing to be done is during the evening. This mixture should be applied to unaffected as well as to affected plants.

DISEASED LEAVES OF CHRYSANTHEMUMS (B. Worle).—The leaves which you send for our inspection are badly attacked by "rust." All leaves that are in a similar condition should be removed and burned at once, as they will, if left on the stems, soon shrivel up and spread the disease to sound leaves. Procure from a chemist an ounce of sulphide of potassium. Dissolve half

the quantity in rain-water, and then add it to half a gallon of rain-water, syringing the solution on every leaf and portion on both sides. To accomplish this, lay the plants on their sides on a mat, turning each specimen over until all parts are thoroughly wetted. The remaining half an ounce of sulphide should also be dissolved in a similar quantity of water and kept in an earthenware vessel, to be syringed on the plants fortnightly as they stand in the rows. This will tend to keep the leaves free from rust.

ORCHIDS FOR A COOL GREENHOUSE (Iron).—To be successful with Orchids, the temperature should not fall below 45° or 50° Fahr., the former figures only being recorded during severe weather, when no harm will accrue if the atmosphere is fairly dry. Unless you can command the above temperatures, we do not advise you to begin growing Orchids. If you can, you might begin with a small quantity of *Odontoglossum crispum*, as two plants rarely produce flowers exactly alike; also *Odontoglossum luteo-purpureum*, *unabile*, *triumphans*, *Pescatorei*, *mevium*, *andersonianum*, *gloriosum*, *Hallii*, *wilckeanum*, *perulatum* and *ardentissimum*, while others could be bought in flower: *Cypripedium insigne* varieties, *Cymbidium lowianum*, *Lycaste Skinneri*, *Masdevallia*, *coccinea* varieties; *Disa Luna*, *D. sagittalis*, *Pleurothallis Roezlii*, *Odontodia Charlesworthii*, *O. Bradshawii*, *O. lambeauianum*, *Zygopetalum Mackayi*, *Epidendrum vitellinum* and *Cattleya citrina*.

HIPPEASTRUMS (H. C. S.).—After flowering, *Hippeastrums* should be encouraged to grow freely, as upon this the future display of blossoms depends. They must be removed into a structure kept warmer than an ordinary greenhouse, the best place being the coolest part of the stove or an intermediate house. It is very necessary to keep them well supplied with water, but an excess must, of course, be avoided. An occasional dose of liquid manure, or one of the many concentrated plant foods now so popular, will be beneficial. With this treatment the plants will grow freely and the bulbs increase in size. By the end of July or thereabouts they will have perfected their growth, or nearly so, when they may be removed to a frame or a greenhouse. As they will have been shaded when in the warmer structure, it will be necessary to continue this for a little time till the tissues of the leaves get firm. Then they may be fully exposed to the sun, in order to ripen the bulbs. As the leaves turn yellow and show signs of going to rest, the water supply must be lessened, and when the bulbs are absolutely dormant it may be discontinued for a time. They should be kept during the winter in a temperature of 50° to 60°, and about the end of January a little water may be given, to be increased as the plants grow.

DWARFED JAPANESE TREES (E. W. R. P.).—We do not know of any book dealing with the Japanese method of dwarfing trees, but a good work on the different species of Cactas is "Cactas Culture for Amateurs," by W. Watson, Curator of the Botanic Gardens, Kew. Briefly, the Japanese dwarf trees are obtained by growing them in such a manner that they only receive sufficient nourishment to keep them alive. This practice is followed from the earliest stages, and commences, in the case of many plants raised from seed, by shortening back the tap root and leaving just a few fibres for the plant to obtain its nourishment therefrom. Potting in shallow receptacles and using poor soils are also objects towards the same end. The result is that the plant falls, as it were, into a moribund condition, and though enough vitality is retained for the usual seasons of growth and rest to be followed, yet it is so far stunted as to be quite unable to shake this off and resume its natural style of growth. The Japanese, from their long years of experience, are very skilful in the production of these dwarf trees, and here they are admired by many as curiosities, though the general taste is more in favour of naturally-grown subjects. These dwarf trees, when grown in this country, should be well supplied with water when necessary, but stimulating manures must be avoided.

ROSE GARDEN.

LEAF-CURL (H. G.).—The trouble arises from the action of the larvæ of a sawfly, and it is done by them when immature. Spraying with nicotine has been found to kill the larvæ, but it is best to pick off the curled leaves as soon as detected. No doubt the pest is first imported into the garden from soil adhering to roots of Roses that have been previously attacked. It is a troublesome pest, and where very prevalent we should advise replanting in the autumn, taking care to wash off the soil from the roots and remove to quite new soil.

ROSES FAILING (Lieutenant-Colonel H. F. D.).—The shoots sent are exceedingly pithy, and should certainly have been cut hard back in spring. Probably, being so pithy, they suffered from winter frosts, which, although not severe, were quite enough to damage such growths. This pithiness of the wood would naturally affect the buds, for they cannot receive their natural food. Whether this state of things is owing to faulty culture we cannot say, but it looks much like a case of overdosing with some chemical manure that encourages this sort of growth instead of a growth of a more solid nature. Too much, nitrogenous food will produce this sappy wood, and the frequent applications of insecticides only tend to aggravate matters, for, naturally, the liquid finds its way down to the roots. We should advise hard cutting back of all such wood, and probably the basal eyes will be all right and will quickly start, so that you will have a good autumnal display.

FRUIT GARDEN.

LEAVES OF PEAR TREE FOR INSPECTION (M. M.).—The symptoms point to the trees being exposed to cold winds. Shelter is an important thing with many Pears, not only for the protection of the foliage, but also as an aid to pollination, since bees do not care to visit flowers in windy weather.

BIG-BUD IN BLACK CURRANTS (J. A. B.).—The Black Currants are affected with "big-bud." Pick off and burn all the affected buds in winter, so as to remove as many of the mites that cause the trouble as possible, and spray the plants with Quassa and soft soap three times at fortnightly intervals, beginning at the end of April next. The Beech leaves have been injured either by draught or dry or cold winds.

GOOSEBERRIES GONE WRONG (R. R. S.).—We find neither fungus nor insect on the plants to account for the trouble of which you complain. They appear to us to be suffering from lack of sufficient water, and we would suspect they have insufficient roots to supply the demand made by the foliage when the sun becomes hot upon them. They have apparently grown very rapidly. Does the soil ever become water-logged?

GROWTHS ON VINE LEAVES (Black Hambro').—The curious appearance of the Vine foliage is due to the growth of warts upon it, produced by the presence of too much moisture in the air. This checks the normal loss of water from the leaves and brings about a condition of great pressure in certain of the cells, resulting in their greatly increased growth and the formation of warts. They are signs of improper conditions, and point the way to a remedy.

BARK OF APPLE TREES STRIPPED BY RABBITS OR HARES (J. M. C.).—If the bark has been completely stripped from round the stems of the trees, nothing you can do will avail to make them useful and satisfactory trees afterwards, although they may perhaps linger on for some years as wrecks. But if there is a part of the bark remaining, say, on one or two sides, they will have a better chance of living, as new bark in time will take the place of the old. The wisest thing to do in the case of badly-stripped trees like yours is to grub them up and replant in autumn with healthy trees.

RASPBERRIES AND GOOSEBERRIES DISEASED (M. H.).—The Raspberries are attacked by the fungus *Hendersonia rubi*, as you may see by the pale dead spots on the canes covered with the tiny black fruit of the fungus. All affected canes should be removed and burned, and the remaining plants sprayed with Bordeaux mixture. The Gooseberries are affected with the black, a disease due to a fungus which does not fruit until it has killed a branch. All dead branches should be immediately removed and burned. Spraying in this case will be of little use. The yellow-flowered annual is *Limnanthes Douglasii*, a good bee flower.

MELONS CRACKING AND BECOMING SPOTTED (A. W.).—The Melon is one of the easiest of all fruits to grow, provided the grower has some sound knowledge and experience to guide him in the work; but once the fruit goes wrong through faulty treatment, it seldom does any good afterwards. The cause of cracking in Melons is too much water applied to the roots and too humid and close an atmosphere. Give more air and keep the soil moderately dry for a time, and notice the result. If there is no improvement, it will be better to pull up the plants and start again with fresh ones. If you decide to do this and will let us know, we will try to help you with the new crop by giving a few details as to culture.

CUSTARD APPLE SEED (T. J. L.).—The Custard Apple is the fruit of *Anona squamosa*. It makes a bush-like tree, attaining to a height of about fifteen feet. The tree will take at least three years to grow from seed before any fruit may be expected. When the fruit is ripe it is fleshy, the pulp being yellow and so soft that it is difficult to handle without bruising. The flavour of the fruit has been likened to that of Raspberries and cream. In tropical countries it is much appreciated and consumed. To grow it to perfection in this country it would require a well-heated greenhouse to itself; but the fruit is not particularly cared for here, and certainly not deemed of sufficient importance to have a glasshouse devoted to its growth. The way to grow the seedlings is to pot them and grow them on in heat during the summer, with cooler treatment in winter. The tree is well branched and clothed with leathery, oblong leaves, in the axils of which are borne in spring greenish, fleshy flowers about one inch across. The soil that suits it well is the same as you would use for growing Peach trees in pots.

ESPALIER PEAR TREES NOT BEARING (X. M. D.).—The varieties are fairly consistent bearers, and therefore the fault is not to be looked for in the varieties. The Pears (or most of the varieties) are strong-growing trees, and it often happens that if means are not taken in good time to moderate such strong growth, it will so continue one year after another, the tree remaining practically barren all the time. In all such cases root-pruning should be resorted to. If properly carried out it can do no harm, and in ninety-nine cases out of a hundred it proves effective in bringing the trees into a fruitful condition. With reference to the fruit of your Magnate Pear tree shrivelling and dropping, this is most unusual, for this variety is one of the most satisfactory croppers we have. Can it be that the roots are dry at any time? Give the tree a real good soaking now, and then a mulch of rotten manure on the surface 3 inches deep. Water it again a fortnight hence over the manure, and once more before the fruit shows signs of ripening. It is a good plan to give such fruit trees a thorough irrigation of manure-water in

the winter as soon as the leaves have fallen. It fertilises the soil and nourishes the roots.

SCAB ON YOUNG PEACH FRUIT (*J. R. R.*).—Judging by the sample of foliage sent, your tree is in a feeble state of health, but the cause of the injury to the fruit is "scalding" (in garden parlance). This is brought about by bright gleams of sunshine shining on the fruit while it is damp from late spraying, and insufficient ventilation. Do not try to force the tree's growth, but let it come as naturally and gradually as possible, giving plenty of air in fine weather, day and night, but, of course, in cold weather not so much. In this way we hope the fruit which is left and which is healthy may develop and ripen all right, but there is no hope for that which is diseased like the sample. Syringe the trees in the afternoon of fine days, about 4 p.m., but not in the morning. Water with care. Do not let the soil be waterlogged or too dry at any time. The best way to bring your tree back to health will be by lifting it bodily and replanting at the end of October in good, fairly heavy maiden turfy loam, adding a gallon of lime and a quart of bone-meal to each barrow-load of the loam. Tread the soil firmly over the roots when planting. This replanting, if carefully done, need not prevent the tree from bearing next year. Let the points of all the roots be slightly shortened at the time of replanting.

TO GROW MELONS IN A FRAME (*E. C.*).—The Melon should be planted and grown very much like a Cucumber, the chief difference being that heavier loam should be used and no manure mixed with the soil. The soil, after planting, should also be pressed down more firmly round the roots than is advisable for the Cucumber. Two plants should be planted together in the centre of a one-light frame (10 inches from the glass). When each young plant has formed a stem, say, of 4 inches in height, let the top of the stem be stopped by pinching off the top with the finger and thumb. The result of doing this will be that two new shoots will emit from the stem lower down. These will form the two main branches of the plants, and be the ones which will bear fruit. These branches will trail on the surface of the soil. As soon as they have attained a length of 15 inches, let the extreme points of each be stopped, as the young shoot was stopped before. The result of this stopping will be that two or three other shoots will issue out of the side of these branches. These are called lateral shoots, and these are the shoots which will bear the fruit. By the time these side shoots are 7 inches long, each one will show a female blossom. This is distinguished from the male blossom by having a swelling at the bottom, and is easily known. As soon as you can secure two or three of these female blossoms expanded on these laterals at the same time, then is the time to fertilise the flowers with the pollen of the male blossom, this being applied to the stigma (the centre column of the female blossom). This should be done at midday, when the pollen and the flowers are quite dry.

KITCHEN GARDEN.

WORMS ATTACKING VEGETABLES (*E. R.*).—The worms are mostly white worms which are allied to earth-worms, but, unlike the latter, frequently cause considerable damage to plant roots. We think a dressing of lime to the soil is called for; but meantime some good may be done by watering the plants with lime-water.

ASPARAGUS BITTER (*An Outsider*).—The cause of the bitterness, we think, is undoubtedly due to injury to the young growth by frost. While there is danger of frost you should inspect your beds every morning and cut off all the grass which is fit to cut, and that which is too small to cut you should cover over with some soil from the surface of the bed in order to protect it.

MISCELLANEOUS.

CHANGING THE COLOUR OF FLOWERS (*A. H.*).—Many aniline dyes may be used for giving flowers unnatural colours, either by dipping the flowers completely in or by allowing them to soak up the dye.

HARD WATER (*W. S.*).—Your water is probably hard because of the amount of chalk it holds in solution. If this is so, it may be materially softened by boiling, or by the addition of a small quantity of quicklime to the tank in which it is kept before use in the house.

ROSES AND IRISES ATTACKED BY A FUNGUS (*J. S.*).—The Roses and the Irises are attacked by the same fungus, *Botrytis cinerea*. This fungus usually attacks plants that are rather ripe in their growth, or that have been checked by a frost. Extra liberal manuring or growing the plants in rich soil, which encourages sappy growth, lays the plants open to attack. All diseased parts should be removed and burned.

INJURY TO APPLE BLOSSOM (*Apple*).—The Apple flowers are not attacked by the Apple-blossom weevil, but probably by the Apple Psylla. This pest lays its eggs in autumn on the young twigs, and it is very likely to be carried from one place to another on the trees in this form. No Psyllas were present when the clusters reached us, but the appearance of the dead flowers suggested that attack.

BOTTLING FRUITS AND VEGETABLES (*W. H. C.*).—All vegetables and fruits should be gathered dry. Peas, young and freshly gathered, should be shelled and thrown into boiling water with a little salt for five minutes. Fill the bottles with Peas, filling with the water they were boiled in. Put in the steriliser and gradually heat to boiling point. Screw the cap down tightly when taken out. Treat Asparagus in the same manner. Cut the stalks to suit the length of the bottle. Strawberries should be rather under-ripe and packed closely in the bottles. Fill, when

cold, with syrup made by dissolving a pound of sugar in two quarts of water. Sterilise as advised. Gooseberries may be treated with plain water or syrup, preferably the latter. Use the fruit young.

PONDWEED (*H. S. B.*).—You can arrive at the approximate cubical contents of your pond by taking the average depth of water in feet and multiplying it with the square of the surface. As the pond varies in depth, you will find a difficulty in getting the exact cubical contents of water; but as you can use copper sulphate with safety at any strength between 1 in 750,000 and 1 in 1,000,000, there is a wide margin for any inaccuracy. Copper sulphate is even effective in killing scum at less strength than 1 in 1,000,000, though it is advisable to keep to that strength, or as near as possible.

INJURY TO LEAVES (*S. C. R.*).—Your soil is probably insufficiently drained and cold in spring. This would fully account for the yellow colour of the rambler Rose shoots. Attention should be paid to drainage and to lightening the soil. If you can make it a little darker by the addition of soot, it would probably help matters. The Plum is attacked by silver-leaf. It would be well to cut out the affected parts completely and burn them. Affected branches very rarely recover and scarcely ever fruit, while the fungus which is the cause of the trouble spreads from diseased branches after they are dead.

NAMES OF PLANTS.—*R. K. H.*—Sitka Spruce (*Picea sitchensis*, sometimes called *Picea Menziesii*).—*M. R. P.*—*Collinsia bicolor*.—*Parnell, Bourne-mouth*.—*Lonicera involucrata*.—*G. E. C.*—*Panicum arvense*.—*The Lady Kennedy*.—*Pyrus Aria* (White Beam).—*R. M.*—1, Red flower, *Crinodendron hookerianum* syn. *Trienspidaria hexapetala*; 2, *Rhamnus catharticus*.—*J. C.*, *Kintoch-leeven*.—1, *Galium saxatile*; 2, *Trientalis europaea*; 3, *Pedicularis sylvatica*; 4, *Lysimachia nemorosum*; 5, *Geum rivale*; 6, *Euphorbia* species, too scrappy to identify.—*G. R.*, *N. Wales*.—1, *Ajuga reptans*; 2, *Helianthemum vulgare*; 3, *Polygala vulgaris*; 4, *Coronilla cappadocica*; 5, *Forsythia* species; 6, *Symphoricarpos racemosus*.—*"Jim"*.—1, *Davallia mooreana*; 2, *Adiantum formosum*; 3, *Polypodium aureum*; 4, *Davallia elegans* variety; 5, *Gymnogramme wettenhalliana*; 6, *Codium variegatum* variety; 7, *Gymnogramme chrysophylla*; 8, *Phyllanthus nirousus*; 9, *Acalypha macrostachys* (musicaea); 10, *Dracena terminalis* variety; 11, *Davallia elegans*; 12, *Gymnogramme pulchella*.

BOOKS.

The Genus Iris.*—"A great book, a great evil," said the ancient Greek, and the little that I can detect of evil in this fine addition to the library of the botanist and the gardener is chiefly connected with its magnitude. It refuses to enter a shelf that comfortably accommodates such fine folios as Andrews' "Heaths" and a tall copy of the 1768 edition of Miller's "Gardeners' Dictionary," being a head taller than either. Even where extra head space has been prepared for the "Hortus Elthamensis," the width of these Iris portraits is such that the door cannot shut upon them. The magnitude of price exists only so long as the book is regarded from its outside. Once open its pages and realise the labour, research and voyages necessary for its completeness and original authority, taste the delight of its exquisitely delicate and accurate illustrations, and you are like the swimmer who, braver than the rest, first plunges into the stream and instantly calls to the others looking at the apparently cold water, "Come on; it's just lovely." The ample pages when open provide the reader with the possibility of good clear type and division under headings, so well spaced that a glance is sufficient to give you the one you want. Thus, after the recognised name of each species we get references to its published descriptions, and should it be figured as well, an asterisk points it out. Then in order follow a list of synonyms, distribution, Latin diagnosis, description in English and a final division for observations. These are in most cases delightful records of the author's personal experience in visits to the plants' native homes, or efforts, successful or otherwise, to obtain living material; but especially noteworthy and useful are the many thorough and practical notes on cultivation.

* "The Genus Iris," by W. R. Dykes; price 6 guineas net. Cambridge University Press.

These are, perhaps, one of the most marked features of this book. It is so rare to find a botanist who can produce such a systematic monograph and also has the true gardener's enthusiasm for the beauty of the plant, and the patience and perseverance that lead to the discovery of the individual idiosyncrasies of the wayward when under cultivation. As an instance of this I may quote the following: "There appear to be two main forms of *I. ruthenica*; one has almost rigid leaves and flowers freely, while the other has flimsy, largely prostrate, foliage. It flowers only exceedingly rarely—at any rate in the dry hot soil of Surrey, although in moister and richer conditions, it is said to flower well and even to produce a second crop of flowers in the autumn." Such a simple rule should banish the flaccid-leaved, barren patches from all but the gardens of the students of forms. It would be easy to instance further rich fruits gathered from the author's personal observations of his plants, but space will admit of but three. By raising seedlings he has proved that many forms that breed true from seed should be regarded as Mendelian recessives, and not as subspecies. He instances the white forms of *I. tectorum*, *I. sibirica* and *I. orientalis*, the crimson *I. versicolor kermesina*, and that form of *I. Pseudacorus* in which the usual brown markings are absent.

The second discovery is so interesting and useful that I give the author's own words: "Nature has provided us with one infallible sign, which will show us whether an Iris is a native of a dry or a wet soil. This will be seen if leaves of *I. Pseudacorus* or *I. versicolor* are held up to the light side by side with a leaf of a *Pogoniris*, for instance, of *I. germanica*. The latter will appear of a uniform green, but the former will show a number of minute blackish spots, which on microscopical examination prove to be due to the fact that at these points the vertical channels in the tissue of the leaves are blocked by growths of apparently the same structure as that which surrounds the passages. The increased thickness of the structure at these points produces the appearance of the black spots."

As another instance of the value of this book to the cultivator of Irises, we may take the notes on the Californian group, so beautiful, yet so rarely seen. The author tells us two causes prevent their generally successful cultivation—soil that is strong in lime, and the paucity of their root-fibres, which makes transplantation uncertain—and he gives most useful hints, drawn from experience, as to the methods by which he has successfully raised them from seed and established them in permanent quarters. The careful study of this book would greatly enlarge the views and collections of Iris growers. Too many good gardens contain few varieties and species other than the florists' forms of bearded Irises so often erroneously classed as "German" Irises, whose main display is confined to late May and early June, leaving out those that would furnish blooms from the late autumn (I always expect and often get *I. unguicularis* blooms in the first week of October) to the middle of July, when the Japanese Irises close the normal Iris season. The Iris has been aptly termed the "poor man's Orchid," but no one who gardens in the open air should neglect this fine plant, and henceforward none should be content with less than an eight months' succession of Iris flowers, who can give space and attention to them and will put in practice the good advice so richly stored in this book, which is beyond doubt a great one for the practical gardener.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Next Year's Daffodil Show in London.—April 21 and 22 are the dates fixed by the Council of the Royal Horticultural Society for their Daffodil show next year. We understand that the schedule of the show will be ready shortly.

Meconopsis paniculata.—Like *M. Wallichii*, which in general appearance it much resembles, this plant is worth growing for its foliage alone; but when it opens its pale lemon cup-shaped flowers in June or early July it is doubly captivating. It is not too late to sow seed of it in a cool frame, where the plants should remain till spring.

Forthcoming Saxifrage Conference.—The President and Council of the Royal Horticultural Society have decided to hold a Conference on Saxifrages in the spring or early summer of 1915. Fuller particulars will be issued in due course, but notice is given thus early in order that those interested in this family of plants may have time to prepare material. The Council will be pleased to hear from any willing to contribute a paper at the Conference or to take part in any way.

A Beautiful New Garden Rose.—One of the best garden Roses of recent introduction that we know is *Lady Alice Stanley*, a Hybrid Tea that emanated from the Emerald Isle in 1909. This Rose makes a fine spreading bush, and its glorious solitary flowers are produced on stout, erect stems. The blooms are of silvery pink colour, the reverse of the petals being deep, glowing rose. This combination is particularly charming. The flowers are large, fragrant, and last in good condition for a long time after they are fully expanded, of which stage they remind us of refined *Pæonies*.

A Good Early Pea.—One of the best early Peas that we have ever grown is *Early Morn*, a wrinkle-seeded variety of splendid quality, with excellent cropping powers. Sown in the open on March 8, the plants gave a splendid lot of pods for picking on the 21st inst. This Pea has robust haulm of about three feet in height, and the pods are long and almost straight, the average number of Peas in each being nine. When cooked these are of a beautiful green tint, and the quality is all that one could wish. It is a Pea to note for sowing next year.

A Beautiful Rock Rose.—*Cistus Loretii* is one of the hardiest and best of the numerous Rock Roses, and it is a plant to include among subjects for dry, sunny banks. Of hybrid origin, it claims as parents two showy species in *C. ladaniferus* and *C. monspeliensis*. Mature plants attain a height of 4 feet with a similar diameter, and are prominent throughout the year by reason of their dark green leaves. It is, however, during early June that they are most attractive, for at that time they are covered with showy flowers. Each blossom is about two and a-half inches across, white, with a rich reddish blotch at the base of each petal. Cuttings of young

shoots root readily during summer if placed in sandy soil in a close frame, while the plant thrives in quite poor soil; in fact, it is a mistake to make the ground very rich for this or any other *Cistus*.

Single Roses Flowering Well.—The freedom with which the Dog Rose (*Rosa canina*) is flowering in the hedgerows of our country lanes is truly wonderful. We recently came across bushes of this Rose smothered with bloom on a lakeside with *Iris sibirica* in full flower on either side of it. The association of these plants and the colours produced were pleasing in the extreme. The Burnet or Scotch Rose (*R. spinosissima*) is likewise flowering with remarkable freedom, while the less hardy Cherokee Rose (*R. smica Anemone*) is flowering in some gardens better than it has ever been known to before.

The Prophet Flower.—This Oriental plant is often met with under the name of *Arnebia echioides*, although it is correctly known as *Macrotomia echioides*. It belongs to the Natural Order Boraginaceæ, but it is little like a Borage. The peculiarity of the plant is seen in the large, bright yellow flowers, which when first open have a purple maroon blotch at the base of each of the five petals. The remarkable thing is that the blotches, which are very conspicuous in the young flower, disappear as the flower matures. This is a subject worthy of a position in the rock garden, for it is both attractive and interesting. A sunny position and a sandy loamy soil suit it admirably.

Creosote Fumes and Plants.—Last week a correspondent wrote to say that he had recently had a new greenhouse built, and that the wooden staging had been treated with creosote. Tomato plants which had been placed in the house had suffered considerably, the leaves having curled up in an alarming manner. Apparently it is not generally known that the fumes of creosote, which are very penetrating, are injurious to plant-life, particularly in the confined atmosphere of a greenhouse. Wood that has been recently treated with this preservative ought to be kept away from plants of all kinds, though after several months its injurious properties appear to pass away.

Anchusa italica Dropmore Variety.—One of the most conspicuous herbaceous plants in flower at Kew early in June was this beautiful variety of the Italian Alkanet. It was planted about the grounds in large groups in several situations, notably near the T Range and Palm House, and beside the Lake in the Arboretum. Possibly it was seen to the best advantage in the latter place, for, looking across the Lake, in addition to the mass of blue on the bank there was the colour reflected in the water with a background of dark foliage trees. It is quite an easy plant to cultivate, and a stock of plants may be raised quickly by making cuttings of the stronger roots during spring or summer. Good loamy soil provides a suitable rooting medium, and a surface-dressing of manure in spring serves to keep the plants in good health.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Birds and Fruit-Nets.—Will you allow me to suggest to the bird-lovers among your readers that during the summer season they should make a point of periodically visiting their fruit-nets? and so ensure against such of our little songsters who may have been caught there dying a slow death by hunger and thirst. It is quite a common thing to find the dead body of a bird entangled in the meshes of a Strawberry-net, and one does not like to think of the lingering death by which the little thief has atoned for his very natural greediness.—Z.

Gloxinias for a Cool Greenhouse.—The writer of a note on this subject in "Notes of the Week," issue June 14, is quite right when he says that the tendency is to regard these plants as stove subjects. One of the best batches of plants I ever saw was grown in a cold frame during the summer months, in fine weather being fully exposed, as the lights were removed, and only taken to a cool greenhouse as the flowers developed. It was an experiment growing the plants so, occasioned by want of room, but quite a successful one. All the flower-stems were strong and upright, and the leaves thick and leathery, whereas many flowers grown on plants in hot stoves have to be supported.—G. G.

Musk Without Scent.—I read in a note in THE GARDEN of last week that you notice how scentless Musk has become. I believe I am right in saying that in England it has had no scent for the last five years or so. I have noticed this lack of scent in Devon, Hants, Worcestershire and various Midland Counties, and have been told of it by many friends living elsewhere. It occurred to me that perhaps the plant has acquired the habit of self-fertilisation. Should this be the case, its protoplasts would naturally leave off producing a volatile oil to attract insects. For the last three years I have watched Musk plants with interest in the counties I have named, and have never seen them visited by insects. Can this be the solution?—VICTORIA SLADE

The Long-Spurred Columbines.—I can very fully bear out all that is advanced in favour of these plants in "Notes of the Week," issue June 14. For more than ten years I had charge of a garden in which the Columbine was a favourite plant, and during that period there was a large border, about ten feet wide and sixty feet long, filled with them, besides clumps growing in the herbaceous borders. For many years previous to my charge the Columbines had been growing in the same border. I never dug up the clumps nor the border soil, all the attention given being confined to an annual surface mulch of rotted manure and loam in equal quantities, mixed. The original soil was of too light a nature to admit of the addition of leaf-soil. Every year seedlings appeared and, in due course, produced flowers of very beautiful colours. Perhaps the plants deserved better treatment, but they did remarkably well. The flowers were charming in vases.—G. G.

The Lackey Moth Caterpillar.—If one looks at the Hawthorn hedges about May or June one cannot fail to notice cobweb-like structures which cover many of the shoots, and also that these branches are practically destitute of leaves. The smaller of these tents belong to the caterpillar of the

ermine moth, while the larger kinds belong to that of the lackey moth. Both these, especially the latter, are also troublesome as regards Apple, Plum and other fruit trees. The illustration shows a typical, well-developed tent of the caterpillar of the lackey moth, taken from an Apple tree. It was about nine inches in length and remarkably strong. On studying the life-history of this pest we find that the moth lays its eggs on the young shoots of the trees in autumn in rings, and the number of eggs varies from forty to two hundred. They are greyish in colour, and are rather difficult to discern against the brown of the bark unless the tree is small. These eggs withstand all the rigours of winter, and hatch out towards the end of April. The young caterpillars are black with two yellow lines down the back, and we notice that they soon commence spinning a web so as to enclose a few leaves, on which they feed. As they grow, so the tent grows, and when they are about half

A TENT OF LACKEY MOTH CATERPILLARS.
THESE DO CONSIDERABLE DAMAGE TO
APPLE AND PLUM TREES.

an inch long they begin to spread about the tree, devouring the leaves, making a point, however, of always returning to the tent in the evening. On dull and wet days they remain in the tent. The full-grown caterpillar is about one and a-half inches long, and is rather gaudily coloured, having a ground colour of bluish grey with red and yellow stripes. About the middle of June the chrysalis is formed inside a silky cocoon, the outside of which is covered with a yellow powder. This cocoon is either suspended from a leaf or enclosed between two leaves. The moth usually appears in July and August and deposits its eggs, and so the trouble goes on. From this brief study of the life-history we see that the best means of destroying them (always, of course, presuming that it is in the majority of cases impossible to see the eggs) is to remove the tents in the evening or on a showery day, as at these times one could be practically certain that all the caterpillars would be caught.—H. BECKTON, *Donington, near Spalding.*

The Dwarf Mock Oranges.—I was pleased to see the note on these charming shrubs on page 309 of last week's issue. I grow them near the doors

and windows of the house, where the large kinds would take up too much room, and their fragrance is delightful. The hint to cut out old wood after flowering is a useful one that I hope to act upon.—A. B. ESSEX.

A Glorious Garden Pink.—Referring to your paragraph in "Notes of the Week" in last week's issue of THE GARDEN regarding Pink Gloriosa, last year I successfully layered about five hundred of this, as you truly state, glorious Pink; but my experience is that the plant undoubtedly requires protection in the winter. My plants were duly planted out on a warm border, and had last winter been a severe one, I should certainly have lost the whole of my stock. At the present time the plants are just recovering, and have flowered fairly freely, but mostly with very short stems. I may state they are growing in the neighbourhood of Richmond. After layering this season I intend planting them out in cold frames for the winter, and then plant out in early spring. I should be glad to hear other growers' experiences and opinions on this lovely new plant.—C. A. G. [The plants we have are growing in a warm border by the house, but facing east. This is in Essex. They have withstood two winters without protection.—E.P.]

Silver-Leaf Disease in Apple Trees.—I have noticed the increase of this disease in fruit trees more than ever this year. Is it not a fact, though, that this is so following a wet season? The disease, unfortunately, is not now confined to Plum trees, but is attacking Apple trees also. Last year I found two trees of Norfolk Beauty which had been grafted on to Warner's King five years previously, affected. Extra strong growth followed the grafting. The cause of this disease attacking these particular trees is very puzzling, as there are many more of the same variety adjoining which are at present quite healthy, and no Plum trees anywhere near. I notice, too, that more Plum trees are attacked this year than is common. The variety Victoria, as is generally known, is the one that suffers the most from this disease. In one large fruit garden not far away it is no uncommon thing for the proprietor to be compelled to replant as many as 200 trees of Victoria alone in one season owing to silver-leaf disease. This is a serious matter. In a cottager's garden near here I note a large tree of Plum Belle de Louvain, which bore a huge crop last year, is this year showing signs of silver-leaf disease. Has the weight of fruit borne on the trees, followed by a wet autumn in which maturation cannot be so perfect, anything to do with the progress and increase of the disease? In connection with the disease of the two Apple trees alluded to previously, I have treated one of the trees with sulphate of iron in the hope of arresting the disease, and also ridding the trees entirely of it. We are continually being told that there is no cure for silver-leaf; only dig up and burn the trees! From the appearance of the Apple tree thus treated I am in hopes of saving it, and if this is an assured fact, why should not the same happen to Plum trees so affected? I herewith send portions of the two trees, one showing the effect of treatment as compared with the untreated tree.—E. MOLYNEUX, *Swanmore Park, Hants.* [The point raised by our correspondent is a most interesting one. The Apple shoots from the treated tree are robust and only show slight traces of silver-leaf, while those from the untreated tree are weak and badly infested.—E.P.]

Worms on Lawns. I was much interested in Mr. Engleheart's comments *re* worms in your issue of June 7. I am compelled to say that after a long and close acquaintance with the effect of worms on the soil generally, and on lawns especially, I was not a little dismayed to read the Editor's note at the foot. I presume the good influence of worms on cultivated soil is generally acknowledged; it certainly ought to be with reference to lawns, England, I believe, the world over is noted for her garden lawns, and obviously this applies more to lawns made anything from fifty to two hundred years ago than to those of the last ten years. I suggest that the discerning care which made these fine examples did not include methods for the destruction of the worms; also that the lawn men to whom we are indebted for them worked in consonance with their coadjutors, the worms, and not for their destruction. This, then, is what should be practised in those days where a fine lawn is desired, even for games. It was very gratifying to read in Mr. Engleheart's note that "it is probably an impossibility to really exterminate the worms on a grass plot of any size." Would that it were on the smallest! E. J. PLATT.

Blue-Flowered Hydrangeas. A query that crops up with uniform regularity is how to induce Hydrangeas to give blue flowers. Various suggestions as to the cause thereof have been made, it being usually attributed to the presence of iron in the soil. By watering with alum water, or by mixing iron in some shape or other with the potting compost, good results are sometimes obtained, but failures are by no means infrequent. There are, however, two preparations now on the market, bearing the "bluey" names of Azure and Cyanol, that can be relied upon to produce the desired blue tint. Azure is brought out by Messrs. William Cutbush and Son of Highgate, and their exhibit of blue Hydrangeas at the Chelsea Show stood out as an undoubted proof of its efficacy. At the same time Messrs. Cutbush said that some varieties acquire this blue tint in a more pronounced manner than others. Naturally, it is of a bright rose colour, but readily changes to blue. The second to mention, Cyanol, is, I believe, a Continental preparation, but which can be obtained from some of the horticultural sundriesmen. The users of this preparation are reminded that water and soil must be free from chalk, that rain-water is preferable, and that no artificial manure must be applied.—H. P.

THE ROSE GARDEN.

SEASONABLE NOTES ON ROSES.

AS I write we have been experiencing another spell of weather that is quite unsuitable to Roses. The warmer showers of a few days previous were very useful in cleansing young growths from the very serious attack of insect toes which came on during the prevalence of east and north-easterly winds; but now (June 10) it is quite cold, and the growths are being battered and bruised by a hail gale from the south-west. On the mornings of the 8th and 9th inst. we had quite sharp white frosts here (East Sussex)—and not a few of the more tender varieties already show the effects of these, so that, taken altogether, our prospects are not so rosy as a short time back. The sudden and extreme changes have had a disastrous effect upon many wall Roses here (Uckfield) that were rapidly coming into full flower and were promising. During the spell of heat in the first week of the month great help was afforded our wall Roses by the free use of the syringe and water minus any insecticide,

is drawn up to the stocks, similar to the cutting up of Potatoes, we shall find the bark in a desirable condition when the earth is removed just previous to inserting the bud. Upon standard Briars also the number of shoulder shoots should be limited to two or three, leaving these at the most desirable height. If these breaks can be left at a triangle, or almost opposite one another in the case of only two, a much better head of Rose growth is likely to be secured. The full operation of budding may occupy some later notes at a more seasonable time; but I may say that any interference with growth at the time of budding is apt to check the flow of sap and so hinder a quick junction. A. P.

A GOOD CRIMSON ROSE.

DURING the present season I have had some remarkably fine blooms of Commander Jules Gravereaux, a Rose that has escaped the notice of a good many readers, for I do not remember seeing it mentioned. Its fine glowing scarlet-crimson blooms make a splendid show, and, unlike many of the Hybrid Perpetual Roses, its growth is nicely spreading. The flowers are rather semi-double; certainly

A BEAUTIFUL NEW MOCK ORANGE, PHILADELPHUS NORMA. (About one-half natural size. See page 328.)

This was applied late in the afternoon when the sun had lost its burning power, and again a little before sunset. Where this slight trouble was taken, the difference was remarkable, and I can recommend it during spells of warm weather. It acts as a cleanser, and is also a grand preventive of severe attacks of black thrip and red spider, so injurious to Roses when upon an extra dry wall.

The winds must have played havoc with maiden Roses not properly secured, more especially those upon standards. Early measures in this direction give us a number of sticks that are very useful, even before the young growths are sufficiently long to be tied the second time. Our own were earthed up early, and the varieties more susceptible to breaking out struck first. Some few Roses seem to break out at the very least pressure, while others, making a better union with the stock from the first, will resist quite a strong wind if earthed up and headed.

Next month should find us busy with budding, and a little preparation of the stocks is advisable. For example, it will be found a great help in lifting the bark of dwarf stocks if that portion of the stem is moist and soft. If some of the surrounding soil

they are not at all full, and the huge petals are curiously indented at the edges, which remind one of a big almost single Paony. This Rose would make a fine bedder, as every shoot will bloom. It will throw up very rigid growths about three feet in height, and these are crowned with flower-buds. The fragrance is very sweet, just of the old Rose scent we admire so much. It is rather strange that this is so, seeing that the Rose was raised from Frau Karl Druschki crossed with Cramoisie Supérieure, both scentless kinds; but the writer has a seedling of Frau Karl Druschki deliciously sweet. In this case a fragrant Hybrid Tea was employed as pollen parent.

I am certain we shall soon have quite a number of Frau Karl Druschki seedlings, and if they are as beautiful as Commander Jules Gravereaux and Nathalie Bottner, the so-called yellow Frau Karl Druschki, they will be most welcome. I had this latter growing close by the new Alexander Hill Gray, and some visitors thought Nathalie Bottner the more beautiful of the two, as the flowers were produced on erect growths and were of beautiful shape and fullness, reminding one somewhat of a very fine Mme. Hoste. DANFROFT.

FORTHCOMING EVENTS.

July 1. Royal Horticultural Society's Summer Show at Holland House (three days). Rose Shows at Sutton and Epsom. Scottish Horticultural Association's Meeting. Royal Agricultural Society of England Show at Bristol (five days).

July 2.—Hanley Floral Fête (two days). Flower Shows at Penarth, King's Lynn, Gosport, Alverstoke and Colchester.

July 3.—Flower Show at Ipswich.

July 4.—National Rose Society's Show at Regent's Park.

July 5.—Flower Show at Thornton Heath. Société Française d'Horticulture de Londres Meeting.

CULTURAL HINTS ON NEW AND RARE PLANTS.

(Continued from page 288.)

HARDY PLANTS.

Primula littoniana.—Perhaps of all the marvels of the modern Primula world this is the greatest—unique in design and in effect. Much of the latter is due to the glowing red colour of the bracts and calyces, in contrast with the purplish colour of the flowers. The latter are closely arranged in cylindrical spikes of 2 feet high, and from the earliest days of their expanding are in sharp contrast with the rich red of the tips of the spikes.

A ROCK GARDEN OF OLD-WORLD FLOWERS (See page 326.)

This remarkable plant, from the mountains of Western China, revels in rich, moist loam and partial shade. Easily raised from seeds. Sow when ripe.

Saxifraga Borisii.—Among the more recent introductions, this handsome yellow-flowered hybrid—said to have originated from the crossing of *S. marginata* with *S. Ferdinandi-Coburgi*—is full of promise. The habit of growth and fine vigour are strongly reminiscent of *S. marginata*, the glistening yellow flowers on 3-inch-high peduncles (stems) much larger than in either parent. The peduncles are usually three to five flowered. The plant delights in chalky loam and comparatively dry, rather sheltered places in the rock garden. Increase by careful division immediately after flowering.

Saxifraga decipiens bathoniensis.—One of the best, perhaps the best, of the red Mossy Saxifrages. There are some who have a strong liking for *S. Cibranni*, though the flowers of the first named are larger. In cool places not far removed from thin shade, the crimson-red colour is longer retained. Increase by division after flowering. Seedlings come up quite freely around the established plants. All these red-flowered sorts make capital plants for edgings.

Primula cockburniana. The glorious orange-scarlet of the flowers of this plant is unique, and in

a plant of greater freedom of flowering and finer stature would probably have become the most popular of its race. As it is, it is indispensable for its colour. It is of easy culture in moist peat and loam, and seeds abundantly. Seedlings should be raised freely, therefore, and planted in sheltered groups in the rock garden.

TREES AND SHRUBS.

Salix magnifica.—This is perhaps the most remarkable of all Willows, for it bears handsome oval leaves up to 8 inches in length and 4 inches across, the male catkins being over six inches long and the female catkins nearly a foot in length. A native of China, it has recently been introduced

golden flowers, which sometimes exceed four inches in length. It is adapted for planting against a trellis or summer-house, but appears to be more suitable for a moderately damp climate than for a dry situation. Like other Honeysuckles, it requires good loamy soil and may be increased by means of cuttings.

Philadelphus purpureo-maculatus.—About half-a-dozen years have elapsed since this plant, which is of hybrid origin, made its appearance. It belongs to the dwarf-growing group of the family, of which the most familiar example is *P. Lemoinei*. *Purpureo-maculatus* differs from other kinds by reason of its white, fragrant flowers having a conspicuous purple blotch at the base of each petal. It must be given good loamy soil, and after the flowers have faded all the old flowering wood should be cut away, leaving as many vigorous young shoots as possible. Cuttings of young shoots root well in July.

Hydrangea Sargentii created considerable curiosity at the recent Chelsea Show, and an illustration of the plant appeared in the Exhibition Number of THE GARDEN. Its chief attraction is centred in its large and decorative leaves, which are sometimes a foot long and 8 inches or more wide. The flowers are in large heads, a considerable number of small, fertile blossoms being accompanied by a few large, sterile blooms. From what can be ascertained as to its requirements up to the present, it appears more suitable for the South-Western Counties than for general cultivation.

THE FLOWER GARDEN.

PRIMULA COCKBURNIANA AND ITS HYBRIDS.

THERE has been an interesting discussion in THE GARDEN as to whether this good Primula is biennial or perennial; but with a plant that seeds so freely as *P. cockburniana* I think this point is not so important as some would have us believe.

The most important point, however, is the part it has played and will play in the production of highly-coloured hybrids, and it would be useful to many readers of THE GARDEN if others would kindly write and say what they have attempted and the results obtained. It crosses freely with *P. pulverulenta*, which gave *P. Unique* and *Lissadell Hybrid*, the former, according to the laws of nomenclature, being the proper name. Now we have another fine acquisition in *P. Excelsior* (*P. Unique* × *P. cockburniana*), which is three parts of the latter and one part of *P. pulverulenta*, although from the Mendelian standpoint this may not be strictly correct. It is a brilliant crimson-scarlet, a perennial and hardy, and when shown before the Royal Horticultural Society on June 3 last received a unanimous award of merit. *P. Excelsior* was raised by Mr. T. W. Briscoe at Messrs. Veitch's Langley Nursery, and for further proof regarding its perennial character it may be added that all the stock has been worked up from a single specimen. The flowers are thrum-eyed, and are produced in tiers or whorls as in *P. pulverulenta*. Those on the examples shown averaged between four and six. So far as colour is concerned, *P. Excelsior* occupies a high position among hardy Primulas, and will, no doubt, be eagerly sought for by hardy plantsmen.

to this country *via* the Arnold Arboretum. Like other Willows, it thrives in moist ground, but it is probable that it will require to be grown in cultivated ground if the best results are to be obtained.

Styrax Wilsonii is a worthy addition to a genus containing a number of choice species. Forming a slender-branched bush, it bears drooping white flowers from the leaf-axils during June. Like the other species, it thrives in well-drained, loamy soil, but appreciates a little peat about the roots at planting-time. A moderately open position is desirable. Propagation may be effected by seeds or layers.

Fothergilla major, a decorative shrub allied to the Hamamelis, was introduced from America about a dozen years ago. Of fairly vigorous, upright growth, it bears large, oval leaves, which turn yellow previous to falling, and conspicuous, upright inflorescences of white flowers. The flowering-time is May. The best rooting medium is light loam moderately free from lime, into which a little peat has been dug. Moist ground and a little shade are preferable to a dry and sunny position. Cuttings of half-ripe wood root readily if inserted in sandy soil in a close case during July.

Lonicera tragophylla is a climbing Honeysuckle from China, remarkable for its long, tubular,

A USEFUL AND HARDY PINK.

THERE are many amateurs who are unable to grow the Carnation and Pinner. But Pinks, especially the white Mrs. Sinkins, readily adapt themselves to almost any position in the ordinary garden. There are other kinds in cultivation, but the one quoted is probably the best for general purposes. It is white and delightfully fragrant. Pinks are occasionally employed as an edging to the flower border, where they look very effective, and a few clumps dotted here and there among other plants are also appreciated, while for cutting purposes they have few equals. Soon after the plants pass the flowering stage propagation may commence if it is desired to increase the stock, and even where this is not necessary it is advisable to work up a few young plants at intervals of two or three years, because from these the finest flowers are procured.

Propagation is effected by pipings, which are the growths at the base of the old flower-stems. These are slipped off, and may be inserted either in the open ground or in a garden frame or hand-light; but if the latter method is chosen, the lights must not be kept too close, or the plants will, no doubt, damp off. Before beginning operations the soil should be made fairly fine, when the pipings can be inserted with the finger, pressed firmly, and watered in with a fine-rosed water-pot. Choose, if possible, a dull, cloudy day, and if not placed in their permanent quarters, select a shady part of the garden. If kept moist for a few weeks, they will soon emit roots, and may be transplanted to any position in October. S.

THE FRUIT GARDEN.

SEASONABLE NOTES ON FRUIT.

Strawberry Propagation. Those who desire to produce the finest crop of Strawberries, irrespective of whether the plants are to be fruited in pots or in the open garden, make it a rule to commence propagation early. And they are wise in their generation. It is also excellent practice, though it cannot always be adopted, to secure runners from plants which have flowered but have not been permitted to carry their crops. The object of this is to ensure the finest possible runners at the earliest possible date. Generally, the first runner on a strig is the best, but sometimes the second one is superior, in which event it should be selected, but it is not desirable that more than one on a strig shall be taken, except under compulsion. When pegging down is done in the alleys, an abundance of refuse manure or sweet leaf-soil ought to be incorporated with the ordinary soil, as the young roots will cling to it and enable the plants to be moved with a ball when the crucial time comes. Preference should, however, be given to layering into plunged pots or squares of turf inserted grass side downwards, more particularly when the plants are wanted for culture in pots. It will be necessary, in any event, to apply water in dry weather, or satisfactory roots will not be formed.

Thinning.—The thinning of crops cannot be put in hand too early after it is once clearly seen which fruits are naturally taking the lead in swelling. Neglect of thinning spells small fruits, but it has the still more disastrous effect of prejudicing the crop in the succeeding season; in fact, when a tree is overcropped in the early stages, it is often thrown into that abnormal

condition which spells a crop in alternate years, whereas, when rational methods prevail, there is fruit in all seasons, provided that nothing, such as bad weather, over which the grower has no control, comes along.

Pinching Gooseberries and Currants.—When these valuable fruits are in excellent health, they produce an immense number of summer shoots, and it behoves the cultivator to reduce them with a free hand. They deprive the swelling crops of the light and air which they demand to enable them to put on perfect colour and develop the finest flavour, and they rob the buds at the base of the spurs of the same essentials to proper progress. The initial pinching is generally to about six leaves, but the exact number must, of course, be decided by the condition of affairs prevailing in each plant. Later, other growths will start, and these must, in their turn, be reduced; the accepted rule is to two buds. This treatment is wise with all forms of plants, but is imperative in the case of the popular codon.

Wall Trees.—In addition to the training which has to proceed in wall trees throughout the whole of the growing season, it is most important that the soil shall be maintained pleasantly moist at the roots. Immediately there comes complete dryness the plants lose their power to imbibe food,

doors as generally as they might be to advantage, but one has doubts upon the point when one sees the wretched specimens of many gardens. The Vines are never pruned, the bunches are never thinned and the plants are never watered, with the inevitable result that the crop is a miserable apology for what Grapes ought to be. At this stage it will be necessary to thoroughly moisten the soil, and if a shortage of food is suspected, add a heavy application of liquid manure. See that the laterals bearing bunches are stopped at one or two joints beyond the fruit, according to the space available for perfect leaf development.

GARDENS OF TO-DAY.

A NOTABLE RIVERSIDE GARDEN: TAPLOW COURT.

THOSE who seek pleasure in the neighbouring reaches of the Thames are familiar with the site of Taplow Court, the grounds of which extend a mile and a half along the river above Maidenhead. But few know anything of the intensely interesting associations of this historic spot. The situation is a prominent one, occupying a site on a spur of the Chiltern Hills which has been lived on

SOUTH FRONT OF TAPLOW COURT, SHOWING TUMULUS OR ANCIENT BURIAL PLACE.

and the progress of the crops is arrested automatically. Wall borders are never as moist as the soil in the open quarters of the garden, because some rain must be thrown off, while if the walls are of bricks, the trouble is accentuated, since the bricks themselves absorb much moisture from the ground. The keen grower is constantly on the watch, and when the soil approaches dryness he gives it a thorough soaking, and perhaps supplements it with weak liquid manure. An occasional heavy hosing also does an appreciable amount of good.

Outdoor Grapes.—There are many people who hold the opinion that Grapes are not grown out of

continuously from time immemorial. At the present time Taplow Court is the residence of Lord Desborough, who takes his name from the Hundred of Desborough, which includes most of his old constituency of South Bucks and also Marlow, which, Lord Desborough's great-grandfather, Pascoe Grenfell, represented in Parliament from 1802 to 1820. In the time of Alfred the Great, the county of Bucks was divided into Hundreds.

In an old churchyard on the south front of Taplow Court is a large, grass-covered mound or tumulus. This was the burial-place of a Viking, who probably came up the river and was killed in battle on the top of the hill. This tumulus, of which an

ROULIER'S WEIR AS SEEN FROM THE WELL-WOODED GROUNDS AT TAPLOW COURT.

illustration appears on the previous page, was opened in 1883, when a large number of gold and silver and glass vessels were found, together with the remains of the warrior's sword and spear, and these have been deposited in the British Museum. The tumulus, when opened, was found to consist largely of chipped flints, showing that the site had been occupied for some time by the people of the Flint Age. There are other tumuli in the woods above the river which have not been opened, notably the one under an old Oak tree which is reported to have been planted by Queen Elizabeth during her imprisonment at Taplow Court in the reign of her sister Mary; the tree is thought, however, to be of greater age. A pond near the house—now, by the way, aglow with Irises and Water Lilies—is known as Bapsey Pond, and is claimed to have been used as a pool for baptisms by Early Christians.

The Cedar Walk.—From an arboricultural point of view the outstanding feature is unquestionably seen in the stately and majestic Cedars that have been planted with a free hand in these extensive gardens. One veteran Cedar of Lebanon, obviously the oldest in the place, is considered to be one of the finest specimens in the country. The girth of this tree, taken on the occasion of our visit, was found to be 16 feet, measured 5 feet from the base. Its history is lost in obscurity, but from its appearance it is probably one of the oldest in the country. It is worth noting, however, that none of the original Cedars of Lebanon introduced to this country is still standing. This is the opinion of our best authorities, and while there is some doubt concerning the date of introduction, it was probably about the middle of the seventeenth century. A magnificent Cedar Walk is one of the features of the place. Within recent years this has been extended, and is now half a mile long. The continuation was started by trees planted by the late King Edward VII. and Queen Alexandra, and is finished by

give a fairly good account of themselves.

Among a number of shrubs from New Zealand presented by the late Right Hon. Richard Seddon were observed one or two fine specimens of *Pittosporum eugenioides*, which were perfectly happy in the garden outside, even though it is a subject usually relegated to the greenhouse.

The Flower Garden.—The formal garden near to the house is well designed with bold and effective beds. Tulips are extensively used for spring effect. Early and late varieties are planted alternately, and these, with a groundwork of pink and blue *Myosotis*, keep up a long display of bloom. Standard varieties of Tulips such as Clara Butt, Pink Beauty, Inglescombe Yellow, Pride of Haarlem and White Swan, are much in favour. At the present time the

trees planted by His Majesty King George V and Queen Mary. Among other notable personages who have likewise planted trees in the Cedar

Walk are the Duke and Duchess of Connaught, the Duchess of Saxe-Coburg, Princess Mary of Wales, the Duke of Portland, Prince Arthur of Connaught, Princess Patricia of Connaught, the Crown Prince and Crown Princess of Sweden, Prince Christopher of Greece, Prince George of Greece, Prince Fushimi of Japan, Lord Desborough, Lord Addington, the Hon. Monica Grenfell, the Right Hon. I. I. Halsey, Pro. Grand Master of England; Sir Arthur Godley, K.C.B.; the Right Hon. H. H. Asquith, M.P.; the Right Hon. A. J. Balfour, M.P.; Earl Grey, Viscount Milner, the Right Hon. J. B. Haldane, M.P.; the Right Hon. Alfred Lyttelton, M.P.; and the Right Hon. J. Chamberlain, M.P.

A great variety of trees, including Oak, Elm, Ash, Beech, Sycamore, Poplar, Box and Yew, flourish in the grounds, which, by the by, are situated over chalk. The Spurge Laurel or *Daphne Laureola* grows freely under the shade of trees, while even *Rhododendrons*, which usually do not grow well over a chalky soil,

beds are brilliant with *Pelargoniums* Henry Jacoby, edged with *Flower of Spring*

Among the much-prized garden ornaments are three stone urns, presented by Queen Anne to the Earl of Orkney, then proprietor of Taplow Court, who commanded the right wing at the Battle of Blenheim. Two recent additions to the garden take the form of handsome Italian gates and a fountain with mosaic basin, both of which were presented to Lord and Lady Desborough on the occasion of their silver wedding.

Herbaceous borders and the Rose garden are much admired, and add to the beauty of this delightful garden. The rock garden—unlike some of the modern examples, where rocks and labels form the most prominent features—is freely planted with old-world flowers, forming a happy blending of a wild garden with that of a rock garden. The two illustrations pages 324 and 327 of this phase of gardening give a fair idea of the charming effects now to be seen. The tall spikes of Foxgloves stand out in the background from a wealth of greenery of hardy Ferns. Clumps of Irises here and there are interspersed with London Pride, while *Crydalis*, *Periwinkle* and *Arabis* each does its work in clothing large stones and rocks. The rest is filled in with large patches of *Cerastium* and such easily-grown subjects as *Thrift*, *Iberis*, *Rockfoils*, *Stonecrops* and dwarf *Campanulas*.

We cannot bring these notes to a close without paying tribute to Lord Desborough, who is the type of Englishman that every Britisher admires. His whole-hearted interest in manly sports, such as

THE FAMOUS CEDAR WALK, TAPLOW COURT, WHICH IS HALF A MILE LONG.

swimming, rowing, boating, boxing, &c., in each of which he has achieved great success, needs no further comment here. As Chairman of the Thames Conservancy it is fitting that the riverside residence of Taplow Court should be in the possession of one who cherishes its associations in so high a degree.

THE GREENHOUSE.

CANNAS IN THE GREENHOUSE AND FLOWER GARDEN.

IN the nurseryman's catalogues of twenty-five to thirty years ago the only *Canna* that was recommended for the sake of its flowers was *Canna indiflora*, the others being regarded solely as ornamental foliage plants. Now, however, all this is changed, and both for the decoration of the greenhouse and the embellishment of the outdoor garden *Cannas* occupy a prominent position. This is not to be wondered at, as the flowers of many of them are really gorgeous, and a succession is kept up for a long time, added to which the leafage is very handsome. For the present-day race of *Cannas* we are, in the first place, indebted to M. Crozy, then of Lyons, who devoted a great deal of time and attention to their improvement. The result of this was first manifest in the year 1888, when some half-a-dozen varieties were given first-class certificates by the Royal Horticultural Society, that honour being easier to gain then than it is now. From their showy character these *Cannas* made quite a *furor*, and for trade purposes they were propagated as rapidly as possible. What is more, the raising of new varieties was taken up by others, so that each year saw additions thereto. Striking, from their novelty, as were those of 1888, they are now quite out of the running, the more recent varieties being in all respects superior to the early ones.

For the embellishment of the greenhouse these *Cannas* may be grown in different ways. In the first place, good flowering examples may be grown in 6-inch pots, and, if liberally fed, they will yield a wealth of blossoms. Larger examples can, of course, be readily obtained, either by increasing the size of the pot or by growing them in tubs. In this way they are very useful for the decoration of the conservatory, or for standing out during the summer on balconies, terraces and similar positions. Besides this, they are of great service for bedding out during the summer months, that is, if their somewhat hungry nature is taken into account. This fact was forcibly brought home to me during the hot, dry summer of two years ago. Having occasion to visit two different gardens, I found in one some beds of *Cannas* which should have been very fine, but were simply struggling for existence. The beds in which they were growing had the soil heaped up above the surrounding ground, as is so often seen, the result being that it was quite impossible to keep the roots supplied with an adequate amount of moisture. In the other

the beds were finished off somewhat sooner fashion, so as to conserve all the moisture, and the condition of the plants was splendid.

When these *Cannas* are grown in pots, a desirable feature is that they can be safely wintered almost anywhere it kept free from frost. Another point is the readiness with which they can be increased, as for propagating purposes an established plant can be divided up into as many pieces as there are crowns or eyes; and, placed under conditions favourable to growth, each will form a flowering plant in a short space of time. *Cannas* need a fairly rich soil, such as two-thirds good loam to one-third well-decayed manure, while a sprinkling of sand will serve to keep all open. Good flowering examples may be purchased at this season at a comparatively cheap rate, but, owing to the expense of carriage, many prefer to note the best when in flower, and obtain them during the winter in a dormant state. At that time the rhizomes can be sent by post

ORCHID NOTES.

CYMBIDIUMS.

PROBABLELY no group of Orchids has attained such popularity during the last few years as the *Cymbidiums*, and this is undoubtedly caused by the reintroduction of that beautiful species *C. insignis* (syn. *Sanderi*). It was first discovered by M. G. Bronkard in 1900, who found it growing along ravines in Annam. Since then M. Mohlitz (Messrs. Sander's collector) has sent it home in quantity, and now there is scarcely a collection of renown that does not contain this fine plant. The flowers are white, tinged with rose pink, while the lip is handsomely marked with rosy crimson. It has proved a magnificent parent, and among the progeny already shown are *C. Pauwelsii* (insigne lowianum), *C. Alexandri*

EARLY SUMMER IN THE ROCK GARDEN AT TAPLOW COURT

As tastes differ so much, a selection is a difficult matter, but the following are all good: Alphonse Bouvier (rich crimson), A. Ortman (velvety purple), Baron de Richter (bright apricot, lighter edge to the petals), Black Prince (velvety maroon), Dr. Badingen (crimson scarlet), Duc Ernst (reddish scarlet), Elizabeth Hoss (yellow, small red dots), Evolution (yellow, pink centre), Frau E. Kracht (rosy salmon), Fürst Wolf (deep crimson), Gackwar of Baroda (yellow, large crimson spots), J. B. Van der Schoot (lemon yellow, purple spots), Jupiter (scarlet, edged yellow), King Humbert (bright reddish orange), Königin Charlotte (dwarf, scarlet, gold edge), Météore (orange scarlet), M. de Raynal (pink), Niagara (scarlet, broad yellow margin), Ottawa (rosy cerise), R. Wallace (canary yellow), Stuttgartia (scarlet and orange), William Saunders (rosy crimson) and William Watson (deep salmon).

(insigne eburneo-lowianum), *C. gottianum* (insigne eburneum) and the pretty *C. Doris* (insigne traceyanum). Others are in commerce, but still there is plenty of scope for new raisers. As amateurs' Orchids, *Cymbidiums* occupy a leading position, especially the easily-grown *C. lowianum*, also traceyanum, eburneo-lowianum, low-gnum, giganteum, eburneum and the pendent devonianum. *Cymbidiums* last a long time in full beauty, their graceful, arching sprays of large and attractive flowers always being admired, while as foliage plants they are not to be despised in the Orchid-house.

Cultural Details. An ideal temperature is one between 55° and 65° Fahr., the latter for the summer months when fire-heat is needed, while during the winter period the thermometer may fall 5° lower, and no harm will accrue, providing the atmosphere is on the dry side. The season for

reporting will soon be at hand for the majority of both species and hybrids, if such an operation is deemed necessary. Annual disturbance is not required, and as a general rule every third year will be sufficient; but it is best to give attention to a few plants each season, rather than repot the whole collection at one time. A suitable rooting medium consists of the best fibrous loam one-half, *Osmunda* fibre one-fourth, and partly-decayed Oak leaves one-fourth, with a free admixture of finely-crushed crocks or charcoal, well mixing the whole a week or so before it is required. The group of

Orchids under consideration are strong-rooting subjects, and top-dressing is of no avail. Healthy examples which have filled their receptacles with roots may be moved on intact, choosing a pot two sizes larger. A few potsherds should be placed in the bottom for drainage and the soil pressed moderately firm; but it ought to be just below the rim when the operation is finished, thus allowing ample space for watering, for at no time must they be permitted to become dry at the base. If any plants are in a bad condition, all the old soil and decayed roots should be removed, also a few of the back pseudo-bulbs where they are numerous, when in all probability a smaller pot will be needed. Careful watering and extra shade for a few weeks will then soon pull them round. A moist, buoyant atmosphere is essential during the period of growth, and shade from direct sunlight is advised, or the plants will present a somewhat yellow appearance. A light spray overhead with tepid water will be found beneficial on bright, hot days, which not only promotes luxuriant growth, but tends to keep insect pests in check, particularly if the under sides of the leaves are sprayed. Once a year the plants ought to be carefully sponged over with a weak solution of some reliable insecticide, and at any time if scale is noticed, a pointed stick being the best article for its removal, while some growers utilise an old tooth-brush for this purpose.

Raising Seedlings.—So much interest is now taken in raising Orchid seedlings that a few words on the subject may be welcome. *Cymbidium* seed may be sown on prepared pots (as illustrated in *THE GARDEN* for January 11, 1913) directly it is ripe, or around the base of an established plant, selecting one that does not need repotting, and free from moss and lichen growth. The chief factor towards success in this interesting, and one might say fascinating, work is that the pots or plants are never dry. Even if this should happen for a few hours the results will be disastrous, because the seed is not covered in any way. When the first tiny leaf is made, the seedlings may be pricked off on prepared pots and grown on in a temperature of 60° Fahr., keeping the plants sprayed over occasionally and free from thrip.

S. LINDLEY

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Carnation Thomas a Becket.—A very beautiful fancy border Carnation of excellent size and form.

Carnation Scarlet Gem.—Of good colour, and shapely withal. These were exhibited by Mr. C. Blick, Warren Nurseries, Hayes, Kent.

Trollius patulus Bees' variety.—The plant is 9 inches or a foot high, the green leafage marked after the manner of these plants. The flowers are rich golden, 2½ inches across, and most

amund. It is very pretty and effective, and in decoration, we have no doubt will be much sought after. Exhibited by Mr. R. C. Notcutt, Woodbridge.

Philadelphus Norma.—This we regard as the finest of the Mock Oranges to date, not merely in the size and purity of its flowers, but also in the way they are traced upon the branches. The flowers, which are single, really appear to occur in long racemes. From Sir Trevor Lawrence, Bart., Dorking (gardener, Mr. W. Bam). (See page 323.)

Pæonia Gismonda.—The colour is rosy pink and the flower fully double. It is, of course, one of the herbarious section. From Messrs. R. H. Bath, Limited, Wisbech.

Rose Paul's Lemon Pillar (Noisette).—The flowers are of large size and, as shown, of a creamy white, doubtless due to age. It appears to be a good and useful sort. From Messrs. Paul and Son, Cheshunt.

Saxifraga brunoniana.—The flowers of this pretty Himalayan species are yellow, the petals acutely pointed. It is, however, welcome for the rosy crimson colour of its numerous stolons, as these, when seen in sunlight, are brilliant indeed. It is a moisture-loving species, and, given thus, should be planted in full sun. From Messrs. William Fells and Son, Hitchin.

Spiræa sargentiana.—A bushy-habited plant with numerous white flowers in clusters. It is very free. From the Hon. Vicary Gibbs, Elstree, Herts.

Astilbe Britannia.—The flowers are bright rosy crimson, arranged in plumes nearly three feet high. From Mr. Proffithich.

Rose Mrs. George Norwood.—This is a pink-flowered sort of the Hybrid Perpetual class. The colour may be described as a pale Mrs. J. Laing, though the flowers are longer and more tapering. Exhibited by Mr. Elsha Hicks, Twyford.

Blandfordia Cunninghamii.—A genus of Labaceous plants, the members of which are rarely seen. The species now mentioned is a native of New South Wales, and has long been known to cultivators. The flowers are crimson red, the upper part yellow, drooping, and arranged freely in a scape of about three feet high. Probably a scarce plant in cultivation to-day. From Mr. A. Worsley, Islworth.

Gladiolus Queen of the Whites.—This is a rather good white variety, and the only one to which an award was granted. Exhibited by Mr. R. Hoogstraaten, Sassenheim.

NEW ORCHIDS.

Two charming novelties, both gaining awards of merit, were shown by Baron Bruno Schröder, viz. *Odontoglossum crispum*. The Baroness, a magnificent variety of perfect form with violet purple blotches, and *Cattleya gaskelliana* Fairy Queen, a fragrant and well-coloured variety. Messrs. Charlesworth and Co. were given an award of merit for a remarkable hybrid of brilliant colouring, *Oncidioida Bella* (*Oncidium marshallianum* s. *Cochlidoda neetzliana*).

The foregoing awards were given by the Royal Horticultural Society on June 17.

THE NEW TROLLIUS PATULUS BEES' VARIETY.
(About one-half natural size.)

attractive. The plant was well shown. From Bees, Limited, Liverpool.

Sweet Pea Frilled Pink.—The name is descriptive, both as to colour and form. It is an interesting novelty in the Sweet Pea world. From Messrs. Dobbie, Edinburgh.

Sweet Pea Edith Taylor.—The flowers of this are bright rose pink and of good size. Seen in the sunlight, it is a most brilliant flower. Shown by Mr. Thomas Stevenson, Adlestone, Surrey.

Statice Suworowii alba.—Just a good white variety—not pure white—of this well-known

GARDENING FOR BEGINNERS.

CHRYSANTHEMUMS. PRACTICAL HINTS ON WORK TO DO NOW.

THE earliest-rooted batch of plants will now be getting established in their flowering pots. Although the heavy work of potting and placing will be over, there will be daily attention needed, and, although of a light nature, it is of vast importance, and must never be neglected. For some time after the final potting is done the plants are usually kept in blocks—that is, in several rows abreast—but they must be more thinly disposed in good time before they get drawn up and weakened thereby.

About Top-Dressings. The time for these to be applied will depend upon the condition of the roots of the plants. Some cultivators keep strictly to a rule, and do not top-dress until after the buds are "taken." This is a mistake, as the plants may suffer in the meantime, and they should be strong when the buds form. Again, it is bad management to wait and then apply one heavy surface-dressing. Directly roots appear on the surface, put on a thin sprinkling of rich compost. Fig. 1 shows a plant on a tile. Ample space is left for top-dressings, and these must be applied in a series, putting on a thin layer each time, and watering always with a rosed watering-can. No. 2 shows the space for the top-dressings; No. 3, the roots from the old ball of soil entering the new compost. No. 4. So treated the plants are always making progress, and, of course, liquid manure and other stimulants may be given in addition as required.

The Break and Resultant Shoots.—No. 5 shows the young shoots growing after the first break; but some varieties give trouble in this matter, as I will explain. On the main stem, below the shoots selected to grow on, shoots will also grow, as denoted at Nos. 6, 6; all such must be pinched out, as shown at No. 7.

Tying and Staking.—The main stem will have been staked at an early stage, but the young shoots—following the break—Nos. 8, 9 and 10, will also need stakes, and when the varieties are tall-growing they must be fastened to the wire supports. Very dwarf varieties only require one strong central stake.

Premature Bud-Formation.—Instead of a free growth, buds form, as shown at No. 11. In a few days' time a new shoot will grow past these buds; but they in turn also bear buds when about two inches long. In such cases it is advisable to pinch off the top to a point denoted by the dark lines as shown at No. 12. Very often a free growth of shoots is obtained by this treatment, as shown in sketch No. 13.

Plants in Their Summer Quarters.—A few strong stakes driven into the ground, and wires fastened to them, as shown in sketch No. 14, will save the cultivator the loss of many valuable branches and buds if the plants are made fast to the wires in due course. The rows of wires should be from 3 feet to 5 feet apart, according to the height of the plants, and about eighteen inches asunder in the lines from pot to pot. Bush plants, especially those intended for specimens, must have more room still, and be set out as shown by the circles No. 15. If the pots are held firmly in

position, tall stakes will not be needed for the support of these plants.

CUTTING HEDGES IN SUMMER-TIME.

To some persons it may seem a very easy task to trim a growing hedge. The experienced fence-man knows exactly how to do the work so as to improve a bad hedge or keep a good one in first-rate condition. Much may be done at this season to remedy defects, such as hollow places at the top and openings near the bottom. If the fence be a long, straight one, the novice should fix a garden line to stakes and then cut the top shoots back to the fixed line. If this be done, there can be no great error in trimming so as to secure an even top surface. Passers-by are severe critics

hedge must be cut quite hard back to the stumps of last year's growth; then there will be no danger of the fence getting out of true form. Use sharp, well-oiled shears. Hedges of Laurel must be cut with a knife, removing one shoot at a time. To cut through leaves indiscriminately with a large pair of shears would quite spoil the appearance of a hedge of this kind. B.

POTTING THE CHIMNEY BELL-FLOWER.

CAMPANELLA PYRAMIDALIS is a splendid subject for growing in pots for the furnishing of cold green-houses and conservatories during the early part of the summer. One sometimes sees splendidly-grown specimens not only in the greenhouse of

THE METHOD OF TOP-DRESSING AND DISBUDDING CHRYSANTHEMUMS.

of hedge-trimmers, and cause should not be given for adverse criticism.

The base must be wider than the top, but not out of all proportion; the sides should slope evenly from a given point at the bottom to one at the top. A hedge 2 feet wide at its base should be about sixteen inches wide at the top, both sides tapering evenly upwards. One often sees hedges that have been unduly hollowed out at the bottom. Such never present a pleasing appearance, and they readily permit dogs and fowls to go through. In the case of fowls, they often scratch up the soil and do their toilet under the sheltering hedge, and quickly spoil the bank and the general appearance. Where there are big depressions in a hedge it is not advisable to leave the young shoots in that part too long. They must be cut back to about four inches, and at the next cutting left a couple of inches longer, and so on, until the low portion has filled in a solid form to the normal level of the hedge. The young shoots on a perfectly-formed

a keen amateur cultivator, but also in groups at shows—groups of miscellaneous plants arranged for effect. Much care is needed in order to grow good plants. If they are allowed to remain for a considerable time in boxes or seedling beds before being placed in flower-pots, great difficulty will be experienced in getting them into good condition for flowering. These plants, even in a very young state, produce long tap-roots and few of a fibrous nature, so that it is advisable to place them in the pots at as early a stage of growth as possible. Where convenient, use deep, narrow pots. Do not cut off any portion of the tap-root, but twist it round so that it may be potted whole. Use a medium heavy compost, made porous by the addition of sand, and then plunge the pots to their rims in ashes in a cold frame. Between the pots leave a space of 6 inches. Repot the plants directly they require more rooting space, using a similar compost with the addition of some well-rotted manure. Avon.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Routine Work.—For the next month or two mowing, edging and rolling of paths will be the principal items of work, and to keep things in good order, nothing must be allowed to get behind. Even mowing if left over for one week makes a double amount for the following week, so it is wise to skim the lawns over with a light machine even if there is not a heavy crop of grass.

Shrubs. Those planted early in the season, or even last autumn, must be periodically inspected, and, on the slightest sign of drought, copious waterings should be given. Specimen trees may even have to be sprayed overhead morning and evening to ensure them coming through a trying time of drought. Mulching also with short manure or leaf-mould is a distinct advantage in such cases, and may help to save the lives of many valuable shrubs or trees.

The Rose Garden.

Just now there is much to do in the Rose garden, as not only must the young shoots be kept free from fly by hosing overhead or spraying, but the plants must be kept well watered if a full measure of success is to be attained with them. Removal of the dead blooms must also be attended to, as nothing tends more to make the garden look untidy than numbers of dead and dying petals lying about.

Mildew.—Whenever this is noticed, a little dry sulphur should be sprinkled over the foliage early in the morning, and, when the sun gets up, the fumes will in all probability prevent it from spreading. Where the attack is more general, spraying with a fungicide must be resorted to, and this may have to be repeated weekly to keep it in check, but an endeavour must be made to keep it off the opening flowers as much as possible.

Plants Under Glass.

Caladiums that are well rooted may be helped a little with waterings of cow-manure; but these, being very soft-rooted subjects, must not be given strong doses of liquid or artificial fertilisers. Specimen plants in large pots should be carefully staked out, so as to give each leaf as much space as possible to develop, and where these plants are to be used in the winter garden or conservatory, they must be mired to rather more air than is usual under the ordinary growing conditions of the plant stove.

Achimenes are growing freely and should now be staked, using a very small twig to each growth. Keep the plants in such a position that they do not become attenuated, though a little shade is quite necessary for their well-being. As they commence to bloom give them bi-weekly waterings with liquid manure, with a little Clay's Fertilizer occasionally as an extra stimulant.

Cyclamen nicely established in 3-inch or 4-inch pots should be potted on into their flowering pots at once, a fairly rich, porous compost suiting them best. From now onwards a frame with a cool ash bottom will suit them well, frequently spraying the plants to keep insect pests in check. A little shade on the glass during bright weather is also essential.

Medeola asparagoides also should be potted on and placed in positions where the plants may be trained up cotton or strings. A stove is not at all necessary for the cultivation of this useful plant, as more hard and useful sprays are obtained from an intermediate or cool house. A further batch of seedlings may be raised, and these, if kept growing through the winter, will provide really good material for early spring decoration, a time when it is very much in demand.

The Kitchen Garden.

Asparagus.—Now that there are plenty of other vegetables to be had, the Asparagus-bed should be left severely alone, allowing all the growths that are made from now to mature, thus building up good crowns for next season. On light soils a mulching of short manure, well watered in, will help the growth considerably, or a dressing or two of an approved fertiliser may be given. Where a mulching is not given, keep the beds clear of weeds by carefully hoeing or hand weeding, as weeds allowed to go to seed prove a pest for years to come.

Brassicas.—Continue to plant Brassicas as they become fit or as the ground becomes vacant, choosing, if possible, a showery time for the purpose, late-sown plants often proving more serviceable than those put in very early.

Coleworts.—A further sowing of this useful vegetable should be made, and Christmas Drumhead, a very hardy little Cabbage, sown at this date is exceptionally useful for cutting during the early winter months.

Fruits Under Glass.

Inside Vine Borders need plenty of water at this season, and Vines still swelling their fruit may be carefully fed, though it is not advisable to be too free with manure while they are in the swelling stage; but after this the late Vines will be ready for a couple of good dressings two or three weeks apart.

Outside Borders.—When these are relied upon for late Grapes, frequent waterings may be necessary, or, if experiencing a wet time, manure should be sprinkled on the surface for the rain to wash it in. Mulching is not really necessary, but where the border is very light or dry, a light mulching may be given, though I am inclined to think that the extra warmth in an unmulched border is conducive to better quality in the fruit.

The Hardy Fruit Garden.

Mulching Fruit Trees.—By this date the majority of fruit borders will have got pretty warm, and if dry weather ensues, it may be an advantage to mulch all the trees carrying a good crop of fruit, whether it be Apples, Pears, Plums, Peaches, or Apricots, giving a good watering immediately afterwards to settle the mulch down and to wash the manurial properties into the soil rather than let them be evaporated into the air.

Summer Pruning and Training.—Though I touched on this subject a week or two ago, it was rather early then for the majority of trees; but now the greater portion of the trained trees may be gone over, reducing the growth to 3 inches or 4 inches or, in some instances, even less. When the trees have not developed sufficiently to cover the whole of the space they are to occupy, the leading shoots should be tied in carefully, bearing in mind at all times what is required for the further development or furnishing of the trees.

THOMAS STEVENSON.

(Head-gardener to E. Mootata, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Staking Hollyhocks.—Stakes are a necessary evil, and should obtrude as little as possible. Although Hollyhocks require tall stakes, they, happily, unlike Dahlias, can do without them for a considerable time, but the want must now be supplied. Stout stakes about four and a-half inches high are what they want. Tie with binder twine, but do not fix a tie nearer the top of the plant than 2 feet, or strangulation will result.

Oriental Poppies.—These make a brave show during the month of June and the early part of July—too gaudy for some tastes; but in addition to the flaming red of the type, there are now several varieties having flowers in subdued art shades. It is late enough now to sow these; but if sown within the next week or ten days, they will make nice plants for planting next spring.

Carnations are now in bud, and will be grateful for a little stimulant to assist in swelling the buds. Soot, bow-manure, nitrate of soda—any of these will do it applied sparingly. If nitrate of soda is used, care should be taken that it does not come in contact with the foliage, which it will burn. Attend to tying or training, according to the type of stake used.

The Rose Garden.

Tying Climbers.—Climbing Roses are now making rapid growth, which should be regulated and tied in as growth advances. All superfluous main shoots should be cut away, so that those retained may get as much light and air as possible.

Cultivating the Soil.—Nothing contributes more to the welfare of Roses than to keep the soil regularly stirred.

Carpeting.—Opinions differ widely regarding the practice of carpeting Rose beds and borders. Where exhibition blooms are aimed at, carpeting is out of the question; but where Roses are grown for general decorative purposes, the system has much to commend it, especially where a bed is planted with a single variety and it is one possessed of considerable vigour. Violas are undoubtedly the best subjects for this work, and whites, pale mauves and pale yellows like Primrose Dame will, generally speaking, prove the most effective. Those who intend adopting the system should be thinking about stock for autumn propagation.

The Rock Garden.

Veronica saxatilis.—The bright blue flowers of this prostrate shrubby Veronica are very attractive, holding their own with the varieties of *Lithospermum prostratum*. It is by no means particular as to soil.

Potentillas.—Some of the dwarfier species make excellent subjects for the rock garden. Specially to be commended are *P. alba* (white, 6 inches), *P. nitida* (pale rose, 6 inches), *P. nivalis* (white, with silvery foliage, 6 inches) and *P. Thurberi* (reddish brown, 6 inches). None of the Cinquefoils require special treatment, except that they enjoy the sunshine.

Plants Under Glass.

Hydrangeas.—Autumn-struck plants with single trusses, if they have been forwarded in heat, will soon be getting past their best, and should have the flower-heads cut away. They should then be placed in an airy frame and receive some feeding to fit them either for producing a crop of bloom next season or for furnishing vigorous cuttings.

Streptosolen Jamesonii.—The deep orange flowers of this conservatory climber are very telling. Spring-struck plants should be fit for a shift into 5-inch pots. Sandy loam suits them, and if a little peat is added they will appreciate it. Shade only during very strong sunshine, and after August comes in gives them all the sunshine available.

Fruits Under Glass.

Guanas.—Some families are partial to this fruit, which is generally grown on the back wall of ainery. The fruits will now be swelling, and the plants should be assisted by occasional doses of liquid manure.

Tomatoes.—Plants ripening their fruits should get all the light possible, and while overwatering should be guarded against, the plants should never be allowed to get dry at the root, or cracked fruits will be the result. If seed-saving is intended, the first fruits on a plant are the most vigorous, and should be selected for the purpose. Choose fruits typical of the variety in hand, always avoiding corrugated fruits.

The Hardy Fruit Garden.

Taking Strawberry Runners.—This work may still be done, but no time should be lost if autumn planting is the object in view. Layering in pots as recommended for forcing purposes is the best plan, but very good results can be obtained by layering on small squares of freshly-cut turf laid grass side downwards.

Protecting Strawberries.—If not already done, nets must be put on forthwith. In buying nets it is well to remember that when diamond pattern nets are stretched their full width, they shrink by one-third of their nominal length, so that when a net 50 yards in length as per list is stretched to its full width, it will prove to be only 33 yards in length. As mice are sure to make their appearance, a few traps should be set in each break.

The Vegetable Garden.

Turnips.—Make another sowing of White Early Milan for autumn use and thin successional sowings. Remove plants running to seed, as they rob the ground in the effort of reproduction.

Spinach.—It is next to impossible to get a supply of Spinach in the height of summer, and those who planted a portion of a south border with New Zealand Spinach will now be reaping the benefit. It is perhaps not generally known that as a substitute for real Spinach the leaves of the Silver or Seakale Beet are superior to the so-called Spinach Beet.

Onions must continue to have some feeding material of a nitrogenous nature. The hoe should also be kept going among the crop, and hand weeding must be resorted to in the lines.

CHARLES COMFORT.

Bloomfield Gardens, Davidson's Mains, Midlothian.

SOME GOOD THINGS IN A SCOTTISH GARDEN.

I HAVE always contended that everyone ought to cultivate the very best strains of both flowers and vegetables, as the labour entailed is identical, while the results are altogether superior. With a poor strain of anything there is not the slightest satisfaction to be derived from first-rate culture, only disappointment, and eventually a disposition on the part of the grower not to take undue trouble. How different it is when we know that the plants we tend daily will, with proper attention, produce crops that we can be proud of, and for which we have had no extra labour or trouble. I am in the happy position of being able to carry out my ideas on this subject, my employers delighting in having the best procurable strains of everything. A few notes on some of the finer things we have obtained during the last dozen years may be of interest to others situated in a cold, late district such as we have here. I will take flowers first, and only mention a few of the outstanding kinds that invariably succeed here.

Myosotis.—At the present moment we have a very lovely bed of Barr's Alpine Blue Myosotis, which has been greatly admired. I am sure in saying that it is by far the finest Forget-me-not we have ever tried. It comes absolutely true, is a lovely deep blue colour, and the stems are nearly a foot long, which makes it admirable for cutting. It is very hardy, a most profuse bloomer, and is earlier by a week or ten days than Sutton's Perfection. It may still be sown in a box set in a greenhouse is used. A real gem.

Delphiniums.—These thrive remarkably well. The plants in a large bed on a west border are never less than 10 feet high, the spikes of large flowers being 5 feet long. Grown from Barr's seeds.

Polyanthuses.—We grow two very beautiful strains, both being very fine in their way. Storrie and Storrie's Superb Mixed are prominent, because of the large size and wonderfully varied and brilliant colouring of the flowers. This grand strain also retains the delightful perfume of the old English Cowslips. The Munstead strain of white and yellow shades is also very choice and showy, the blooms and trusses being large and fine. It is well to raise a batch each year of these fine strains, as there is a tendency to deteriorate after the plants have bloomed twice.

Aquilegias.—The Long-spurred forms are very beautiful and useful for table decoration. Dobbie's strain of this fine plant is the best I have yet come across. The colours are not only varied, but most delicate and pleasing. Seed should be sown annually, as these fine hybrid strains do not usually live long.

Nemesias.—To Messrs. Sutton we are indebted for the introduction of this, our finest dwarf annual plant. Sutton's strains of both the original large-flowered type and the dwarf hybrid kind, with smaller flowers, are still the finest we have yet seen, and annually give a gorgeous display. Personally, I much prefer the dwarf hybrid type, which Messrs. Sutton have of late years brought to great perfection. Few plants give a more delightful range of beautiful colours, while the free-growing and profuse-blooming qualities of the plants are above praise.

Antirrhinums.—This is another almost indispensable plant nowadays, and as the range of colours

now available in separate packets is very large, everyone's taste is catered for. Here we prefer the intermediate type, and grow quite a number of colours each year. The best are usually Barr's Queen of the North, Barr's Yellow, Sunset, Sutton's Deep Crimson and Sutton's Orange King. Antirrhinums seldom come entirely true from seed.

Pentstemons.—A wonderful improvement has taken place in these noble plants of late years. Colours are now much brighter and varied than formerly, and a grand display can be had by massing in colours, or by having large mixed beds or borders. Here we like the lovely pink Daydream, raised by Mr. Hay while at Hopetoun, and Preston Hall Seedling, which is larger and deeper in colour than Newbury Gem, from which, I think, it was a seedling. Myddelton Gem is also very fine, as are Lady Mary Hope and Lord Charles Hope. George Holmes and White Giant are grand, but I lost both through drought two years ago.

Giant Daisies.—Sutton's strain of these is superb, the blooms when well grown being as large as bouquet Asters. The flowers are borne on long, stiff stems, so for cut flowers they are admirable.

Sweet Peas.—These thrive exceedingly well. We grow about thirty good named sorts each year. Favourites are Edrom Beauty, Dobbie's Sumpfoot Crimson, Isobel Malcolm, John Ingman, Etta Dyke, The Marquis, Red Star, Lady Miller, Constance Oliver, W. P. Wright, Asta Ohn, Helen Lewis, Nubian, Othello, Apple Blossom Spencer, Vermilion Brilliant and Hercules.

Roses.—These are quite a speciality, our collection comprising at least 150 varieties. We annually add some of the newer introductions, but a good many of these have had to be dispensed with for various reasons. The chief favourites grown in quantity are General Macarthur, Mme. Ravary, M. Paul Lede, Mme. Melanie Soupert, Lady Ash-town, Hugh Dickson, Mrs. John Laing, Gustav Grunerwald, Liberty, Caroline Testout, Viscountess Folkestone, Lyons Rose and Mrs. David McKee.

Herbaceous and Alpine Plants.—Of these we cultivate a large number of kinds, but space forbids my going into the names of these. I may say, however, that both old favourites and up-to-date varieties are well represented.

Fruit.—This is not a fruit district in a general sense, but a few kinds do remarkably well. Of Apples, Warner's King and James Grieve are the best. Pear Louise Bonne of Jersey is the only one that does much good. Black and Red Currants are always very fine. Raspberry Superlative is always grand, both in size and quantity. Of Strawberries, Laxton's Leader is invariably the best, carrying a very heavy crop of large fruits.

Vegetables.—These thrive well, for the most part, on our rich, heavy soil. Of Peas we grow a very large quantity, the following varieties being always dependable: The Pilot, Early Bountiful, Senator (a grand Pea), Glory of Devon, Carter's Daisy, The Lincoln, Dreadnought, Superlative, Royal Salute (the best late Pea) and The Gladstone. Cauliflower is always good, Sutton's Magnum Bonum, Sutton's Favourite and Veitch's Autumn Giant being the best. Sutton's Favourite is the best Cauliflower I know. Brussels Sprouts are greatly in demand, Dickson's Newtownards Gem being by far the best. Of Cabbages, Sutton's Flower of Spring for autumn sowing and Sutton's Favourite for spring sowing are unsurpassed. Lettuces of first-rate quality are always appreciated, and after many trials I can find nothing to equal

Carter's Holborn Standard and New York Giant. The former for earliest sowing is superb, and stands a very long time before bolting. New York Giant is a grand summer Lettuce, for, notwithstanding its huge size, it has never the least sign of coarseness. Tomatoes are always in demand, and we endeavour to keep up supplies for as long a season as possible. Laird's Supreme is still the best here, but Freedom, an American variety, is also very fine. Other varieties we always grow and which succeed very well are Stirling Castle, Carter's Sunrise, Sutton's Earliest and Magnus. The last named is the finest flavoured of all Tomatoes and a large, handsome fruit. It is of American origin.

Indoor Flowers.—Sutton's Dwarf Hybrid Schizanthus is excellent, the colours being so beautiful and varied and the flowers of such a fine size. This strain is a most profuse bloomer. Cyclamen Sutton's Giant and Sutton's Prize are always magnificent. This year they flowered for five months. We treat these as biennials. *Primula obconica gigantea* (Barr's strain) is by far the finest I have seen anywhere. Plants that started to bloom in December are still at this date (June 3) wonderfully fresh and bright. Ware's double and single tuberous-rooted Begonias are grown in quantity and are always greatly admired. The double kinds from a packet of seed are truly superb. Space forbids mention of other plants grown under glass.

Preston House, Linlithgow.

C. BLAIR.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET PEAS DAMAGED (R. H. H.).—The specimens of Sweet Peas sent were too far gone to enable us even to guess what was the source of the trouble; but we should think that, in all probability, slugs are to blame, and we imagine careful search with a lantern after dark would be likely to reveal them. Potassium permanganate in strong solution is excellent against these pests.

PHLOX AND EELWORM (Carlisle).—The Phlox is badly attacked by the stem eelworm. When once a plant is attacked there is no cure, and no attacked plants should be used for propagation purposes. It would be better not to plant Phlox on the infested ground, nor to plant things liable to attack, such as bulbs and the like. The soil should have a dressing of sulphate of potash (at the rate of 1 cwt. to 2 cwt. to the acre) in the spring, or kainit (at the rate of 4 cwt. to 6 cwt. to the acre) in the autumn. Infested parts of plants should be removed and burnt.

LILIES DISEASED (E. J.).—We can only say of your Lilies that it is one of the worst examples of the Lily fungus we have seen. The only thing to do is to gather up and burn at once every vestige of it. Indeed, it would be better to dig up and burn the bulbs also, and give the garden a complete rest from Lilies in general for two or three years. The Tulips will not be suffering from this disease, but from another peculiar to its own tribe. In their case also collect and burn all evidence of the disease, and later, when you lift the bulbs for drying, dust them lightly with sulphur. In replanting, give them a fresh site and, if possible, fresh soil also.

IRIS AND NARCISSUS BULBS ATTACKED (E. E. C.).—The Iris bulbs are attacked by the bulb mite (*Rhizoglyphus echinopus*), and the Narcissus bulb by that pest and the small Narcissus fly in addition. Either the soil is badly infested with the former pest, or the bulbs were already attacked when they were planted.

LUPINES AND IRIS (Bromsgrove Reader).—Lupines are often attacked in the way you describe, and sometimes a sort of root-rot occurs that produces the trouble. In any case, the cause of the bud-dropping lies at the root of the plant. It may be drought or even insects attacking the plant there. The Iris pallida varieties are often ditatory in coming into flower. Give them another year. We presume they are in full sun, with the rhizomes on the surface.

VIOLET RUST (J. W.).—The fungus on the Viola is *Puccinia violae*, the Violet rust. This early, cup-like stage is followed by brown spore masses, and late in the autumn by black spores which carry the disease over the winter. The fungus very commonly attacks the wild Violet, but it does not attack other plants than those belonging to the genus Viola. If it is only in a small quantity, root it out and destroy it immediately. If there is much, begin with a fresh stock of plants in another place next year.

IS LABURNUM POISONOUS TO PLANTS? (W. W. W.).—So far as our observation goes, we have never noticed any more serious results from planting beneath Laburnum trees than from planting beneath any other kinds of trees. As a rule, plants of herbaceous character fail to do themselves justice when planted beneath trees, partly by reason of the tree roots impoverishing the soil, partly by drought, and partly by shade, some trees, of course, having a more serious effect than others upon the undergrowth. We imagine that it can only be a case for further experiments. Perhaps there is something wrong with the working of your soil.

ASTERS FAILING SUDDENLY (J. H.).—The sudden failing of the German Asters has been attributed to many different causes, white worms, eelworms and fungi, and no doubt all of them are responsible at different times for the trouble, but it is, in all probability, generally due to the attack of a species of *Fusarium*. This fungus rests in the soil, and attacks first the root, then the stem, the water-vessels of which it fills up so that no flow of water is possible, the leaves thus rapidly withering. There is another soil fungus, at times causing root-rot, responsible for the trouble, and in both cases the need for avoiding planting in places where the disease has previously been is one to be borne in mind. Probably thorough liming of the soil and the sterilisation by steam of the soil used for sowing the seed in would reduce the attack very considerably.

FATSIA JAPONICA (Headingley).—The name of the plant of which a leaf was enclosed is *Fatsia japonica*, often known as *Aralia Sieboldii*. It is sometimes, but quite erroneously, termed the Castor Oil Plant, the true Castor Oil Plant being a totally different subject. Your plant is but following its usual habit, that is, as the new growth develops, the mature leaves on the lower part of the stem drop off. You can, if you like, cut your plant back to within 9 inches or a foot of the pot, when it will in time break out again. If you just pinch the top off, you will still have the bare stem, as it will push out from the upper portion. There is yet another way in which your *Fatsia* may be dealt with, and that, provided you have a sheltered spot in the garden, will perhaps give you as much satisfaction as any. This is to plant it outside and obtain a young specimen for your window. In the neighbourhood of London, *Fatsia japonica* is a valuable evergreen shrub, and as hardy as the common Laurel. Even in your colder climate it should succeed if planted in a sheltered spot. Once established out of doors, it will push out shoots from the base and in time form an effective specimen. Young plants suitable for your window can be purchased at a comparatively cheap rate.

THE GREENHOUSE.

GESNERAS (Lyndhurst).—As your Gesneras are good, sturdy plants and only 2 inches or 3 inches high, we do not consider that there would be any harm in dividing them now and repotting singly into 4½-inch pots. Of course, it is most essential that the roots should be disturbed as little as possible, and the plants kept rather closer than usual and well shaded till the roots take possession of the new soil. Some Gesneras are much more vigorous than others, and need increased root room; but, generally speaking, 6-inch pots should be large enough to allow three plants to give of their best. The very strongest may, if you wish, be put into larger pots; but as you seem inclined to divide, we should not, as above stated, dissuade you from doing so. In the culture of Gesneras, as in many of their allies, it should be borne in mind that they are greatly benefited by a free use of vegetable matter in the compost, and this, if possible, should be in the form of good, well-decayed leaf-mould. A mixture of two parts loam to one part leaf-mould and a liberal sprinkling of silver sand is very suitable for this class of plants.

ROSE GARDEN.

RAMBLERS FOR BUDDING (J. B.).—The lateral shoots would do very well, and, if strong, would make no difference to the future growth of the budded plants, but we should prefer a nice, strong, young growth. There are better white rambles now than White Dorothy, for it is not pure white. Try Schneeball or Lady Blanche.

ROSES WITH GREEN CENTRES (Hobensburgh).—The hard, green centres are usually regarded as the effect of a sudden check to growth just when the buds are forming. No preventive measures, beyond planting where the bushes are screened from north and east winds, are known. It is impossible to name Roses from malformed specimens such as these.

ROSES FOR BIG BUSHES IN ABERDEENSHIRE (D. D. D.).—You would find the following excellent for your purpose: J. B. Clark, Hugh Dickson, Mrs. Stewart Clark, Zepherin Drouhin, Dr. O'Donnell Browne, Johanna Schuss, Reine Marie, Beurrette, M. Desir, Comrad, P. Meyer, Nova Zembla, Sarah Barnhardt, Chesnut Hybrid, Juliet, Climbing Lady Ashburn, Maharajah, Ulrich Bruner, Frau Karl Dorschki, Mrs. John Jaung, Paul Neyron and Boule de Neze. All these should be hardy with you.

FRUIT GARDEN.

SPOTS ON MELONS (Oroz).—There is no fungus present to account for the trouble with the Melons. Have they been knocked or damaged while young? The latter favour is probably due to imperfect ripening.

A PREVALENT DISEASE IN APPLES (J. C.).—The Apples seem to be affected with the brown rot fungus *Monilia* (or *Sclerotinia fructigena*). This disease is rather prevalent this season, and it would be well to spray with Bordeaux mixture, half the strength usually used for spraying Potatoes.

FLIES ON PEAR TREES (E. H. S.).—We do not think the insects sent, which are species of *Pesicoides*, are likely to do much, if any, damage to the trees. They feed on dead matter, and disliking light are apt to travel in cracks in the bark. It appears there is much Pear seal on your trees, and this is destroying the spurs. Cut out all dead and dying wood, and spray with Bordeaux mixture.

SIDE SHOOTS OF PLUM TREES (In Doubt).—Yes, in the case of trees growing in gardens where the space is more or less restricted, unless a shoot is required to fill up a gap in the tree, the side shoots should be pinched back. In the latter case they should be allowed to grow unrestricted during the summer, pruning them back to half their length at the winter pruning. If the standard trees are growing in an orchard where ample space is provided, summer pruning is not necessary.

MILDEW ON VINES (J. Brown and A. Lincolnshire Man).—On the first appearance of the white patches of mildew on the upper surface of the leaves, spray every part of the stem and leaves with a solution of 1oz. of potassium sulphide to three gallons of water. Repeat this frequently while the Vine is still affected. As a preventive it is desirable to spray before the mildew appears, especially if it has been prevalent during the previous year. To ensure the destruction of the liberating mycelium during the winter, when the Vine is resting, the trunk and branches should be thoroughly washed with a solution of 1lb. of sulphate of copper dissolved in twenty-five gallons of water.

NECTARINES SHRIVELLING (Anzians).—Please see next answer to "H. S. O." below re Peaches dropping. If we were you we would give the old trees another chance, especially as you have had them under your care for so short a time. Old trees, even very old ones, bear grand crops when well looked after, and the fruit is usually of better flavour and quality than from younger trees. We would partly lift the roots this autumn (not merely top-dressing), and then give them a new body of soil to root into. Let the trees start naturally next year without any forcing, and in preparing the soil for the border do not forget to apply some bone-meal, say, three parts to a good barrow-load of the compost, and a liberal sprinkling of lime.

PEACHES DROPPING (H. S. O.).—The cause generally of Peaches dropping when the size of hazel Nuts is imperfect fertilisation of the blossom. If you cut a fruit open you will find that the stone is diseased. Imperfect fertilisation may be brought about by many causes, as follows: The want of vigour and strength in the trees, and consequently in the flowers; and the scarcity of pollen in the latter; dull, cold weather, and a damp, close atmosphere while the trees are in bloom. The best way of preventing this in future is to add new turfy soil to the roots of the trees in autumn, to water the trees several times in the course of the winter and autumn, and to take special care that the trees have abundance of air when they are in bloom, both day and night, while the weather is favourable. The flowers should also be artificially fertilised on dry, warm days by the aid of a rabbit's tail, drawing it gently over the pollen on the stamens of the flowers and applying to the stigma or centre tiny column of the flower. This is a simple and small matter, but it needs care and diligence in carrying it out.

MILDEW ON VINES (W. B.).—It may be that the Vine border and the general system of culture of the Vine in the past is at fault, and therefore, in a measure, the cause of the attack of mildew. For, without good and proper soil for the roots to flourish in, and intelligent culture in the way of generous watering, careful ventilation and the provision of a healthy atmosphere for the Vines to grow in, they soon become a prey to this and other diseases by reason of the weak and poor growth they make. However, if this is so, the remedy cannot be applied in the case of the border until autumn, but the careful management of the Vine in other ways as suggested above should be seen to at once. The best thing you can do now is to apply the same remedy as you applied before. The sulphur should be applied to the hot-water pipes in the evening

of a damp, calm day, and repeated the second evening if the first application is not effective. Be careful to apply front air sparingly in cold weather, because cold draughts are often the cause of an attack of mildew. The Grapes on the Vine you speak of (as per sample sent) are evidently badly affected. We should cut the worst of them out, and give the others a better chance of setting and finishing off.

KITCHEN GARDEN.

SEAKALE (Miss B. C.).—You can do no good by transplanting your Seakale now. Leave it until the winter time, then dig it up, keep the stronger crowns for forcing, and cut up the rest of the fleshy roots into sections 4 inches to 5 inches long, taking care to keep the upper parts in the same direction for convenience of planting. Plant the root sections in good deep soil which has been well worked and afterwards made fairly firm. As a rule the pieces should be placed in rows 2 feet apart, and 1½ feet apart in the rows. One year should suffice to form crowns large enough for forcing. It is of no use, however, planting Seakale in poor soil, as it never develops satisfactorily.

MISCELLANEOUS.

SAMPLE OF SOIL (G. W. R.).—We found nothing amiss with the soil, and could see nothing of the black substance of which you speak. It is quite likely to be a jelly-like growth which dries up and practically disappears when dry; but perhaps you could send us a little of the substance itself.

FLIES FOR IDENTIFICATION (R. S. C.).—The flies sent are allied to *Merodon equestris*, but do not belong to that species. They are hover flies, called *Eristalis tenax* and *E. arborum*, and the larvae of the former are the well-known rat-tailed maggots that live in the filth at the bottom of the gutters, sewers and dirty ditches. *Merodon* varies greatly in colour, but is usually foxy brown and very hairy. The shrill notes caused by its flight and its darting habit make it readily distinguishable when on the wing.

DESTROYING THE MOLE CRICKET (G. T.).—Probably the best method of destroying mole crickets is to inject carbon bisulphide into the soil in which they live, at the rate of about half an ounce to the square yard. Phospho Nicotyl has been found useful for destroying these insects in Jersey and Guernsey. Traps in the form of tubes of earthenware or wood, baited with some substance the pest likes and allowing entrance but not exit, may be buried in the soil, many of the pests being trapped like that and destroyed by dropping them into a pail containing paraffin.

WASH FOR CONIFERS (F. R. D.).—A wash which has been found successful for the treatment of Spruce trees affected by the Pine-apple gall is made by mixing six pints of paraffin, 1½lb. of soft soap and thirty-six gallons of water together, and using it in the form of a spray. It is essential that the soft soap and paraffin should be thoroughly mixed, and to ensure this it is advisable to dissolve the soft soap in one gallon of boiling water. While this is warm, add the paraffin and keep the mixture well stirred until a creamy liquid is formed, pour into the remaining water, mix well, and use either through a self-mixing spraying-machine or a syringe. In the case of the latter, put a syringful back into the vessel now and then in order to keep the wash well agitated, so that there is no possibility of the paraffin separating from the soft soap. From the end of April to the end of June is the most efficacious period for the use of the wash, for it is at that time the insects are most active. It is a good plan to use the wash about once every ten or fourteen days on badly-affected trees.

NAMES OF PLANTS.—Rustic.—Rose Thalia. — A. E. T.—1, Comtesse F. Hamilton; 2, Comtesse de Breuille; 3, M. Desir. — C. F.—Commander Jules Gravereaux. — M. M. Roxby.—We believe the white is Bennett's Seedling, and the pink an old variety of *Rosa gallica* or one of the very old Damask Roses. — J. B., *Clapham Common*.—*Centranthus ruber alba*. — C. B. B.—*Sisyrinchium angustifolium*. — Mrs. H. E. S. U.—*Cynoglossum Wallichii*. — Mrs. F. H. Curtis.—*Escallonia punctata*. — Mrs. F. A. H.—White Poplar (*Populus albus*). — K. D., *Sealby*.—*Pittosporum tenuifolium*. — B. N., *Cheshire*.—*Abutilon vitifolium* (shrub), *Cynoglossum fureatum* (perennial). — G. C.—*Gilia macrantha*. — C. F.—1, *Lilium pyrenaicum*; 2, *Gesnera cardinalis*.

THE EDITOR'S TABLE.

Sweet Peas from Cambridgeshire.—Mr. H. W. Churchman, Sawston, Cambs, sends flowers of two seedling Sweet Peas. The variety Alfred Challs is a pale silvery grey flower with pale blue veinnings, while Connie Ellis Improved is a dark variety, the standard being bluish maroon and the wings almost purple. Mr. Churchman writes: "I am sending you just a few of my Sweet Peas as growing for seed on poor soil. The marbled one is Alfred Challs, the dark one Connie Ellis Improved. I think these two good ones. The dark one requires shading lightly during the hottest sun."

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Cutting Dead Blooms Off Roses. We would remind readers that all blooms as soon as they have faded, or most of the petals have dropped, should be cut off the bushes. We prefer to cut down close to the first plump wood-bud. This assists in the formation of new shoots, on which we rely for our autumn flowers. If the soil can be given a good soaking with water and subsequently mulched with some short manure, the bushes will be assisted materially.

Morello Cherries.—The fruit is borne on the previous season's wood much in the same way as the Peach, and, like it, a sufficient supply of the current year's shoots should be laid in for supplying the crop next season. Only as much of the young wood should be retained as can be thoroughly ripened without unduly shading the current crop and foliage borne on the old wood. Superfluous shoots should be cut away with a very sharp knife, or gumming may ensue.

Endowment for Education in Gardening.—The outgoing Master of the Gardeners' Company is proposing, as an additional proof of his great regard for the Guild and for the interests of gardening, to offer a substantial sum to the President of the Board of Agriculture as an endowment for the cause of technical education in gardening. Certain conditions will be attached, the chief of which will be that the name of the Worshipful Company of Gardeners should be for ever associated with the gift.

Early Forced Figs.—Fig trees are accommodating, in that they produce more than one crop in the course of the year. At this season early forced Figs are swelling their second crop, and due attention must be paid to watering and feeding. If in pots, they will need looking over two or three times a day, and those planted out will probably need a good soaking once a week. Very little fire-heat is necessary now, but damping should be curtailed somewhat towards the evening.

Gooseberry Branches Diseased.—At a recent meeting of the scientific committee of the Royal Horticultural Society several specimens of Gooseberry branches were shown. They had died suddenly after starting into growth. This trouble with Gooseberries is usually due to the attack of the fungus *Botryosphaeria ribesii*. It is best to remove and burn the affected branches as soon as they are discovered, not allowing them to remain until the autumn. The branches should be cut away close to their origin, as the fungus fruits near to the base of the affected shoots.

Roses in the City of London.—It was with considerable interest that we visited the first exhibition held by the newly-formed City of London Rose Society in the Cannon Street Hotel on the 26th ult. Knowing as we do the enthusiasm for Roses that exists among City workers, we expected to see a good show, but were not prepared for

the magnificent display that Mr. Prothero and his committee had got together. The blooms were in many cases superb, and they were there in their thousands, well staged and well arranged. The society, which thus creates friendly rivalry among City workers, deserves every encouragement. An abridged report of the show, which was opened by the Lord Mayor, who is president of the society, will be found on another page.

Staking Dahlias. If not already staked and tied Dahlias should be attended to at once. Those intended for exhibition should have the central growth pinched out, selecting four shoots from the resulting breaks, and tying each to a stake, sloping them in an outward direction so as to admit as much light and air as possible to the centre of the plants. At present only sufficient water need be given to prevent the plants from flagging, but when coming into flower they should not be stinted in this respect. Traps must be set for earwigs, looking over them daily so as to rid the plants of these pests as quickly as possible.

An Interesting Flowering Shrub.—*Sophora viciifolia* is a showy and interesting Chinese shrub which blossoms freely during the latter part of May or early June. In the open ground it grows quite 6 feet high, while against a wall that height is doubled. The dainty green leaves are made up of numerous tiny leaflets, and from the axils of the leaves the short racemes of white, violet-tinged flowers appear. It is perfectly hardy and thrives in loamy soil, single plants growing in the open assuming a diameter of 8 feet or more. Seeds are produced freely and form a certain means of increase, although cuttings may also be rooted. It is one of those plants which dislike root disturbance.

Help for Aged and Infirm Gardeners.—On another page we publish particulars of the annual festival dinner in connection with the Gardeners' Royal Benevolent Institution, and we give prominence to it here because of the excellent work that it has done and is still doing. This charity, which has been founded over seventy years, provides pensions for aged or infirm gardeners, or the widows of gardeners, and we know that it is run on the most economical lines and that every penny subscribed goes to the relief of those who through no fault of their own, have fallen on evil days. Our British gardeners are admirably the finest in the world and now that they are at the height of their summer beauty and we are enjoying the beautiful flowers and luscious fruits that they produce, we urgently appeal to our readers to spare a little thought and money to those who have helped, directly or indirectly, to make our gardens what they are. A sovereign to these poor old people is a little fortune—so much to them and so little to many of our readers. Who will help? The secretary is Mr. G. Ingram, 92, Victoria Street, Westminster, and all subscriptions should be sent to him. We shall be glad to learn that our appeal to readers has not been in vain.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Pruning Scotch Roses.—This is the best time to prune large, thickly-furnished bushes of these early and sweet Roses. The pruning consists in cutting out the oldest of the shoots, so that younger ones, which are the more floriferous, may have ample space during the rest of the season. Young plants may be left till autumn and then slightly pruned in a similar manner; but neither young nor old plants should be severely thinned, otherwise they will become straggly, and to enable them to regain their former stiffness a number of growths have to be cut back. By the way, how badly Banksia Roses have done! Where we had long trails by the dozen last year, this year there have not been a dozen blooms in all—
R. P. BROTHERTON.

Puya chilensis Flowering at Cambridge. This interesting plant of the Pineapple family, concerning which a note was published in these columns on March 1, page 102, when mention was made of it coming into bloom, is now flowering and bearing a huge spike about six feet high, with an inflorescence 2 feet 5 inches by 1 foot 2 inches wide, in the form of a dense, rhomboid panicle, with racemose branches, which are densely crowded with flowers of a pale greenish yellow. During the whole time, the spike has grown on an average 3 inches per week until it reached the above height, after which it commenced to open its flowers. The plant, as mentioned in a previous issue, is an exceptionally fine specimen, the complete plant now measuring 9 feet 7 inches in height and 8 feet 2 inches in width. The side-growths are developing into fine rosettes, and will soon form a huge mass, replacing the main crown, which will undoubtedly die when the flower is gone. It is a native of the Northern Provinces of Chili, where the stem is used for corks and bungs, and the hard hooks on the leaves are used by the Indians for fish-hooks, being well adapted for that purpose. An excellent life-size painting of this plant may be seen in the North Gallery in the Royal Gardens, Kew—
F. G. PRESTON.

Scent in Flowers.—May I gently enquire the whereabouts of your charming correspondent "Anne Amateur's" aspersion upon American gardening taste as set forth in these words in her vivacious and otherwise delightful contribution to your columns on scent in flowers, page 275, issue May 31: "The American craze for mere size and conspicuous colours"? Will "Anne Amateur" be kind enough to give chapter and verse for this accusation? It may be that when her words met my eye I was in an over-sensitive state of mind, for I recall the fact that at that very moment I was engaged in comparing the delicious odour of one of the commoner garden Pinks with that of *Dianthus hybridus* Dr. Miles. Unlike Lamb and the modern florist, I own to the possession of a nose—and an ear, too, "Anne Amateur"

may think!—LOUISA KING, *Orchard House, Uma, Michigan*

A Beautiful Floral Combination.—In the course of some changes in the garden last autumn, I had the idea to plant that exquisite Rose Jersey Beauty in association with Spanish Irises of a good strain which I had seen at Mr. Bull's at Ramsgate the previous June. The result is a really charming bed. The Rose, as many of your readers will know, is of pronounced rambling habit and of vigorous growth. The flowers are huge singles of a creamy hue. The Irises, spearing up between the shoots of the Roses, form some delicious blends of colour. Inasmuch as the site of this bed had

Ireland, who, alas! has, with many other good pioneers, now passed away. If any reader of this note can inform me where this rare plant is to be obtained, I shall be very grateful. I always impress on those to whom I give this double white the imperative necessity of cutting down close to the ground, say, 1½ inches, all the blooming stems when they cease to be decorative; this ensures a good growth of vigorous young shoots, which, when about two inches long, can be planted by digging up and separating the rootstock with them attached, and thereby a large increase effected. Another increase is also possible in planting a portion—the lower for choice—of these blooming stems when cut off; for I saw last week, in the excellent garden of a relative of mine, fine young plants in bloom which last summer were the cuttings I refer to.—J. HILL POE (Captain D.L.), *Riverston, Nenagh, Ireland.*

THIS FINE SPECIMEN OF PUYA CHILENSIS IS NOW FLOWERING IN THE CAMBRIDGE BOTANIC GARDENS.

been nothing but a rough chalk bank covered with coarse, tussocky turf, I may perhaps be pardoned when I say that I view the transformation with pride. I may add, for what it is worth, that the plan is not only very beautiful, but quite inexpensive.—W. P. W.

The Double Sweet Rockets.—To supplement the paragraph in THE GARDEN of June 21, page 309, I wish to draw attention to the fact that there are two different whites, one much more free than the other, and much more loose in the habit of the flowering stems. There is also a rich purple variety, which I once possessed, having got a small plant from a celebrated gardener in the North of

Irish, who, alas! has, with many other good pioneers, now passed away. There is, however, I find, one drawback to its successful culture, at least in my garden, and that is the sparrows are fonder of the leaves of that variety than of any other Pink or border Carnation. Whether this is the general experience I cannot say. Of course, by a judicious use of black thread these cheeky little birds may be kept off; but they first found out the tastiness of the leaves when I was confined indoors for a few days, and on going out in the garden the damage was at once apparent, when I immediately took steps to prevent it—H. P.

A GARDEN.

Not apture to me and mine

Raptures in my garden spring,
Where the robes of Summer shine,
Rich from her embroidering,
And her gentle movement frees
Fragrance to invest the breeze.

Not on human sense alone

From the garden flows delight;
Birds their gladness clearly own;
Chant the bees in buoyant flight;
Butterflies make of their dance
Pleasure's perfect utterance.

Yet in yielding thus, to these

Visitants of airy wing,
Bliss that thrills to ecstasies,
Joy that stirs to revelling,
Wins my garden all their glee
For an added charm to me.

JAMES CARTWRIGHT.

Pink Gloriosa.—I am entirely in agreement with the writer of the "Note of the Week" in the issue for June 21 regarding the beauty of this Pink. Unlike your correspondent "C. A. G.," I have, however, had no cause to complain of its hardness during the two winters it has been in my garden. It (the garden) is situated to the South-West of London, and faces South-east. The soil is of a stiff, adhesive nature, and, of course, cold during the winter; but, despite this, the Pink Gloriosa has done well. There is, however, I find, one drawback to its successful culture, at least in my garden, and that is the sparrows are fonder of the leaves of that variety than of any other Pink or border Carnation. Whether this is the general experience I cannot say. Of course, by a judicious use of black thread these cheeky little birds may be kept off; but they first found out the tastiness of the leaves when I was confined indoors for a few days, and on going out in the garden the damage was at once apparent, when I immediately took steps to prevent it—H. P.

THE FLOWER GARDEN.

THE LONG-SPURRED COLUMBINE AND ITS CULTIVATION.

AMONG the hardy border flowers which have engrossed the careful attention of several of our leading growers during the past few years, the *Aquilegia* takes a prominent place and is deservedly becoming popular, and, together with the *Antirrhinum*, will for many years to come reign as one of the queens of the hardy flower border. To those unacquainted with the vast progress made by the hybridisers during recent years in converting the old-fashioned Columbine, with its compact flowers of sombre colour and little variety, into the gorgeous varieties known as the Long-spurred *Aquilegia*, the magnificent collections of blossoms shown by several firms of repute at the recent spring shows came as a startling revelation. Some of the blossoms were regal in form and colour, and no praise can be too high for this elegant genus of plants.

They are all hardy perennials, and are most accommodating, growing equally well in the rockery as in the hardy flower border. As the result of careful selection and hybridising, the Long-spurred *Aquilegia*, or Columbine, has been raised to a very high level of perfection, and contains some charming colours in almost every conceivable variety. Some magnificent named sorts are on the market; but, except for a definite purpose, such as grouping for colour, it is not absolutely necessary to grow them for the ordinary border display. Plants raised from seed, which can be obtained from several leading firms who have specialised in this genus of plants, will supply the commoner need, besides adding interest to the grower who may be fortunate enough to raise a finer variety than yet exists. At any rate, the various and delicately-tinted flowers amply repay the necessary care required in raising them.

Cultivation.—Seed should be sown very thinly in fine sandy soil in a cool house or frame in spring, and when large enough the seedlings should be pricked off on to a prepared border of good soil containing a large percentage of sand. In the early autumn these plants can be transplanted to their permanent quarters; and this process is often the cause of the failure of some of the plants to weather the winter. One of the complaints against the Long-spurred *Aquilegia* is that it will not stand our winter. As above stated, the *Aquilegia* is a hardy perennial, and the prime causes of the loss of plants are lack of drainage and badly-prepared beds. The seedlings have had liberal treatment, bordering perhaps on the tender side, during the pleasant warmth of summer, and often they are transplanted into a sour, water-logged border and left to battle against the adverse conditions of an inclement winter. Little wonder that the majority of the plants succumb! Provide well dug and drained permanent quarters for your plants, transplant them from the bed without unduly injuring the root ball, give them the necessary care that they may be firmly established before the winter sets in, keep the surface soil friable and free from weeds, and your losses will be nil, or nearly so. In the following May and June the beds will repay this attention with abundant blossoms. After flowering, the plants should be pruned of their dead flower-stalks, the soil well hoed, and new growth will be made, as

the plants improve yearly and need not be lifted for many years.

One of the most magnificent displays of blossoms the writer has seen this spring was a border of *Aquilegas* five years old, which had received treatment as here described. *Aquilegas* grown in clumps are most effective, and can be used advantageously for colour effects with named varieties, and, given the right surroundings, are unsurpassed in elegance and beauty. Recently the writer saw an arrangement of *Aquilegas* which might well be adopted by lovers of these plants. Seen under the rays of a golden setting sun, the sight almost baffled description. Two varieties, *cærulea hybrida* and *superba*, were massed in opposite beds 20 feet by 6 feet and flanking a sunken lawn. The first-named variety is a graceful form, bearing large flowers, the centre clear yellow, with spurs and sepals blue. The latter—*superba*—is a specially good long-spurred variety, with centre petals bright yellow, and spurs and sepals bright orange red. Some 20 feet of grass, in the centre of which was a small, circular bed of *Viola White Purity*, separated two similar beds, also filled with *Aquilegas*, in the one *Skinneri*, scarlet, tipped with yellow, and in the other a long-spurred white one which the gardener had raised himself. The contrast between the brilliance of *superba* and the elegance of the white variety, also the vivid colouring of *Skinneri* and the alluring delicacy of the pale blue of *cærulea hybrida*, had to be seen to be fully appreciated. In the same garden were beds of seedlings just flowering, and some excellent forms were to be seen; six varieties stood out as quite distinct.

The rockery, though small, also emphasised the usefulness of the *Aquilegia* for rockwork, as some fine clumps, three years old, were carrying masses of beautiful blossoms, all, I was assured, the choicest of former years' seedlings. Truly, then, does the Long-spurred *Aquilegia* vie with the Snapdragon in growing popularity, and should be more generally grown on account of its usefulness in the rockery and the border, and also for the fact that the flowers will last in water several days when cut. S. W.

SWEET PEA NOTES.

The Trials.—It groups of trials of scores of varieties are of real value to the growers of the world, the benefits this year ought to be twice as valuable as they were last year, since the National Trials are growing on the strong soil at Burbage in Leicestershire, and the International Trials at Reading, where the soil is decidedly on the light side. If the varieties were duplicated, which, I am led to believe, is not the case, some curious differences in behaviour would be apparent, for there is no question that they vary widely with the ground and to some degree with the climate in which they are growing. In a season or two, perhaps, we shall see these two fancied rivals in association, with sweetness in the camp if not in the perfume of many of the modern flowers. There is only room for one authority on Sweet Peas in this country, and the court should be the National Sweet Pea Society now, as it has been for a dozen years or more, but it must proceed on the best and cleanest lines.

The Shows.—The nights have started in many parts of the country, and some splendid flowers have been staged; but the grants will not join issue for a further fortnight, when they will gather at Vincent Square and later at Carlisle. I am

Delphinium Queen Mary.—When in Messrs. Bunyard's nurseries at Maidstone recently, I was struck with a new perennial Larkspur named Queen Mary. It is a beautiful shade of peacock blue, with a clear, creamy eye. I admired particularly the even disposition of the flowers on the stem, the whole forming a splendid Hyacinth-like truss.—W. P.

Forget-me-not.—There is a note about this (page 311), but I do not understand what is meant by "common." The true species is *Myosotis palustris*. Here we have masses of *M. sylvatica* growing in grass, which are very pretty, and among them the white variety is not at all unusual.—R. P. BROTHERTON, *Prestonkirk, N.B.*

Forget-me-not and Lithospermum prostratum. *Myosotis sylvatica*, the common Forget-me-not, is, as one of your correspondents writes on page 311, issue June 21, very pretty in combination with Woodruff and other white flowers, but it is surpassed by the variety *dissitiflora*, which is dwarfier and has much larger flowers. This in a mild spring comes into bloom in March, and though liable to be blackened at that time by frost, as it was this year, it soon recovers and flowers again. It is still in bloom (June 22). The shelter of shrubs is a great help to *M. dissitiflora*. *Lithospermum prostratum* in its native home in the Lower Pyrenees, where it goes by the name of the Frontier Flower, is quite the equal of *Gentiana acaulis* in colour. The flowers there are larger than the annual blue *Lobelia*, and have the two advantages over the *Gentian* in continuing to open all day in cloud or sunshine and in blooming for several months instead of weeks. Unfortunately, it does not succeed well with me, though grown with peat moss, granite sand and leaf-mould, our natural soil—limestone—being poison to it.—J. H. THOMAS.

Express Rockery Planting.—As one who has been engaged during the past season in making rockeries, I was deeply interested in the illustration of Mr. Bilney's new rockery on page 313 of June 21 issue. Although it is not mentioned in the notes, I think I can safely say that the two most important factors in Mr. Bilney's success were thorough preparation of the soil and the planting of several specimens of each kind. In rockery-making it is a common mistake to pay a great deal of attention to, and spend most of the money available on, the stones, with the result that plants are skimped. I am often tempted to think, after seeing some specimens of rockwork, that the best way of going to work is to put in the plants before a single stone is laid. It sounds ridiculous, but at least it would prevent many such miserable, over-starved examples as we now see. From half-a-dozen to a dozen plants set in a colony soon spread out into a glorious clump.—W. P. W.

FORTHCOMING EVENTS.

July 8.—Flower Shows at Wolverhampton (three days), Royal Scottish Arboreal at Paisley (four days), and Baltic Rose and Sweet Pea Society at Merchants' Hall, E.C.

July 9.—Flower Shows at Saltaire, Bath (two days), Beckenham, Elstree, Dover and Formby. East Anglian Horticultural Club Meeting.

July 10.—Flower Shows at Newmarket, Malvern, Potter's Bar, Finchley, Snaith, Maidenhead and Aylesbury. West of Scotland Rosarians' Society at Helensburgh.

July 11.—Manchester Rose and Summer Show.

July 12.—Flower Shows at Wood Green, Trowbridge and Steeton.

wishful that some of the younger enthusiasts should step in to show the old stagers that the world is not wholly theirs; but the new-comers will have to gird up their loins and stage quality. Speaking of quality reminds me that it will not be out of place to urge the claims of the real Sweet Pea, and to suggest that the coarse monstruosities should go to the wall. Novices are warned that flowers cut twenty-four hours before they are required, and placed instantly in water in a cool cellar where the temperature is quite steady, will serve them better than those cut an hour or so before the crucial moment; and, further, that when they are packing, it is necessary that the blooms shall be perfectly dry.

Watering and Feeding.—

Although Sweet Peas are good trenchermen, it is not simply possible but exceedingly easy to over-feed them. As far as watering is concerned, no experienced grower will ever do it until he is obliged; but in the case of feeding there is a decided tendency towards over-generosity. Loosening of the surface soil and mulching are persisted in to reduce the necessity for the applications of water, and wisely so; but the same judgment and discretion ought to be given to the use of liquid manures. When special feeding goes so far that the plants become gross, the flowers are too widely separated on the stalk, and usually they become large at the expense of substance, with the result that they have a flabby aspect. Correct feeding is difficult. It is an art which cannot be too closely and too intelligently studied. It will be ascertained quickly that the treatment which suits one variety will not suit another, and that following identical rules in different soils and localities will by no means bring about identical results. In any event, it is necessary to adhere strictly to the rule never to apply liquid manure of any kind when the soil is dry, and also to consider the wisdom of affording as varied a diet as circumstances and conditions permit.

Staging Blooms.—The importance of arranging the colours carefully cannot be over-estimated. It is very clear from the exhibits which one sees at many shows that some cultivators take the view that fine blooms are all that is required. When the competition is poor, this principle may, and usually does, work out all right; but when the rivalry is keen, skilful arrangement tells another story. When the judging is done on what may be termed general impressions, the group in which the varieties are so disposed that each aids the other is bound to come out on the top; while, when pointing has to be done, marks will be given without hesitation to the artistically-arranged exhibit

which the carelessly-arranged set could never hope to secure. The tyro who does not clearly see the force of this ought to arrange and rearrange a few sets of twelve until he fully grasps how much the judicious association of colours adds to the effect of a set. It will be time well spent, and will mark the difference between success and failure, sooner or later.

H. J. W.

THE CARNATION: ITS HISTORY AND CULTIVATION.

Its History.—The fascination of the Carnation is very great, and so we find people year after year

nearly all plant history up to the middle of the sixteenth century veils that of the Carnation in an impenetrable gloom, and we do not know when it first found a place in English gardens. Continental authorities, on the other hand, can trace it back centuries earlier, and they have also to their credit cultural treatises long in advance of any of ours. Liebhaut, in the sixteenth century, shows that two distinct sections were cultivated in France. To Clusius we are indebted for the knowledge that a wonderful type of apricot-coloured Carnations was common in Silesia. Monographs appeared in France in the seven-

teenth century—"Le Jardinage des Cilletts" in 1647—which fully demonstrates the great hold the flower had on the florists of that country. Nothing of the kind appeared in England till a century and a-half later, and it is a remarkable fact that nearly all our writers—Gerard, Parkinson, Rea, Laurence, Maddock, Hogg—refer to the introduction of Continental types which were seized upon by English cultivators. We know that our present border Carnations are derived largely from a German strain imported by the late Mr. Martin Smith, the great value of his labours being the production of a stronger plant with considerably more vigour than the devitalised English type which it displaced.

Its Cultivation.—Would-be cultivators, in spite of all that has been said to the contrary, must recognise in the Carnation a difficult plant to manage. Treated as a hardy plant, which undoubtedly it is, it exhibits remarkable peculiarities. One year we find it thriving like the grass of the field, and the next dying by dozens, and producing insufficient stock to keep up a succession for the next. Varieties exhibit these failings more or less intensely, some not at all; and the only way many of us can maintain a healthy stock is to cultivate a portion under glass and propagate from that. Understand, it is not because the varieties are not hardy, for the plants from inside layers planted in

MINIATURE WATERFALLS IN THE ROCK GARDEN AT LEONARDSLEE.

attempting its cultivation with a success in the inverse ratio to their enthusiasm. Its very history fascinates the searcher after flower-lore of the past, and quite a serious accretion of fabulous material has gathered round its name. In this respect it may be called the King Arthur of the vegetable kingdom. Similarity of designation to other plants has been responsible for a good deal of controvertible assertion of this kind; but there is also a more regrettable readiness to give to it names of other plants as synonyms to which it has no right whatever. The obscurity which envelops

the autumn will be found to winter equally as well as, or better than, those from layers from the open, but they do not continue healthy if grown continuously in the open. Another way to maintain a healthy stock is to introduce layers from a different part of the country, and a warmer one if possible. There is abundant recompense for the labour involved in cultivating a portion of the plants under glass, in the fine blooms they produce long in advance of those from the same varieties out of doors. I have for some time been cutting beautiful blooms from border Carnations in 6-inch pots, but to have

extra strong plants it is to be preferred that two or three should be potted up in 7-inch and 8-inch pots. It is usual for these plants to yield a second crop of bloom from the strongest of the "grass"—the young shoots which grow from the base of each plant. Hence it is generally late before pot-grown plants can be layered, but to make up for that the layers root in less time than those on border-grown plants. Cuttings from the stems strike with facility in autumn in bottom-heat, and the plants from these flower a little later than the others. They display a different habit of growth, and, as I think, produce a better type of flower.

The Best Manure.—Apart from the tendency of some varieties to "wear out," as it is called, plants during the summer months not infrequently suffer from an insufficiency of nourishment. Carnations, it is true, dislike a highly-manured soil, but they have no dislike to manure provided it is presented in the form of a surface-dressing. Some folks give them a mulch, but a mulch in early summer is not enough, and repeated applications of soot, superphosphate or one of the special Carnation manures are in many soils essential to the health of the plants. Autumn planting is, as a rule, better than spring planting; but where it is incumbent that the latter must be the practice, then it should not be delayed till spring has given place to summer. Once into February and the soil in proper condition, Carnations succeed better planted then than if delayed till April or May.

Layering I have always found to be a much simpler operation than it is made to appear in books. In light soils layers root perfectly without the addition of anything to further the operation, and where it is considered important to apply a compost, it should be seen to that it is placed where the roots will get into it. For it is usual to see it placed above the part from which the roots proceed, and therefore of no use. When the shoots to be layered are too far up the stem to be brought to the soil-level, the plant should be loosened from its stakes and brought down so that the layers are close to the soil. To keep shoots from snapping off they should be twisted round, when none will be broken. On taking the rooted layer, cut the part which united it to the parent plant close to the stem of the layer, and roots will be produced from the cut portion. When an inch or 2 inches are left of the old stem, it is not only unsightly, but may damage the young plant. R. P. BROTHERSTON.

THE JAPANESE IRIS.

Now that *Iris lævigata* (syn *Kæmpferi*) is flowering so well in many gardens, it may not be out of place to draw attention to its peculiarities in regard to culture. It is an Iris that likes to be kept fairly dry in the winter and wet in the summer. In Japan it is extensively grown in the Rice fields, which are heavily manured in the winter when dry, while during the summer the fields are flooded by irrigation, when the Irises are about two inches under water.

OUR FIRST PRIZE ROCK GARDEN.

THE rock and alpine garden at Leonardslée affords much room and scope for pleasure and study, as a good number of rare and half-hardy plants are grown, many of botanical interest, my employer being especially keen and enthusiastic on all rare plants. We are year by year gradually making the garden anew on the moraine principle, using very little soil. The ingredients used were eight parts sandstone, crushed from 3 inches or 4 inches to as small as sand, one part loam, one part leaf-soil, one part granite grit and one part peat; and after three years we are convinced that the plants are making splendid sturdy growth, and are, therefore, more likely to stand the vagaries of the weather than when so much soft sappy

freely. Among them are *C. spectabile*, *C. Mackayi*, *C. Munro*, *C. holosericea*, *C. hieracifolia*, *C. grandiflorum*, *C. macrocephala* and *C. verbasetifolia*. We have several of the New Zealand plants of *Fagus tusca*, *F. Solanderi* and *F. chloroides*, which are growing nicely on the same quarter. *Kanunulus insignis* is growing freely here also, and it flowered well this spring. On another portion we have, doing well and flowering freely, *Lewisia Howelli*, *L. rediviva*, *L. Cotyledon* and *L. oppositifolia*; these, we consider, are charming plants for the alpine garden, and they have now stood out two winters. Then, we have a fairly representative collection of *Campanulas*, which include such as *C. amabilis*, *C. carpatica* White Star, *C. cenisia*, *C. alhariæfolia*, *C. Allouvi*, *C. garganica hirsuta alba*, *C. carpatica*, *C. morettiana*, *C. Raineri*, *C. raddeana*, *C. thyrsoides*, *C. Zoyssi*, *C. Hendersonii*, *C. pumila* and *p. alba*, and *C. portenschlagiana*, which make a brave show at various seasons.

A VIEW IN OUR FIRST PRIZE ROCK GARDEN SHOWING THE NATURAL SETTING OF THE STONE.

growth is made. As far as possible we plant seedlings, as these send forth a long tap-root, which goes down deeper to find moisture and gets in behind the large rocks, where it is safe from all extremes of weather.

Large masses of *Dianthus* will be noticed, and these grow with great freedom and make a good show during May and June. Among some are *D. alpinus*, *D. arenarius*, *D. barbatus*, *D. cæsius*, *D. deltoides*, *D. fimbriatus*, *D. alpinus albus*, *D. fragrans*, *D. monspessulanus* (*D. alpestris*), *D. neglectus*, *D. petraeus*, *D. plumarius*, *D. p. annulatus*, *D. Hookeri* and *D. sylvestris*. We also grow about fifty species and varieties of *Saxifragas*, including all the newer varieties, which do very well. Then, we have a nice collection of *Cytisuses*, which include all the up-to-date species and hybrids.

A collection of *Celmisias*, which are planted on a portion of the alpine garden on the north side, are doing remarkably well and flowering most

In shrubs we have a good collection of small Japanese kinds, comprising many *Piceas* and *Juniperus*; these make a nice show all through the season and break the flatness here and there. Others are some of the newer and dwarf varieties and species of *Berberis*, and a few good pieces of *B. Thunbergii*, which make a good display in the spring and have very brilliant-coloured foliage in the autumn. *Veronicas* also play a part in breaking up any flatness, such as *Veronica Armstrongii*, *V. Hectors*, *V. lycopodioides*, *V. salicornioides*, *V. cupressoides* and *V. saturioides*, making a nice display when in flower, and they also look well in winter.

In the illustration showing the waterfalls there are planted in the crevices a lot of *Ramondias*, *Saxifraga longifolia*, *Arabis*, *Aubrietias* in variety and *Omphalodes cappadocica*. On the corners of the larger rocks and on either side are large plants of *Rhododendron ferrugineum*, *R. f. album*, *R. ciliatum*, *R. racemosum*, *R. intricatum*, *Sparaxis*

puleherrima, plants of Muehlenbeckia, Olearia Gunnii, Geranium argenteum, Saxifraga granulata fl.-pl., Veronica spicata, Yucca grandiflora and Arostaphylos in variety. In the bottom, partly in water and the others in bog, there are nice plants of Platanus buxifolia, Mitraria cocinea, Primula sikkimensis, P. bulleyana, P. littoniana, Ranunculus Lyallii, Primula capitata, P. cockburniana, P. kewensis, P. rosea, P. japonica, P. pulverulenta and Pinguicula. Cypripedium acule, C. Calceolus, C. spectabile, Astilbe simplicifolia, Trillium grandiflorum, Sarracenia purpurea, Carex Grayi, C. longifolius, Spiraeas in variety, and bulbs, such as Narcissus minimus and other dwarf early species and varieties, also find a happy home there.

There is also a portion devoted to plants which require lime, and in order to give this we employ limestone in the place of sandstone, and also use a portion of gypsum in the soil when mixing it

CLIMBING PLANTS ON KITCHEN GARDEN WALLS.

[See Special Supplement.]

IN a great many gardens the walls of the vegetable department, which at one time were extensively used for the cultivation of fruit trees, have, for some reason or other, been utilised for some at least of the many good climbing plants that are now available for outdoor cultivation. Probably landscape alterations of a more or less extensive character have rendered it desirable to move the kitchen garden further away from the mansion, when, instead of pulling down the walls, they have been left and judiciously clothed with vegetation, thus affording protection to the climbers and also to

fruit trees were allowed to encroach on the view that the careful designer of flower borders in the kitchen garden will take pains to provide.

The Special Supplement presented with this issue gives a good idea of the charming effect that is obtained by clothing these openings in this way. Here we see a well-proportioned archway in the wall of the old kitchen garden at Harleyford, Marlow, where Lady Clayton has designed and obtained some delightful floral effects. This particular archway is clothed with the Mountain Clematis (*C. montana*), *Wistaria chinensis*, *Vitis purpurea* and *Vitis* or *Ampelopsis hederacea*, the whole forming a pleasant canopy to an opening through which the flower borders and grass walk are seen, a similarly clothed arch being shown at the other end of the pathway. Mr. Tipping, writing of this garden in *Country Life* a year or two ago describes it thus: "The main floral display is in the joyous and enticing pleasure which Lady Clayton has evolved out of the old kitchen garden. This consists of three walled enclosures opening on to the river on the south, but with tall trees forming a northern bulwark and background. Wide arched openings carry the visitor's eye from end to end of the whole space along a broad path which, in the middle of the central enclosure, widens out into a grass rotunda set with a boy's figure carrying a sundial and edged with seats. This long and dignified way is framed with a rich profusion of perennials, bulbs and annuals, of which the selection, the arrangement and the cultivation are all that can be desired."

In some instances parts of old kitchen gardens have been made into a more or less formal Rose garden, and then Rambler Roses naturally form the canopy to the wall opening or gateway. Such varieties as *Alberic Barbier*, *Rosa sinica*, *Anemone*, *Ards Rover*, *splendens*, or, indeed, almost any of the strong-growing ramblers, are suitable for the purpose, though, where the walls are of red brick, care must be taken that ramblers with

ANOTHER VIEW IN OUR FIRST PRIZE ROCK GARDEN, SHOWING THE JUDICIOUS ARRANGEMENT OF DWARF CONIFERS AND OTHER ALPINE PLANTS.

Several of the Primulas do better in limestone, as does that beautiful plant *Phyteuma comosum*, which is now flowering. Then there are many of the Saxifrares, Sedums, Sempervivums, Dianthus, Cerastiums, Dryas, Gnaphalums, Hutchinsias, Achilleas, Geraniums and Cyclamen; of this latter we have several nice colonies, which flower and do well under some of the low, umbrella-shaped Piceas.

As many of the alpine plants are short-lived and all sorts of ravages take place with insects, rodents, and heat and cold, a special set of frames should be set apart for propagation, and the necessary assistance should always be at hand for shading, watering and all other work which alpine gardening brings in its trail.

W. A. COOK.

(Head-gardener to Sir Edmund G. Loder, Bart.)
Leonardslee Gardens, Horsham.

the flower borders which they enclose. Another reason that may have had some influence in putting the kitchen garden walls to beautiful, if less utilitarian, purposes is the tendency nowadays to cultivate flowers by the pathways in the vegetable garden. Where such borders are formed, they provide an abundance of flowers for cutting, and impart to the kitchen garden an interest that even the best-grown vegetables and fruits are scarcely capable of doing. Usually these flower-bordered pathways run straight from the entrance to the exit, and, where such is the case, the openings or gateways in the wall afford generous support for flowering or fine-foliaged climbers, even though the rest of the wall is devoted to its original purpose of forming a shelter and support for choice fruit trees. Indeed, the general effect of the flower borders would be sadly marred

if pink or red flowers are not used, otherwise, unless the brickwork is fully clothed, there will be a clashing of colours that will offend the eye. Of climbing plants, other than those named as growing on the archway, that might be used for a similar purpose are *Wistaria multi-juga*, Japanese and European Honeysuckles, *Aristolochia Siphia*, *Polygonum baldschuanicum*, *Akebia lobata*, *Ceanothus veitchianus*, *Escallonia rubra*, most of the free-growing Clematises, *Tecoma radicans* and *Actinidia chinensis*. Before planting, the ground should be thoroughly and deeply dug and manured, and during dry weather the climbers must be given copious supplies of water. It often happens that plants which are growing against walls suffer from drought, when those in the open have ample supplies of moisture, a point that must not be overlooked.

ROYAL HORTICULTURAL SOCIETY'S SUMMER SHOW.

FAVOURED by perfect weather on the opening day, the Royal Horticultural Society held its Summer Show on July 1, 2 and 3. The exhibition was held in the spacious grounds of Holland House, Kensington, by kind permission of Mary Countess of Hechester, and by a general consensus of opinion it was considered one of the most successful in the annals of the society. The arrangement of the groups shows an advance on previous years, and the many fine examples of wall, water and rock gardens formed a charming feature of this Summer Show. Immediately the show opened, visitors poured into the grounds in exceptional numbers. To the Rev. W. Wilks (Secretary), Mr. S. T. Wright (Superintendent) and Mr. Frank Reader we tender our best thanks for their assistance, without which it would have been impossible to report this comprehensive exhibition.

HARDY PLANTS.

It is highly probable that at no previous exhibition held within the historic grounds of Holland House have hardy plants been displayed in such numbers of variety. They were there, too, in such profusion, representative of all phases of gardening in the open air, whether in the border, the rock and water garden, or what you will. It is true, however, that some of the more sumptuous or comprehensive exhibits—those embracing rock and water gardening, wall and water garden with herbaceous borders—were not to be found on so vast a scale as on former occasions, a fact due entirely to exigencies of space and the ever-increasing volume of exhibits pervading this particular field. Hence moderate-sized exhibits were seen rather than others of huge size.

Of the bolder herbaceous border groups, one of the most telling perhaps was that from Messrs. J. Box and Sons, Limpfield, Hayward's Heath, who occupied a particularly good position at the end of Tent No. 3. From a bold central group of *Thalictrum flavum* there appeared Phloxes and Delphiniums in the highest perfection, while Gladioli and Astilbes in variety were very effective. Then from a central pond appeared a galaxy of Water Lilies. Iris Kämpferi also playing an excellent part. The boldest plant in the arrangement—an excellent subject for wild gardening—was *Salvia turkestanica*.

In the same tent Messrs. W. Catbush and Son, Highgate, N., displayed a group rich in Larkspurs, Erennuri, Water Lilies and the ever-welcome Iris Kämpferi. It was most effective.

Boss, Limited, Liverpool, had some rather choice plants on a table group—*Armeria cephalotes*, Boss' Ruby, *Trollius patulus* (type), *Lupinus argenteus*, *Trollius yunnanensis* (rich golden), *Primula angustidens* (with rich flowers like those of *P. besiana*), *Campanula pusilla* Miss Willmott and *Celmia spenciana argentea*. A most interesting lot.

Messrs. Fells and Son, Hitchin, displayed a group rich in Delphiniums, Gaillardias, *Campanula pusilla* Miss Willmott (spike silky blue), *Primula bulleyana* and *P. capitata*, and a very fine mass of *Thymus Serpyllum coccineum*.

Mary Countess of Hechester (gardener, Mr. Dixon) had an unusual display of well-grown pans of *Sempervivum* (Houseleeks), some of which were quite rare. *Arachnoidium fulvum*, *cenophyllum*, *mureke*, *tomento-sum*, minor, and *Lageri Housei* are all of the Cobweb section, some quite distinct. Others noted included *triste*, *t. tricolor* and *rubundum*. There were a dozen finely-fruited pots of *Nertera depressa* in the group and a few saxifrages.

Mr. Stewart Marple, Stevenage, had a brilliantly-flowered piece of *Sedum Lydium*, together with *Campanula pusilla* Miss Willmott and *Coronilla cappadocica*, full of golden yellow flowers.

Mr. H. Newman, Watford, displayed a stand of a new double-flowered Pink which is also very fragrant. Unfortunately, like most of its race, it bursts its calyx. It is called *Challenger*.

Mr. H. Hensley, Crawley, included rockwork, border plants and alpines in a rather extensive exhibit. Of particular interest was a series of hybrid *Aurifimums*

raised from crossing *sempervivum* and *maius*. Some are very pretty, and numerous colour shades are represented. *Hydra acutis* (rich yellow and only 2 inches high), *Waldenbergia vineiflora*, *Viola hederacea*, *Lychnia Henryi* and the pretty-flowered *Coris monspeliensis* were also noted in an interesting group.

Messrs. Pullham and Sons, Elsenham, had some pretty hybrid *Dianthi* of the taller border sorts, such as *Elsenham Seedling* and hybrids of *annulatus*. *Eschalloua langleyensis*, with blood red flowers, was very fine, and so, too, were *Andromeda speciosa* and *Campanula* Miss Willmott.

In the open Messrs. Watkins and Simpson, Laycock Street, W.C., arranged a group of *Nemusas* and *Aurifimums*, all being grown in pots. Blue Gem and Triumph were the best of the *Nemusas*, while White Queen among the *Snaphagons* was as good as any. *Lobelia tenuior*, tall of habit and exceedingly rich in colour, was most effective.

Mr. Amos Perry, Enfield, had a great display of Delphiniums, hardy Petros and other plants. The best of the Larkspurs were Eric Kingscote in fine masses, Perry's Favourite, Moorheim (white), Camen and gloriosa, *Campanula Bowles' Hybrid* is a fine lot of colour. Hybrid of *Phlox Ardeni* were notable, while *Salvia hibernica* is perhaps the only yellow-flowered species of its genus in the herbaceous section.

Mr. M. Pritchard, Christchurch, had a particularly bold display of rock and herbaceous gardening in which Larkspurs, *Spirea palmata*, *Waldenbergia vineiflora*, and *Lavatera Oliva* were prominent items. Many choice alpines were employed, the Lewises calling for special remark.

Messrs. Wallace and Co., Colchester, had this time to be content with a smaller space, utilising it well, however, with a wall and water garden arrangement and a telling bank of herbaceous flowers. The latter was rich in Lilies, also *Hemeroclas* and *Erennuri*. *Calochortus Vesta* made a great show, while *Erodia coccinea* was exceptionally brilliant in colour. The water garden portion was very naturally disposed, and the varieties of Iris Kämpferi that were boldly grouped by its margin were very fine, particularly Morning Mist, a huge flower with white flushed lavender petals.

Messrs. James Veitch and Sons, Limited, Chelsea, had a great gathering of Erennuri, also Astilbes, the pure white *A. grandis* making a notable plant among the rest.

Messrs. Jackson and Son, Woking, staged a very showy lot of herbaceous things, Irises, Delphiniums, Campanulas, Gaillardias and other seasonal flowers. *Tunica Saxatana alba* was very pretty.

Messrs. G. and A. Clark, Limited, Dover, displayed Larkspurs, Pentstemons, early Gladioli, *Liliums* of sorts, Erennuri, the fine violet and white Delphinium Rev. E. Lascelles, *Salvia turkestanica* and the like.

Messrs. Phillips and Taylor, Bracknell, had a particularly good piece of water gardening in conjunction with herbaceous border grouping. Such Water Lilies as *Nymphæa carnea*, *gladstoneana* and the rich red William Falconer were very good. Many other aquatic and waterside gardening plants were employed with good effect.

Messrs. T. S. Ware, Limited, Feltham, had a capital grouping of herbaceous flowers, with a narrow pool for aquatics and allied plants, fronting the arrangement with choice alpines. Astilbes in variety, with great masses of Iris Kämpferi, played their part uncommonly well.

Messrs. Carter and Co., Raynes Park, in the open, had a fine Japanese garden, with pool, paved way, walks and wall garden. At the back were many Rose pyramids, while around the pool hundreds of Iris *kevignati* (Kämpferi) showed these fine plants to advantage. The Irises alone were quite a feature, and were greatly admired.

Baker's, Wolvthampton, had a particularly bold ground group of herbaceous flowers, finishing it down to the edge with the more minute growing subjects. English Irises, Delphiniums, Gaillardias and all the border things in season were noted. Dwarf Campanulas and *Thymus Serpyllum coccineum* were prominent features in the foreground.

Messrs. Paul and Son, The Old Nurseries, Chelsea, displayed a table group of hardy cut flowers, *Hemeroclas*, *Eryngium*, *Verbena* and *Astragalus* being noted among the bolder masses of things.

Messrs. Blackmore and Langdon, Bath, had a group entirely composed of Delphiniums of the finest quality. *Statuaire Rude*, *Lilacina*, *Moerheimi* (white), *Lord Curzon* and *Rev. E. Lascelles* were perhaps the most striking of all. The Larkspurs were particularly well shown.

Mr. G. Reuther, Keston, Kent, arranged an extensive exhibit of Lilies, choice shrubs and alpines. The Erennuri were very telling, and some fine masses of *Erica cinerea* told their own tale.

Messrs. Lilley Guinness, arranged a most graceful exhibit of early Gladioli, *Speraxia* and *IXIAS*, the *Speraxia* constituting a most graceful and pleasing item, and, moreover, are much too rarely seen.

The extensive group of hardy herbaceous flowers from Messrs. G. Bunyard and Co. was among the finest of the table groups the show contained. Masses of Lilies,

Erennuri, Delphiniums, Gaillardias, Astilbes and Campanulas each played a part well. The group was most effectively arranged.

Messrs. Bath, Limited, Wisbech, had a group of the choicest Delphiniums, Clara Stubbs, Lizzie, Cores, and King of Delphiniums being all distinct and good.

Messrs. Kelway and Sons, Langport, also had a group rich in the Larkspurs they grow so well, the bold and telling spurs of the flowers creating a fine effect. Beauty, Lady Fair Star of Langport, Lovely, Magnificent and Lord Wondell were among the more striking. Single *Ermones* were also on view and were very beautiful.

Messrs. Gunn and Sons, Olton, Birmingham, staged herbaceous Phloxes in their accustomed manner. Flora America, Elizabeth Campbell, G. A. Stroheim, Lady Stewart, Ellen Willmott and Mrs. Oliver were all good and distinct. This Phlox group was one of the most telling in the show.

The Messrs. Hopkins, Shipperton-on-Thames, had a small, prettily arranged group, in which Campanulas, *Viola Hopkinsi* and other choice plants were seen.

Messrs. Whitelegg and Page, Chislehurst, displayed effectively Campanulas, *Potentilla* Miss Willmott, Astilbes, Larkspurs and Irises.

Mr. J. Smith Woodbridge, had a showy lot of Gaillardias, *Verbascum*, Delphinium Mrs. Coughton and other plants.

John Forbes, Hawick, Limited, arranged in the open a very showy lot of hybrid Pentstemons, Phloxes and other things, the whole creating a fine spectacle near the entrance.

ALPINES AND ROCK GARDENS.

Mr. Reginald Fairhead, West Meors, Whitborne, arranged a small table group of alpines, in which the brilliant *Potentilla* Miss Willmott, *Campanula garganica hirsuta*, *Scutellaria indica japonica* and *Eubranthos dalmatica* were among the more prominent features.

The rock garden in Tent No. 1 arranged by Messrs. Piper and Sons, Bayswater, was one of the great features of the show, the finest and most naturally disposed of any rock garden this firm has ever attempted. It was, if we may say so, a possible piece of work, one that it transferred bodily to the open garden would have rendered alpine plant-growing a quite possible thing. Not a few of those we see are just the opposite, more of the plant cemetery business than anything else. Cheddar limestone was employed, its grey colour lending itself admirably to such work. We think it was the perfect naturalness and simplicity of the arrangement which appealed to us most strongly. The choicest plants were employed, and those the re-flowering subjects, like *Thymus Serpyllum coccineum*, were a great charm. A crevice filled with *Sempervivum arachnoidum* was very fine.

Messrs. Cheat and Sons, Crawley, had a pretty rock wall and rock garden arrangement with paved walk and the like, all delightfully planted, and presenting a type which is of much service in the garden. The filling of crack and crevice was very pleasingly done.

Mr. Clarence Elliott, Stevenage, had a table rockwork arrangement outside Tent No. 2. Prominent features were *Campanula pusilla* Miss Willmott, a very deep violet-coloured form of *C. hirsuta*, not more than 9 inches high, with *C. pulla*, *Waldenbergia vineiflora*, the pretty *Arborescent Sedum*, *S. hebrannianum*, and other plants.

Messrs. Piper, Bayswater, in the open, had a wall and terrace garden surrounded by clipped trees, in conjunction with a water pool and a choice assortment of Lilies and Rose trellis at the back.

The Wargrave Plant Farm, Twyford, arranged alpines in groups on a table space in the open, employing many choice and useful plants. *Sedum cereuleum* was very beautiful, while colonies of *Coronilla cappadocica*, *Campanula garganica* in variety and C. G. F. Wilson were also noted.

Mr. G. Reuther, Keston, Kent, had a table group of alpines in the open, replete with choice plants. *Rhododendrons* *daphnoides* and *hirsutum* were good among shrubs, while *Anthyllus chrysanthus*, *Campanulas* in variety, inclusive of the rare *C. raddiana*, *Erica cinerea pygmaea*, *E. c. alba* and *E. c. rosea* gave sheets of colour of the most charming kind. *Edelweiss*, *Sedum sulphureum*, *Umbilicus Semenovi* and *Silene Elizabethae* were notable among other things.

Mr. Charles Bassell, Earl's Court Road, contributed a small enclosed rock garden, with paved walk, all pleasingly planted and arranged with rock, alpine and shrub. It was most effective.

The rockwork which Messrs. Barr and Sons, Covent Garden, set up in Tent No. 1 was a great attraction, weathered mountain limestone being employed, and, arranged close upon the ground, gave evidence of much thought and care. Such Campanulas as *raddiana*, *C. pusilla* Miss Willmott, *C. turbinata*, and *C. rotundifolia* Ditton Gem were all employed in free colonies, and in conjunction with water and supported by the best herbaceous plants made a comprehensive and telling feature.

MISCELLANEOUS STOVE AND GREENHOUSE PLANTS.

Messrs. James Veitch and Sons, Limited, Chelsea, put up a splendid exhibit of the choicer greenhouse flowers for which they are noted. These were arranged in blocks of each kind, so that their prominent characteristics were very noticeable. Mahanias Carnations were very fine, as also were the rich Tyrian blue-flowered *Exacum macranthum*, *Sollya Drummondii* (the Blue Bell Creeper of Australia), *Solanum Wendlandii* (a number of perfect examples), *Begonia Lazerna* and *Cannas* in variety. These formed such a gorgeous feature that the names of a few of the best are herewith appended: J. B. Van der Schoot (golden yellow, spotted crimson), *rosa gigantea* (deep rich rose), Niagara (frod, margined gold), Duke of York (crimson, gold border), Frau E. Kraehl (rosy salmon), *Sturtteartaia* (scarlet and orange, edged light yellow), Duke Ernst (reddish scarlet) and Furst Weid (deep crimson).

From Messrs. John Peed and Son, Norwich, came a fine group of specimen *Caladiums*, all bearing evidence of great care and attention in their cultivation. Two new varieties stood out markedly, namely, Red Indian (rather small leaves of a brilliant scarlet red with a narrow green edge) and Crested Wave (a transparent white leaf with green veins and edges). Of other kinds may be especially noted Henry Lovatt (red, freckled, green edge), Mme. Mitjana (intense self crimson), Mrs. Harry Veitch (dark red), Sir Henry Irving (creamy white, green margin, rose veins) and Her Majesty (bright green and white, tinged carmine). The *Gloxinia* and *Streptocarpus* from Messrs. Peed were also particularly good.

Messrs. Blackmore and Langdon, Fwerton Hill Nursery, Bath, are unsurpassed in the culture of the tuberous-rooted *Begonia*. Their exhibit, consisting solely of double-flowered varieties, fully upheld the great reputation they have so long enjoyed. Of especial note were Queen Mary (light rose pink), Lady Tweedmouth (salmon pink), Irene Tambling (brilliant orange), Rose Queen (rich rose), Princess Victoria Louise (pale flesh pink), Duchess of Cornwall (rich crimson), Mrs. Robert Morton (yellow, with an amber shade) and Empress Marie (pure white). Besides these were some of the drooping kinds so useful for suspended baskets, namely, Golden Shower, Mrs. Bilkey, Ruby, Rose Cactus and Gladys.

From Messrs. R. and G. Cuthbert, Southgate, came a group in which *Humea elegans* figured largely. Other subjects which were also freely represented included *Streptosolen Jamesonii*, *Lilium longilobum*, and that exceedingly showy annual known as *Viscaria oculata* and *Lycinus colli rosea*.

Mr. L. R. Russell of Richmond showed a fine collection of indoor subjects, mainly consisting of fine foliage stove plants, such as *Crotoms*, *Trapaenas*, *Alpinia sandieriana*, *Anthurium Veitchii*, *Sonerilias*, *Marantias*, &c. Of greenhouse subjects there were large batches of *Salvia Glory of Richmond*, remarkable for its bright-coloured blossoms; *Nertera depressa*, which Mr. Russell induces to fruit in such a remarkable manner; and *Abutilon Sawitzii*, whose variegated leaves are so much appreciated for various decorative purposes. A large batch of the uncommon *Nicotiana collosa variegata*, with immense soft green leaves bordered with light yellow, formed a very striking feature.

Mr. W. H. Page, Tangley Nurseries, Hampton-on-Thames, showed large hemispherical groups of the three varieties of Zonal Pelargoniums for which he is so noted, namely, His Majesty, Fiscal Reformer and Winter Cheer. Besides these, smaller groups of the following desirable kinds were shown: Barbara Hope, salmon; Venus, white; and Her Majesty, very bright salmon.

Messrs. Godfrey and Son, Exmouth, Devon, contributed an interesting collection of Pelargoniums, in which all the different sections were represented. The scented-leaved varieties, which are again becoming popular, were well shown. Besides the Pelargoniums a prominent feature of this group was a number of dwarf flowering plants of *Solanum Wendlandii*.

An unusual exhibit was a large number of the different varieties of *Crassula coccinea* from Lady Northcliffe, Sutton Place, Guildford. Besides the richly coloured forms there were several of softer hues, and exceedingly pleasing they were. Such an exhibit of this good old plant should lead to its extended cultivation, as for greenhouse decoration its merits rank high.

Messrs. William Cuthbert and Son, Highgate, put up a large collection of flowering subjects, Hydrangeas in blue, white and pink being freely represented. Of these a new variety, La Perle, with large white flowers serrated at the edges, was very striking. Another variety with huge blossoms was *Beauté Vendemoise*, whose colour is pale mauve. Besides the Hydrangeas there were also flowering *Cannas* in great variety, the tree-growing *Begonia corallina*, B. Bertini (a tuberous-rooted variety in great request for bedding) and *Colobis Gordia* (which as a decorative subject has become exceedingly popular within the last few years).

Bottle Brush Flowers formed the predominant feature of a collection put up by Messrs. Stuart Low and Co., Bush Hill Park, Enfield. There were in addition Pelargoniums of different kinds, the whole being edged with that pretty free-flowering plant, *Heera elegans*, whose bright ruby-coloured blossoms were much admired.

Mr. A. L. Gwillim, Cambria Nursery, Sidemp, showed a collection of tuberous-rooted *Begonia*, for which he is justly noted. They were all double-flowered varieties, many fine kinds being represented. Particularly noticeable were *Sidemp Beauty* (soft pink, much fringed), Mrs. Maribel Edmondson (light salmon, shaded cream), Mrs. Harris (salmon scarlet), *Pride of Eltham* (crimson), Margaret Gwillim (beautiful yellow) and *Avalanche* (white).

Messrs. James Veitch and Sons, Chelsea, put up a group of *Astilbes* and *Spiraeas*, in which the various coloured kinds were freely represented. While of considerable value in themselves from a decorative point of view, these *Spiraeas* also served as a desirable groundwork for a display of a number of cut spikes of different forms of *Eremurus*.

Messrs. James Carter and Co., Raynes Park, had a small tent to themselves of various seedling subjects, among which were several hardy annuals, and in addition a good collection of *Streptocarpus* and tuberous-rooted varieties of *Begonia*.

An exhibit of cut flowers of Zonal Pelargoniums from Messrs. H. Cannell and Sons, Swanley, was put up in their well-known style, and contained a choice collection of varieties.

Messrs. Jarman and Co., Chard, Somerset, contributed, in addition to their *Centaureas* and other herbaceous plants, a number of cut flowers of Zonal Pelargoniums, which were exceedingly bright and cheerful.

Pelargoniums of different sections were also shown by Mr. W. Treseder, The Nurseries, Cardiff, many of the show varieties being very fine. Among them was the exceedingly dark-coloured variety, Lord Bute, which received an award of merit two years ago when the Summer Show of the Royal Horticultural Society was held at Olympia.

A representative collection of *Fuchsias* was shown by Messrs. J. Piper and Sons, Bishop's Road, W. Dwarf plants, tall pyramids and lofty standards were all there in considerable numbers, the selection of varieties being a good and comprehensive one. Taken altogether, this was a decidedly uncommon exhibit.

Mr. W. A. Manda, St. Albans, Herts, put up a group of decidedly uncommon plants. The distinct and showy Fern *Polypodium mandaiianum* was well represented, its good reputation being well maintained. Besides this were the graceful-habited *Asparagus elongatus*, which has proved of considerable value for decorative purposes, and *Anthurium mandaianum*, well suited for growing in suspended baskets, the dark green recurving leaves having a central band of yellow. The curious *Alcocia fassalliana*, a new species of tall and stately habit, with leaves considerably cut, was also noted in this group. Besides the subjects above referred to, there was a collection of hardy North American Cacti.

The only collection of exotic Ferns was contributed by Messrs. H. B. May and Sons of Edmonton. It was a very charming group, and well upheld the reputation of the firm for the culture of this beautiful class of plants. The bulk of the exhibit was made up of good representative specimens of the finest decorative Ferns. *Davallias*, *Polypodiums* and *Adiantums* were freely represented, but in such an extensive collection it is difficult to select any for special mention. A very fine form of *Adiantum* (trapeziform bearing the name of Queen Mary) must not, however, be passed over, it being in every way very fine. Many of the smaller-growing kinds employed as an edging were very beautiful, and a small group of that extremely mossy variety of *Nephrolepis exaltata* was the admiration of everyone. The *Lygodium*, too, were very striking.

Mr. Amos Perry of Enfield showed a group of hardy Ferns, not made up of curious or depauperated forms, but consisting of fine, bold-growing kinds, all of which are of great decorative value. They were so attractive as to suggest that hardy Ferns are very likely before long to regain their old-time popularity.

ORCHIDS.

As in former years, Orchids attracted a deal of attention, and the massive banks of *Cattleyas*, *Odontiodas*, *Phalaenopsis* and *Miltonias* in many beautiful colours evoked great admiration from the constant stream of visitors who passed by.

Messrs. Charlesworth and Co., Hayward's Heath, were there with a wonderful display of *Odontoglossums* and their choice relatives, *Odontiodas*. A remarkable plant of *Cattleya gottiana* The President, with trusses of large rosy pink flowers with deep crimson lips, was one of the gems of the collection. *Epidendrum vitellinum majus*, with orange-tinted flowers, and *Dendrobium Pearl*, with masses of white flowers, were both well shown. Of plants of botanical interest we observed the Holy Ghost or Dove Orchid, otherwise known as *Peristeria elata*, and *Grammiaensis Ellisii*.

Two bold groups of *Cattleya gigas*, with immense and highly-coloured flowers, shown in Messrs. Sander and Son's collection from St. Albans, were really one of the outstanding features of the Orchid tent. The same firm showed *Phalaenopsis* in suspended baskets, from which the arching sprays of white flowers hung down in wild profusion over a groundwork of *Miltonia vexillaria* Empress Augusta. Many choice *Odontiodas* were shown in the foreground. The collection was staged in a masterly and effective manner.

From Sir Jeremiah Colman, Bart., Gatten Park, Surrey (gardener, Mr. J. Collier), came a very interesting collection, in which the golden yellow *Laelio-Cattleya Phoebe* stood out well among the white flowers of *Phalaenopsis rimsteadiana*, *Odontoglossum Pescatorei* and *Odontodia Bradshawe* were both shown in superb condition, while *Miltonias* *bleuana*, *lambeanum* and *vexillaria* in variety were shown to perfection.

Mr. E. V. Low, Vate Bridge, Hayward's Heath, had a group of choice Orchids, in which we observed the curious *Medusa Head*, or *Nanodes Medusa*, and *Eulophyllum* *hamburgeri*, with hinged lips that sway in the lightest breeze. *Cattleya Mossie Wagneri* and a variety of *Cypripediums*, such as *callosum* *Sanderi*, *Maudie* and *schiedhamum*, were included.

Messrs. Mansell and Hatcher, Limited, Rawdon, Yorks, had a magnificent display of *Cattleyas*, mostly of the

gigas type, with banks of *Laelio-Cattleya Eudora* and *Aphrodite* at each end. *Cattleya Mossie Wagneri*, with large white flowers, tinted yellow on the lip, was shown in perfect form. *Miltonias* were also fine, notably the large *M. vexillaria* *Queen Alexandra* and *M. bleuana nobilior*. *Odontiodas*, *Disas* and *Phalaenopsis* all contributed to a very interesting and well-grown collection.

Mr. Harry Dixon, Spencer Park Nursery, Wandsworth Common, had a nice group, in which *Odontiodas*, *Cattleya* hybrids and *Odontoglossum Pescatorei* were represented.

Mr. S. W. Flory, Tracy's Orchid Nursery, Twickenham, had a bank of *Cattleyas*, mostly of the Mossie section. *Laelio-Cattleya canhamiana* and *Miltonia vexillaria* were well shown.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, had an extensive and well-arranged group, in which the white sprays of *Phalaenopsis* contrasted with the intense scarlet of *Renanthera muschotiana*. Among the gems of the collection were *Cattleya dupreana* *Gorgeous*, *Laelio-Cattleya Eudora* *Crowborough variety*, *Phalaenopsis rimsteadiana* *alba* (with pure white flowers), *Cattleya Wagneri*, C. Mendelli *La Vierge* and C. Mossie *Wagneri* *Princess Mary* *Mertchersky*. Some grand forms of *Cattleya gigas* were on view, also *Dendrobium thyrsoides* with immense flower-spikes.

ROSES.

In the group staged by Mr. C. Turner of Slough we noticed some very fine blooms, Coronation, a new rambler with scarlet flowers, being very bright. Ethel, a pink-flowered rambler, was also charming. Mr. Turner also had a sport from *Lyon Rose*, this being a semi-double variety with spreading habit and bright buff-coloured flowers. Hugh Dickson, Lady Hillingdon, Rayon d'Or, Duchess of Wellington and many other sorts were also well shown.

Messrs. William Paul and Son of Waltham Cross had a magnificent group of weeping standard and cut Roses, these including all the latest and best varieties. *Beauté de Lyon*, Arthur R. Goodwin, Rayon d'Or, Mme. Segond Weber, Lyon, Juliet, Hugh Dickson, Marquise de Siney, Hawatha, Tausendschön and White Dorothy Perkins were only a few of the many good Roses to be seen here.

Hobbies, Limited, Derham, Norfolk, had a large group composed of weeping standards and baskets of cut blooms. Rayon d'Or was specially good, and Pink Pearl (a large single), Danie (a perpetual yellow-flowered rambler), Lyon, Betty, Mme. Melanie Souper, Effective (semi-double crimson with large flowers) and Lady Hillingdon also called for special mention.

Mr. George Paul of Chestnut had a magnificent bank of cut blooms, pillar Roses and weeping standards, the whole being fresh and of good colour. Sunburst, Captain Hayward, Lyon Rose, Excelsa, Mrs. David McKee, Mme. Melanie Souper, Beauté de Lyon, Shower of Gold (a new rambler with small yellow flowers) and George C. Waud were a few of those that called for special mention.

In the large group staged by Messrs. Stuart Low and Co. of Bush Hill Park, Enfield, we noticed many very good flowers, such varieties as Rayon d'Or, Sunburst, Commander Jules Gravereaux, Leshe Holland, Arthur R. Goodwin, Chateau de Clos Vougeot, Lady Pirrie, Harry Kirk, Duchess of Wellington, Molly Sharmar Crawford and Pharisæe being particularly fine.

The Rev. L. C. Chalmers-Hunt, William Rectory, Hitchin, had a small but interesting exhibit of Roses, these including good blooms of such favourites as Mrs. John Laing, Frau Karl Duschki, Mrs. W. J. Grant and Lyon Rose.

Messrs. Frank Cant and Co., Braiswick Rose Gardens, Colechester, put up a very fine bank of Roses, these including a great many of the newer sorts. Rouge Angevine, a Hybrid Perpetual with large, semi-double, brilliant scarlet crimson flowers, formed a good centre to the group, and other noticeable sorts were Mme. Melanie Souper, Lyon Rose, Rayon d'Or, Miss Ada Frances (a new rambler, with flowers resembling those of Goldfinch, but much freer than that variety), and Braiswick Chrome (a new *weichuriana* with reflexed flowers of yellow hue).

Messrs. George Jackson and Sons of Woking used rambles as a background to their group, cut blooms in tall vases and boxes being well shown in front. All were clean and good, Hugh Dickson, Le Progrès, Rayon d'Or, Lady Alice Stanley and Lady Ashdown attracting much attention.

Messrs. Benjamin R. Cant and Sons, Old Rose Gardens, Colechester, put up a very large and attractive group, rambles and show varieties being included in great profusion. Mrs. Alfred Tate, Lady Hillingdon, Molly Sharmar Crawford, J. B. Clark, Killaroy, Rayon d'Or, Betty, Warner, American Pillar and Edward Mawley were a few among many specially good sorts.

Mr. W. Easlea, Daneroff Roseery, Eastwood, Essex, had a charming little group of clean and well-coloured flowers. Cherry Page, a new decorative Hybrid Tea, formed a fine centre, the semi-double flowers of cherry pink, shaded yellow, being most attractive. Ethel, a new rambler with small pink flowers, Marquise de Siney, Chateau de Clos Vougeot, Arthur R. Goodwin and Rayon d'Or were others that called for special mention.

Messrs. Morse Brothers, Deben Nursery, Woodbridge, had a good group of cut blooms, Juliet, Rayon d'Or, Orleans Rose and General MacArthur being very bright and attractive.

In the small but good group put up by Mr. John Mattock, New Headington, Oxford, we noticed excellent blooms of Irish Elegance, Marquise de Siney, Mrs. T. Roosevelt, Mme. Segond Weber and George C. Waud, the colour of all being exceptionally good.

Mr. R. C. Nottcutt, Woodbridge, exhibited a large and comprehensive group of cut Roses, among them being such good sorts as George C. Waud, Mrs. David Jardine,

A CREEPER-CLAD ARCHWAY,

With Herbaceous Borders in the back-ground, at Harleyford, Buckinghamshire.

Mrs. Wakefield Christie Miller and Juliet, the whole being put up in good condition.

Messrs. G. Bolton and Son, Buntingford, Herts, had a large group of rambler and other varieties, including such sorts as Hugh Dickson, Mrs. Aaron Ward, Nita Weldon and George C. Waud.

The large bank of cut blooms staged by Messrs. W. and J. Brown of Peterborough was very attractive, the arch of Lyon Rose that formed the centre making a wonderful bit of colour. Prince de Bulgarie, Marquise de Smetty, Lady Pirrie, Harry Kirk, Rayon d'Or and Joseph Hill were others that added to the charm of this exhibit.

Mr. George Prince's group from his Oxford Nursery was well up to his usual high standard, being well arranged, clean and bright. His Lyon Rose was a wonderful colour, and Avoca was superb. Gardenia, Lady Pirrie, Mme. Melanie Soupert, Rayon d'Or, Blush Rambler and American Pillar were others that attracted considerable attention.

SWEET PEAS.

These were a great feature at this fine show, the flowers being in remarkably fine condition considering the season.

A capital lot of this fragrant annual was shown by Mr. James Box, Lindfield Nurseries, Hayward's Heath, Sussex. The colour was good, the quality all that one could well desire and, except for the little crowding, this exhibit was highly commendable. Varieties worthy of special mention were Thomas Stevenson, Maud Holmes, Rosabelle, Money-maker, R. F. Felton, Elfrida Pearson, Dobbie's Cream, Mrs. Gibbs Box (superb), Orange Perfection, Blue Belle (lovely), Mrs. Handcastle's Sydes Empress and James Box (gorgeous).

A very large and comprehensive display of Sweet Peas was shown by Sir Randolph Baker, Bart., M.P., Ramston, Blandford (gardener), Mr. A. E. Usher, a superbly fine were the flowers in every particular. Colour, form, freshness, length and stoniness of stems, all were shown in a high state of perfection, and the setting up of the flowers in the vases and stands showed considerable skill and artistic ability. Specially good were the following varieties: Edrom Beauty, Anglian Orange, Lady Miller, Princess Victoria, Barbara, Mark's Toy, Marjorie Linzee, May Campbell, Audrey Crier, Mrs. W. J. Unwin, Lady Evelyn Eyre, Lavender George, Herbert, Dobbie's Cream, Azulea, Senator Spencer and Mrs. Cuthbertson. There must have been nearly one hundred and fifty stands in this remarkable exhibit.

Messrs. Barr and Sons, Covent Garden, W.C., had a few bunches of Sweet Peas with other hardy flowers, and this collection included several popular sorts.

Most attractive was the large and artistic group of Sweet Peas from Messrs. Sutton and Sons, Reading. In all there were about one hundred and twenty varieties, duplicated in several instances, so that the display was a very large one. The background was adorned with huge stands set up in attractive fashion, and what was most noteworthy in this exhibit was the colour of the flowers. Each colour was represented at its best, the richer tone being most gorgeous. We must not omit to mention some of the varieties that stood out distinctly for their general excellence. They were the following: Dorothy, Mrs. Cuthbertson, Rosabelle, Scarlet Empress, James Box, Sunproof Crimson, Elfrida Pearson, Barbara (superb), Earl Spencer, Lady Evelyn Eyre, Hercules, Florence Wright Spencer, Senator, May Campbell, Constance Oliver, Helen Grosvenor, Mrs. Townsend, Mrs. W. J. Unwin, Scarlet Empress, Queen of Norway, Bertie Usher, W. P. Wright and Thomas Stevenson.

Messrs. Dobbie and Co., Edinburgh, well maintained their reputation as Sweet Pea experts. The flowers in a large group of Sweet Peas set up in vases and stands being remarkable for their superb quality. The flowers were large, beautifully fresh, quite in character, and noteworthy for their colour and freshness—they were without a blemish. Especially good were Inspector, John Ingham, Dobbie's Cream, Edna Unwin (glorious), Elfrida Pearson, Maud Holmes, Dobbie's Blue Phoenix, Hugh Dickson, New Marjorie (superb), Mrs. C. W. Broadmore, Elio Herbert, Lavender G., Herbert, R. F. Felton, Lady Knox, Mrs. Cuthbertson and Grey Lavender.

A pretty group of Sweet Peas was set up by Mr. J. D. Webster, Chichester. The group was not large nor very well arranged, but it included a number of the newer and more popular varieties.

A display of Sweet Peas was set up by the Rev. E. C. Chalmers-Hunt of Willian Rectory, Hitchin. There were about forty vases, and for an amateur the display was highly creditable. The quality of the flowers was generally good.

A bright and attractive display of Sweet Peas was made by Messrs. John K. King and Sons, Coggeshall, Essex. There were in all about seventy-two vases and stands, and the flowers were beautifully fresh and of good colour. Nettie Jenkins, Mrs. Hestington, Prince Edward of Wales, Mrs. C. W. Broadmore, Mrs. Cuthbertson, Hercules, Loyalty, Prince George, R. F. Felton, King Alfred, Maud Holmes, Elfrida Pearson, Mark's Toy and Isabel Malcolm were all good.

Robert Sydenham, Limited, Tenby Street, Birmingham, set up an exhibit of Sweet Peas, with dainty Maidenhair Ferns interspersed between the vases. Lady Evelyn Eyre, Maud Holmes, Edith Taylor and other good sorts were in evidence.

A pretty display of Sweet Peas came from Messrs. E. W. King and Co., Coggeshall, Essex, which lost in some measure owing to the formal and stiff arrangement of the flowers. They were bright and fresh, and included, among other varieties, good examples of Hercules, Rosabelle, Anglian Orange, Anglian Lavender, and Anglian Royalty (a quite unique Petunia shade), very distinct.

A dainty exhibit of Sweet Peas came from Messrs. A. Stark and Son, Great Ryburgh, Norfolk. Grasses, &c., were added, which is now very unusual, and it is questionable whether they added to the beauty of the display. Hercules, Improved Olive Ruffell, Thomas Stevenson, Lady Northcliffe (grown under glass), Maggie Stark, Nell Gwynne Spencer and Mrs. Cuthbertson were the better varieties.

A capital series of stands and vases of Sweet Peas was set up by Messrs. S. Bide and Sons, Farnham, Surrey. Although not one of the largest exhibits, the display was highly creditable. The flowers were very large, fresh and clean, and represented culture of the best. Edna Harland, Clara Curtis, Edith Taylor, R. F. Felton, May Campbell, Dorothy, Princess Mary (Bide's), Mrs. Cuthbertson and others were very fine.

In a specially-erected tent Messrs. James Carter and Co., High Holborn, W.C., displayed, among other subjects, a beautiful collection of Sweet Peas in large and handsome bunches arranged in vases. Among the good things to be found here were Helen Lewis (still good), Mrs. C. W. Broadmore, Thomas Stevenson, Anabel Lee, Earl Spencer, Hercules, Duplex Spencer, Mrs. W. J. Unwin, Florence Nightingale, Kathleen and Elfrida Pearson.

VIOLAS AND PANSIES.

One corner of No. 2 Tent was occupied with a very large and comprehensive group of bedding Violas and Violettas, set up in attractive fashion in pans of silver sand and hardy foliage. Of the Violas, conspicuous sorts were Kathleen, May Cymbal (a good white), Swan, Mrs. Sander, Mrs. B. Eric South, Royal Purple, Royal Blue, Mrs. E. A. Cade, Ethelred, Reggie, and a host of other good things. The Violettas were really very charming. Mr. Howard B. Crane, Woodview, Highgate, N., who made this exhibit, has specialised in these beautiful rock garden plants, and they are destined to be largely used in the not distant future. Specially noteworthy were the following sorts: Rock Linton, Rock Orange, Rock Yellow, Purity, Eden, Chathin, Butterfly, Primrose Beauty, Forget-me-not, Mollie, Sweetness and Estelle.

Fronting the group of Pont-stenons and Philoxers from John Forbes, Hawick, Limited, were quite a number of popular Violas. Noteworthy sorts were James Pilling, Campbell-Bannerman, Mary Birnie, Snowflake, Mrs. C. F. Gordon, President, Mrs. Chichester, Duchess of Sutherland and W. H. Woodgate. The flowers and growths on which they were developed gave evidence of having been grown in a cool, moist climate.

A very fresh and attractive lot of Violas, set up in pans, was shown by Messrs. Carter Page and Co., London Wall, E.C. Considering the trying weather of late, the flowers were in a remarkably good form and condition. Noteworthy examples of these useful flowers were G. C. Murray, Harry Bamber, Ophelia, Jessie L. Arbuckle, Mossley Perfection, Winchmore Blue, Lizzie Stone, Purple Eddier, Kitty Bell and James Pilling.

A mass of Viola cornuta purpurea and an interesting lot of Violas were shown by Messrs. Rich and Co., Bath. We thought we had seen the last of exhibits of Violas in spray-like form in, say, half-a-dozen blooms of each variety. The Violas were poor and shriveled in many instances. Quite refreshing, however, was the purple form of *V. cornuta*.

A small lot of Violas and the *Pyramis* species were shown by Mr. G. W. Miller, Wisbech, Bridal Morn, Swan and Mossley Perfection were the better Violas.

CARNATIONS.

Messrs. W. Curbush and Son, Highgate, N., and Barnett, E.C., occupied one corner of the big tent with a group largely made up of Carnations and a few good Pinks. Mounds and vases were most tastefully arranged with Malmison and Perpetual-flowering Carnations, and in this way they were seen at their best. Mrs. C. W. Ward, Eucrautes, White Wonder, May Day and Florence McLeod were a few of the better Perpetual-flowering sorts, and among the Malmisons we noticed Marmion, Lady Coventry, Maggie Hodgson, Haldwin, Mercia, The Queen, Princess of Wales and Lady Grimston. This was a capital exhibit, and did the firm great credit.

A beautiful arrangement of Carnations in bud, vases, bowls and stands was set up by Messrs. Stuart Low, Bush Hill Park, Enfield, Middlesex, in their exhibit. Of the Malmison type, Blush Malmison, Princess of Wales, Maggie Hodgson, Sir Evelyn Wood, Lady Coventry, Lady Arthur Butler, Jane Seymour, and a fine variety, seedling represented these handsome flowers in fine form and condition. There were many representatives of the Perpetual-flowering Carnations, all arranged in vases in a groundwork of beautiful Ferns.

Very artistic indeed was the group of Malmison Carnations from W. M. Gott, Esq., Fenchurch, Ear Station, Cornwall. As an example of an amateur's exhibit this was very good indeed. By the tree use of Smilax, arranged on strained gauze, and a groundwork of Ferns, the effect was distinctly dainty. The Carnations were arranged in vases, and included, among others, the following varieties: Princess of Wales, Mrs. Trevelyan, Mrs. Torrens, Maggie Hodgson, Improved Duchess of Westminster, Blush Malmison, Mrs. Wilfrid Gott and King Oscar.

Malmison Carnations from Messrs. James Veitch and Sons, Limited, Chelsea, S.W., made a bright table group. The flowers were very fresh and in capital condition, Mercia, Duchess of Westminster, Maggie Hodgson, The Colonel, H. J. Jones, Princess of Wales, Souvenir de la Malmison and Lyndale were all not worthy.

From Mr. James Douglas, Elmside, Great Bookham, came many superb border Carnations, for which this raiser

is so famous. Virginia award of merit, Renown, The Baron award of merit, Hercules, Sam Weller, Greyhound, Eros, Helen Countess of Radnor, Ellen Douglas, Cecilia, Bookham White, Innocence, Mrs. Andrew Brotherhood (very distinct) and Mrs. Robert Gordon were all most charming, and proved conclusively that the world is indebted to this firm for maintaining interest in the beautiful border Carnations that are so much admired.

As usual, Mr. C. Engelmann, Stratton Walden, Essex, set up a noteworthy exhibit. Tall Bamboo stands made a background to many large and small vases in the front, and the exhibit was set up on the ground. The flowers were fresh, clean and of good colour, and their quality was certainly good. Pioneer, Lady Northcliffe, Harlequin, Carola, May Day, Gloriosa, Sunstar, Triumph, White Wonder and Lucy were some of the good things to be seen in this attractive display.

From Mr. Bertie E. Bell, Castel Nursery, Gainsborough, came a most fascinating exhibit of Carnations. They were set up in vases of varying description, and the flowers themselves left nothing to be desired. The quality, colour and freshness were quite good. Notable sorts were Rose Dore, Winsor, Eucrautes, Mrs. C. W. Ward, R. F. Felton, Britannia, White Wonder, Cotillon, Carola and Judith.

That well-known grower, Mr. H. Bennett, Guernsey, had Carnations in grand form and condition. Splendid quality characterised the flowers in the whole of the display, specially good sorts being Mrs. C. F. Raphael, Marmion and La Rayonnante of the Malmison type of this flower. Of the Perpetual-flowering kinds, Mikado, Triumph, Rosette, Mrs. H. Burnett, Shasta, Mrs. Crook, Lady Northcliffe, White Eucrautes and May Day were very beautiful. This exhibit was badly placed, and should have been in the centre of the tent, where the taller vases could have been seen to advantage.

TREES AND SHRUBS.

Mr. L. R. Russell of Richmond arranged a very extensive group at the outside of the large tent. The dominant feature consisted of the specimen Yews for which he is so noted, the large standards of the golden-leaved kinds being particularly attractive. The richest coloured of all was flavescens, though the variety palmata aurea ran it close. Fine specimens of *Hedera dentata variegata* were also very conspicuous. The effectiveness of this group was heightened by the choice low-growing kinds employed as a margin, the variety *Sheen Silver* being one of the very best. Besides this extensive group of evergreens, Mr. Russell had a fine and comprehensive collection of hardy Fuchsias, represented by good flowering plants. The well-known varieties, such as gracilis and corallina, were well shown, and besides these such lesser-known kinds as triodon, brightmeus, Thompsonii, Drame, myrtifolia minor, Eufant Prodiges, globosa and others.

From Messrs. James Veitch and Sons, Chelsea, came a magnificent collection of rare Chinese trees and shrubs. Comparatively few were in flower, but among those in that condition may be especially mentioned the striking *Magnolia delavayi*, *Spiraea Veitchii*, *Viburnum Henryi*, and the golden-flowered *Berberis laevipaniculata*. All the specimens shown were handsome, well-grown plants, and in this way the great decorative value of many of them could be well seen. It is impossible to give anything approaching a list, but the following were especially noteworthy: *Cotoneaster* of different kinds, *Viburnum rhytidophyllum*, *Viburnum Davidi*, *Lindodendron chinense*, *Osmanthus armatus*, *Lonicera pubata*, *Lonicera nitida*, *Berberis Wilsonae*, *Larix Potaninii*, *Acer* in great variety and several *Ymes*. Close by Messrs. Veitch arranged a number of fine specimen *Yags*, some trained as standards and others as pyramids.

Mr. G. Reuthe, Keston, Kent, had, as usual, a large and interesting collection of different plants, among which were many uncommon shrubs. The singular *Rhododendron camelliaeflorum*, with small white flowers like tiny single Camellias, was noted, as also were *Phus parviflora* bearing cones, *Pittosporums* of different kinds, *Fremontia californica* flowering freely, *Psoralea pinnata* with purple Pen-shaped flowers, and several *Rhododendrons* remarkable for their handsome leafage, such as *R. argenteum* of grande, *R. eximium* and *R. Falconeri*.

From Messrs. W. Fromow and Sons, Chiswick, came a grand collection of Japanese *Acer*s, which they grow so well. The arrangement was particularly good, a judicious use of variegated-leaved Bamboos serving to lighten up the purplish tones of many of the Maples. Another notable feature was the way in which comparatively small plants were grouped in large baskets, one variety in each basket. In this way their collective effect could be well noted.

Mr. Carlton-White had a large and varied collection of clipped Box and Yew trees, which, artificial as they are, appeal to many. Some fine standard plants of golden Privet also formed a bright and attractive feature of this exhibit.

Messrs. George Jackman and Son, whose name in the culture of the Clematis is quite a household word, showed a group of well-flowered examples. Of those with large blossoms, which appeal to so many, special mention may be made of Mrs. George Jackman, white; Mrs. Hope, mauve; Rubella, dark purplish red; and Star of India, mauve purple. Small-flowered kinds, whose blossoms are borne in great profusion, were represented by Clematis *Viticellia* alba, white; C. V. kermesina, red; and C. *Flammula* rosea, a pink form of the well-known C. *Flammula*.

Clipped trees were also freely shown by Messrs. William Curbush and Son, Highgate. This firm has for several

years exhibited them freely and done a good deal towards making them popular.

Piney trees were largely shown by Messrs. Barr and Sons, King Street, Covent Garden, the little specimens being all in good health. Many different subjects were represented, but the bulk of the collection consisted of Retinosporas and the Japanese Larch.

The Yokohama Nursery Company, Limited, Craven House, Kingsway, also showed a collection of dwarf trees. These were in many cases grouped together so as to form miniature gardens, with the many strange accessories dear to the Japanese.

FRUIT AND VEGETABLES.

Messrs. James Veitch and Sons, Limited, Chelsea, showed fruit trees in pots of the highest quality and excellence that we have learnt to expect from this long-established firm. The background of the exhibit was filled with well-trained Peach and Nectarine trees, all heavily cropped. Nectarine Lord Napier and Peaches Royal George and Belle's Early being noticeable. The collection comprised Pears, Stovonair du Congo, and Margente Maudslai, Apples James Grieve and Lady Sudeley, both in capital form, Pines Early Transparent Gage, Chillin's Golden, Bonington's Superb, Brandy Gage and Lady Green Gage. Of the most highly-colored fruits, Peaches Penzance and Apple Lady Sudeley were prominent.

The collection of vegetables from the Hon. Vicary Gibbs, Aldenham House, Elstree, was one of the finest we have seen, and did justice to that able gardener and exhibitor Mr. Edwin Beckett. The Cucumbers Ideal, Model and Improved Telegraph were shown in perfect condition, and the same may be said of the fine selection of Tomatoes, including Peach Duke of York, Perfection, Sunrise and Large Yellow. Cauliflowers Foxrunner and Early Emperor, with Cabbage Eliam's Early and Early Heartwell, were neatly arranged in the background. Peas Ours Content and Duke of Albany were perfectly fresh, the pods large and well-filled. Of the root crops the Turnips and Carrots were so regular in outline and uniform that they might have been turned out by machine. The Potatoes Duke of York, Royalty and Monarch were likewise fine. The whole exhibit was admirably staged and of surpassingly high quality.

Messrs. Whitelegg and Page, Chislehurst, Kent, showed the Newberry, a new fruit, the result of crossing the well-known Loganberry and Raspberry superlative. The fruits are unusually large and of Raspberry flavour. Canes many feet in length showed the prolific manner in which the fruit is produced.

Messrs. Stuart Low and Co., Bush Hill Park, Middlesex, had an exhibit of Pigs in pots, all bearing heavy crops. The varieties shown included St. John's, Mansfield's, Brown Turkey and White Ichsa.

A collection of about two dozen Pineapples was sent by Lord Langatock, The Hoe, Monmouth. The fruits were uniform in size and beautifully finished, and reflected credit upon Mr. T. Coulter, the gardener. These fruits are now so little grown in this country that it came as a pleasant surprise to see this fine collection.

From Laxton Brothers, Geddon, came a superb collection of Strawberries. Of the variety shown the following were remarkably fine: Sir J. Paxton, The Bedford, Laxton's Bedford, Champion (of exceptional size and colour), Laxton's Profit, Laxton's Reward, Royal Sovereign, Laxton's Epicure, Mummer, President, Givon's Late Profile and Utility. Two new varieties, namely, The Earl and King George, were shown, the former an improved "Vicomtesse" and the latter a fine early forcing variety, the result of crossing Royal Sovereign with Louis-Gauthier. S. Hedlitt, Esq., The Lodge, Holyport, Maidenhead (gardener, Mr. Camp), sent a number of Pines and Cherry trees in pots, all bearing heavy crops. A large tree of the Black Cherry, Bigarone Noir de Gaben, occupied the centre. Other Cherries that were freely laden were Bigarone Napoleon, Emperor Francis and Bigarone Noir de Schmidt. Of the Pines, Mrs. McLaughlin Gage and Early Transparent Gage were very fine.

SUNDRIES.

Horticultural sundries, as usual, played a very important part at this exhibition. The larger displays were arranged at intervals in the open, and others in the special tent reserved for this purpose.

IN THE TENT.

A large and varied display of the famous Carlton insecticides and fertilisers was staged by Messrs. Walter Voss and Co., Limited, Gleggall Road, Millwall, and some notable examples of seedlings grown with and without partial soil sterilisation by Creol, illustrating the benefit derived from adopting this method.

Messrs. H. Patten and Co., Greyhound Lane, Streatham, had their usual display of horse boots in various sizes, and several useful garden tools on show.

Acme labels, exhibition boxes and all descriptions of wire-trainers and frames required for garden use were prominently displayed by Mr. John Pinches, Crown Buildings, Camberwell, who had a most interesting stand. Messrs. Abbott Brothers, Southall, showed the Osterley table tray, cake stand and honey spoon.

Lawn sand and weed destroyers were arranged by Messrs. A. J. Barbour and Co., Upper Fontaine Street, Leeds.

Many well-known specialties in fertilisers, insecticides, weed-killers, &c., were arranged by Messrs. Joseph Bentley, Limited, Barrow-on-Humber, Hull.

Messrs. Barr and Sons, King Street, Covent Garden, showed a very interesting and varied display of garden requisites, including fertilisers, tools, sprayers, garden labels, bulb planter &c.

Weed-killers, insecticides and fungicides, together with hand-spray pumps, were shown by Messrs. William Cooper and Nephews, Beckenhamstead, in great variety.

A useful selection of garden knives, scissors and trimmers was staged by Mr. A. Canfield, Kenyon, Fulham, S.W.

The Elsenham Jam Company, Elsenham, made a useful display of preserved fruits, jams and lavender water.

French garden requirements of every description were shown by the French Claque Company, Caxton House, Westminster, S.W., who have long made the equipment of French gardens a speciality.

Garden trugs of useful design and light construction were shown by the Garden City Trug Company, Norwich.

Liquid Gishurst compound, fibre, hortite, &c., were staged by Mr. F. Hickson, Anerley Hill, Upper Norwood.

Joyes' Sanitary Compound Company, 61, Cannon Street, E.C., had their stand of well-known horticultural preparations and sprayers.

Mr. A. Key, Norwich, displayed the result of fertilisers on a miniature lawn.

The Lamp Pump, a very cheap and effective means of raising water for gardens and glass-houses, was shown by the Lamp Pump Engineering Company, Carey Street, Westminster, S.W., and should commend itself to anyone requiring an easy means of raising water.

Mushrooms and non-mushroom spawn were shown in a most interesting manner by Messrs. J. Fisher, Limited, Cowley Road, Exbridge.

A motor lawm driven by petrol, which should prove a useful article where large areas have to be dealt with was staged by Mr. C. W. Politt, Gracechurch Street, E.C.

Richest table decorations, in many interesting and varied designs, were shown by Mr. Robert Svedenham, Birmingham, and greatly admired.

Specimens of continuous clothes were arranged to advantage by the Three C's Company, Dale Street, Liverpool, together with useful garden hand-lights.

Mr. C. J. Wakefield, Wilton Road, S.W., had a useful exhibit of "Floral Aids," designed to assist in the economic arrangement of cut flowers.

The well-known garden fertiliser, Hop Manure, was staged by Messrs. Wakeley Brothers and Co., Limited, Boudryas Wharf, Bankside, S.E. This is a most effective and clean manure, which is the only real substitute for stable manure on the market. Garden vases were also shown by the same firm.

Mrs. H. E. Webb, Old-look, Hanwell, showed specimens of bird-nesting boxes and modern feeding appliances.

* * * Owing to pressure on our space we are compelled to hold over the remainder of the report of the Sundries.

OFFICIAL LIST OF AWARDS.

Gold Medal.—The Right Hon. Lord Langatock for Pineapples; Sir Rudolf Baker, Bart., for Sweet Peas; the Hon. Vicary Gibbs (gardener, Mr. E. Beckett) for Vegetables; Messrs. Blackmore and Langdon for Vegetables; Messrs. H. B. May and Sons for exotic Ferns; Messrs. Paul and Sons for Roses; Messrs. William Paul and Son, Waltham Cross, for Roses; Messrs. Sutton and Sons for Orchids; Messrs. Sutton and Sons for Sweet Peas; Messrs. James Veitch and Sons, Limited, for fruit trees in pots; Messrs. James Veitch and Sons, Limited, for Chinese plants; Messrs. E. Wallace and Co. for an ornamental water garden; Messrs. Charlesworth and Co. for Orchids; and Messrs. Dobbin and Co. for Sweet Peas, Cups.

Camaritina Cup.—Messrs. Sander and Sons, St. Albans, for Orchids.

Silver-gilt Cups.—Mr. James Box for a water garden, Sweet Peas, &c.; and Mr. E. R. Russell for stove plants, shrubs and ferns.

Large Silver Cups.—Sir Jeremiah Colman, Bart., for Orchids, Carnations and Roses; Messrs. William Cutbush and Son for herbaceous plants, cut trees and flowering plants; Messrs. G. Bunyard and Co., Limited, for Roses and hardy flowers; and Mr. Charles Turner for Roses.

Silver Cups.—Messrs. Mansell and Hatcher, Limited, for Orchids; Messrs. Stuart Low and Co. for Orchids, Roses, Carnations, New Holland Plants and fruit; Messrs. J. Piper and Son for a formal garden, rock and water plants, Fuchsias, Japanese trees, &c.; Messrs. J. Carter and Co. for a water garden and flowering plants; Messrs. J. Veitch and Sons, Limited, for flowering plants, Bay trees, Orchids, &c.; Messrs. Barr and Sons for flowering and foliage plants, and a herbaceous and water garden; Messrs. W. and J. Brown for Roses and herbaceous plants; Mr. M. Pritchard for herbaceous, alpine and bog plants; and Mr. A. Gwiffin for Begonias and herbaceous plants.

Standard Cups.—Messrs. Stuart Low and Co. for Orchids; Messrs. Peed and Son for Caladiums and flowering plants; Mr. Anos Perry for herbaceous plants, alpinas, Ferns, &c.; Messrs. G. Jackman and Son for Roses, herbaceous plants and Clematis; J. S. Arkwright, Esq., for Lyclins Arkwrightian; and Messrs. W. Froomow and Sons for Japanese Maples.

Silver-gilt Hogg Medal.—S. Hedlitt, Esq. (gardener, Mr. Camp) for fruit trees in pots.

Silver-gilt Knightian Medal.—Messrs. Laxton Brothers for Strawberries.

Silver-gilt Flora Medals.—Mr. S. W. Flory for Orchids; Messrs. J. King and Sons for Sweet Peas; Messrs. G. and A. Clark, Limited, for herbaceous and aquatic plants; Messrs. Baker's for herbaceous and alpine plants; Mr. B. E. Bell for Carnations; Mr. H. Burnett for Carnations; Mr. C. Engelmann for Carnations; Messrs. F. Cant and Co. for Roses; Messrs. B. Cant and Co. for Roses; Hobbes, Limited, for Roses; Wilfred W. Gott, Esq., for Carnations; and Messrs. J. Chel and Sons for an ornamental garden.

Silver-gilt Banksian Medals.—Mr. G. Reuthe for herbaceous and alpine plants and shrubs; Messrs. S. Bide and Sons, Limited, for Sweet Peas; Messrs. E. W. King and Co. for Sweet Peas; Messrs. Gunn and Sons for Phloxes; Messrs. Harkness and Sons for herbaceous plants and Spanish Irises; Mr. G. Prince for Roses; Messrs. Fred Smith and Co. for herbaceous plants and flowers; Messrs. G. Stark and Son for Sweet Peas and Knapfodias; Bees, Limited, for alpinas and hardy plants; the Right Hon. Lord Burnham (gardener, Mr. G. Johnson) for Carnations; John Forbes, Hawick, Limited, for summer-flowering plants; Mr. H. J. Jones for Phlox and Canterbury Bells; Messrs. Thomas S. Ware, Limited, for Begonias; and Mary Countess of Hester for Semper-vivans and Saxifrages.

Silver Flora Medals.—Mr. H. Dixon for Orchids; Messrs. J. Veitch and Sons, Limited, for Orchids; the Rev. Chalmers-Hunt for Rose, Sweet Peas and vegetables; Messrs. Phillips and Taylor for water garden and herbaceous plants; Messrs. Whitelegg and Page for alpinas; Robert Svedenham, Limited, for Sweet Peas; Messrs. R. and G. Cutbush for Humea elegans and Spiraea; Mr. James Douglas for border Carnations; the Guildford Hardy Plant Nursery for herbaceous plants; Mr. T. B. Hayes for Heaths and alpinas; Mr. H. Hensley for Antirrhinums and rock garden; Mr. Mattock for Roses; Mr. Nodent for Roses; Mr. Reginald Pritchard for herbaceous plants; and Mr. Frank Tilley for Gladioli and Sparaxis.

Silver Banksian Medals.—Mr. E. V. Low for Orchids; Mr. James MacDonald for exhibit of Grasses; Mr. Carlton-White for clipped trees; Messrs. Bath, Limited, for Roses and herbaceous plants; Mr. Webster for Sweet Peas; Messrs. Kelway and Son for Delphiniums, Sweet Peas, &c.; Lady Northcliffe (gardener, Mr. J. Goatley) for Chassula coccinea; Messrs. Carter Page and Co. for flowering plants; Messrs. G. Bolton and Son for Roses; Mr. Howard Crane for Violets and Violettas; Mr. Walter Easler for Roses; Mr. Clarence Elliott for alpinas; Messrs. G. Gibson and Co. for herbaceous plants; Mr. G. W. Miller for herbaceous and small plants; Messrs. Morse Brothers for Roses; Mr. W. H. Page for flowering plants; Messrs. Watkins and Simpson for Antirrhinums; Messrs. W. and C. Bull for herbaceous flowers; the Watergrave Plant Farm, Limited, for herbaceous flowers; and Messrs. Godfrey and Son for flowering plants.

Certificate of Appreciation.—Mr. Hensley for work in raising new Antirrhinums.

AWARDS TO HORTICULTURAL SUNDRIES.

Silver-gilt Banksian Medals.—Messrs. T. Crowther and Son for ornamental stone and iron work; and Messrs. Ganuge and Co. for garden tents, &c.

Silver Banksian Medals.—Messrs. Abbott Brothers for Osterley table tray, &c.; Messrs. Banton and Stone, Limited, for spraying machines, &c.; Messrs. Castles for garden furniture; and Messrs. Liberty and Co. for Japanese garden ornaments, &c.

Bronze Banksian Medals.—Messrs. Barr and Sons for tools and implements; Messrs. J. Bentley, Limited, for horticultural elements; Mr. John Bradley for Bunty tea-house; Miss Edith Fisher for water-colour drawings; Four Oaks Spraying Machine Company for spraying machines; Messrs. Hinchman and Co. for ladders, hose, &c.; Mr. Robert Hughes for water-colour drawings; Miss Mitchell for garden baskets; Mr. John Pinches for labels, exhibition boxes, &c.; Messrs. W. Voss and Co., Limited, for insecticides; and Messrs. E. A. White, Limited, for insecticides, sprayers, &c.

AWARDS TO NEW PLANTS.

ORCHID COMMITTEE.

First-class Certificate.—Miltona Sanderla, from Messrs. Sander and Sons, St. Albans; Miltoniada Harwoodii Fowler's variety, from J. G. Fowler, Esq., South Woodford; and Odontodia Brown, from Messrs. Charlesworth and Co., Baywater's Heath.

Awards of Merit.—Cattleya Mossie Dreadnought, from Messrs. Sander and Sons; Odontodia Wilsoni Le President, from Messrs. Charlesworth; Cattleya Senecata, from Messrs. Mansell and Hatcher; and Cattleya Mossie Olympia, from Messrs. Charlesworth and Co.

Fruit and Vegetable Committee.

Cultural Commemoration.—Mushroom Bide's Market, from Messrs. Pitheo, Limited, Exbridge. Awards recommended at Wisley, June 24, and approved by the Council on July 1.

First-class Certificate.—Strawberry Connoisseur, from Messrs. Laxton.

Awards of Merit.—Pea King of the Dwarfs, from Messrs. Sutton; Pea Superb, from Messrs. Laxton, Bedford; and Pea No. 3, 579, from Messrs. Hirst, Houndsditch.

Honour Commended.—Pea Huddlebold (award of merit, 1910), from Messrs. Sutton; and Pea Snowdrop (award of merit, 1908), from Messrs. Carter.

Floral Committee.

First-class Certificate.—Adiantum trapetiforme Queen Mary, from Messrs. May; and Magnolia Delavayi, from Messrs. Veitch.

Awards of Merit.—Adiantum sibirianum and Polypodium Maya cristatum, from Messrs. May; Rose Ophelia, from Messrs. W. Paul, Waltham Cross; Nephthys Lewis Bradbury and N. atropurpurea, from Messrs. J. Veitch; Iris Kampefer Morning Mist, from Messrs. Wallace; border Carnations Virginia and The Baron, from Mr. J. Douglas; Roses Ulster Standard, Maribel Dickson and Mrs. Godfrey Brown, from Messrs. Hugh Dickson, Belfast; and Erigeron hybrida Pink Pearl, from Mr. A. Perry.

TREES AND SHRUBS.

THE WISTARIAS AND HOW TO GROW THEM.

ALTHOUGH the species of *Wistaria* are few in number, they are perhaps the most generally useful of all ornamental woody climbers, for they can be put to many uses and are suitable for planting in many parts of the British Isles. No climber is seen to greater advantage when grown over a pergola than either of the *Wistarias*, the long, pendulous racemes of flowers borne by these plants peculiarly fitting them for the purpose; while they are equally desirable for planting against the walls of houses, on trellises, or against medium-sized trees.

A peculiarity of the various kinds of *Wistarias* is their happy manner of adapting themselves to widely different circumstances. In some cases they are found clothing walls 30 feet high, their branches extending to a length of 100 feet or more, whereas in other instances they appear as quite dwarf, stunted bushes; but in either case they bloom with remarkable freedom. This versatile character is due in a great measure to their partiality for severe pruning, and it has often been noted that after a stunted, spur-like condition of the secondary branches has been produced by constant pruning, the flowers are borne with extraordinary freedom. In this way it is possible to cultivate the *Wistarias* on quite low walls, whereas if they disliked severe pruning it would only be possible to grow them in positions where there was abundance of space. Japanese and Chinese gardeners have taken advantage of their indifference regarding severe pruning, and have for many years grown them as quite dwarf bushes. Examples of this method of culture were prominent at the Royal Horticultural Society's Exhibition at Chelsea, for a group of well-flowered specimens ranging in height from 2 feet or 3 feet to 8 feet or 10 feet was a very noticeable feature. Such plants were also used with effect in the Japanese Garden which was such a popular adjunct to the Japan-British Exhibition a few years ago.

During the last ten or twelve years bush *Wistarias* have been extensively used for forcing for greenhouse decoration in spring, and for that work they possess a quality which is shared by very few other kinds of shrubs, viz., that they may be grown in the same pots for a number of years without serious signs of deterioration and continue to bloom regularly.

Bush *Wistarias* are sometimes used with effect as lawn plants, where, even if they are not kept rigidly spurred back, very ornamental groups may be formed by placing a number of Oak posts or iron rods 10 feet or 12 feet high in the ground and connecting them with cross-bars. The shoots are then trained over the supports and the side shoots spurred in.

When planted against a wall, it is always an advantage if an arrangement can be made so that the branches stand clear of the wall. This may be accomplished by encouraging a spurred system of

growth on the secondary branches, or, where a verandah occurs, the main branches may be trained along the edge. Thus arranged, the inflorescences hang quite clear of the wall and produce a similar effect to that depicted in the accompanying illustration.

The Best Soil. The *Wistarias* make most satisfactory progress when planted in well-drained, loamy soil. They may be propagated by laying the branches in spring or by grafting upon sections of root. Care must be taken during the early stages of growth to prevent the shoots becoming twisted together, for, once they become badly entangled, it is almost impossible to separate them without injury. Train a sufficient number of branches into position to cover the available space; then check the remaining branches.

How and When to Prune. The first pruning may be carried out early in July, cutting the secondary branches back to within three or four

a year or two ago a few miles out of Exeter. There the station-master's house, waiting-rooms, and other offices on a country station were quite covered with this plant in full flower.

***W. multijuga*.**—This also is a Chinese plant, but it has been grown by Japanese gardeners for a very long period, and is the plant which is so popular with Japanese and Chinese artists, its racemes frequently being depicted on screens and pottery. The accompanying illustration of a plant of this species growing upon the residence of Mrs. Godfrey Pearse at Taplow, Bucks, is sufficient evidence of its ornamental character. Its great difference from *W. chinensis* lies in the fact of its inflorescences being very much longer. As a rule, they are anything between 2 feet and 4 feet in length. When grown on a pergola, the full beauty of the inflorescences is apparent. The type has somewhat deeper-coloured flowers than *W. chinensis*, but

A BEAUTIFUL PLANT OF *WISTARIA MULTIJUGA* IN MRS. GODFREY PEARSE'S GARDEN AT HITCHAM LAND, TAPLOW, BUCKS.

leaves of the base. In September, shoots which have appeared during the interval may be pruned back also. *Wistarias* are long-lived plants, and there are numerous specimens in the country which are upwards of fifty years old.

Wistaria chinensis is the commonest and most widely-grown species. A native of China, it is said to have been originally brought to England by Captain Robert Welbank in May, 1816. The plant is too well known to need a lengthy description, for its pinnate leaves and pendulous racemes, 8 inches to 10 inches long, of fragrant, mauve flowers are well known to everyone. Its white variety is also an excellent plant, but *flore pleno*, a form with double flowers, is less desirable than the type. There is also a form with variegated leaves, which is of no special interest. Throughout the country numerous very large plants are to be met with, but one of the most effective displays the writer has seen was noted

there are forms with purplish and white blossoms. Of these the white-flowered variety is the best, and few more beautiful objects can be imagined than a well-flowered group. The racemes are shorter than those of the type, but are from 1 foot to 2 feet long.

W. frutescens is a species from the United States. Its leaves are 9 inches or more long, and the lilac purple flowers appear in racemes from 4 inches to 8 inches in length. It was introduced about 1724, and blossoms later than the Chinese plants. The variety *flore albo* has white flowers; *albo lilacina*, pale lilac blossoms; and *purpurea* and *magnifica*, purplish flowers.

W. brachybotrys, a native of Japan, is a weaker-growing plant than the others. Its bluish or mauve coloured flowers are borne in short, rather dense racemes later than those of the better-known species. White and rose coloured varieties of this species may be obtained. W. D.

THE ROSE GARDEN.

SOME NEW AND LITTLE-KNOWN RAMBLER ROSES.

AS novelties of these delightful Roses appear annually in large numbers, one is sensible of a great desire for a more extended garden, so that space could be found for them. One hesitates to discard old friends, and yet how can we have the newer varieties? It is fortunate for many of us that it is not essential to grow these Roses solely upon arches. They appear equally as charming grown as pillars, or even as isolated bushes. In my rambles through large gardens, I frequently see many positions unoccupied where I should plant them. Given good, prepared holes some 3 feet in depth and 2 feet in width, they thrive admirably. I have numbers of them so growing, each about six feet apart,

the Hybrid Tea *Simplicity* in size, and with charming, glossy foliage. It must be grown by all who admire single Roses; and who does not?

Francois Juranville, although not exactly new, is one of the loveliest and most effective. The buds are so freely produced, and the rich rose colouring of bud and open bloom combine to make a grand display. It flowers in early June, and is seen to the best advantage as a pillar or weeping standard.

Aviateur Bleriot is as yet the richest orange yellow we have, superior to *Shower of Gold* and *Klondyke* in colour, although it is rather wanting in form. Yet in the mass its orange-coloured buds are very charming, and it deserves to be widely grown.

Alexandre Girault is a colour most unique in the wickuraiana class, a deep carmine with rich orange yellow at the base.

Mrs. M. H. Walsh, Lady Blanche and Sander's White are all really good. I have not yet been

shapely of all and quite charming, as beautiful as a Tea Rose.

These, then, are a few of the best of recent introductions. At present we are deficient in good yellows that maintain their bud colour. Even *Shower of Gold* will change to nearly white. I want to see a golden yellow *Dorothy Perkins*. Who will be the fortunate raiser of it?

ROSE BEAUTE DE LYON.

How can one describe the colour of this glorious Rose! The raiser, M. Pernet-Ducher, describes it as coral red, slightly shaded with yellow. I can even detect more shades in its glorious blooms than the raiser has done, for in the blooms before me there is a rich orange shading, with just a dash of pinkish rose on the outer petals. When fully expanded the effect is remarkable. How I wish it were perpetual. It belongs to that group of *Pernetiana* Roses more nearly resembling *Soleil d'Or* in habit, lusty growths with huge prickles and foliage of a lovely bright green colour; but there is no perpetual blooming in the strict meaning of the term, although we obtain a few blooms throughout the summer and autumn. The Rose has the habit of producing its blooms on short stems all the way up a growth, and the top buds open first, although fast followed by the others, thus making from one plant a feast of colour much wanting in our gardens.

Beauté de Lyon opens early. With me it was in full bloom by the end of May, and I could cut hundreds of the charming flowers on any one morning. I am not surprised the French people are asking much for this Rose, and I predict that it will be very popular in our own country for planting in bold beds well isolated, just as one should plant that other delightful early bloomer *Conrad F. Meyer* and its white sport *Nova Zembla*; in fact, the trio would make a most lovely group of themselves. *Beauté de Lyon* makes a superb standard, and it is almost impossible to imagine the effect of a five year old tree well tied out so as to make a spreading head. I should say it is from this Rose or its parents that we owe the wonderful colour in

Mme. Edonard Herriot, the most sensational Rose of modern days. DANECROFT.

ROSA SINICA ANEMONE.

This beautiful single Rose, with silvery pink blooms and bright, shiny foliage, is flowering with unusual freedom this year at *Clandon Park* in Surrey, where it thrives amazingly on a high wall facing due south. The fine example illustrated on this page was planted about eight years ago, and at the present time it has not only exceeded the height of the 12-foot wall, but it covers a space 32 feet in length. It is growing in a well-prepared border of good sandy loam, and receives no special treatment beyond the cutting away of weak and dead wood in winter. Not only is this Rose suitable for a south wall, but for clothing tree stumps in a sheltered position it is invaluable. This variety is sometimes referred to as the *Cherokee Rose*, but it is not the only Rose that lays claim to this title.

ROSA SINICA ANEMONE ON A SOUTH WALL IN A SURREY GARDEN.

and they are never wanting in charm, even when bloom has ceased. A delightful new variety is

Grafin Marie Henriette Chotek, obtained by crossing the *Farquhar* Rose with *Richmond*, and it has inherited a lot of the colour of *Richmond*. With me plants budded last summer are now (June 12) a mass of bloom, the blooms being very shapely and produced in large bunches. It cannot fail to be one of our most useful ramblers. This Rose must not be confused with another named *Grafin Chotek*. Another lovely variety is

Fraulein Octavia Hesse. It is a wickuraiana with all the beautiful glossy appearance in foliage of *Alberic Barbier*, but with a larger and more refined bloom, quite waxy in texture, and of the palest creamy white. This Rose, I believe, will become as great a favourite as *Alberic Barbier*. It flowers about mid-June. A variety that has pleased me much is

Silver Moon, which hails from America. It has immense single creamy white blossoms, resembling

able to compare them to ascertain which is best, but I rather fancy the first named will prove to be the finest trusses. All three are pure white, so that *White Dorothy* will soon have to take a lower position.

Eisenach and Sodenia are good rich colours, the former having single blooms and the latter double, and both will be very welcome.

Sylvia will certainly be wanted in every garden. It yields huge clusters of lemon white, double flowers, is very fragrant and perpetual flowering, and a true wickuraiana in habit.

Ethel is a very dainty variety, yielding quantities of flesh pink blooms, which are gracefully borne upon the plant.

Coronation, with its flakes of white on a scarlet ground, is most showy, and as it comes earlier than *Excelsa*, should prove very valuable.

Joseph Liger has very double flowers of a pale canary colour, tinted pink. It is one of the most

GARDENING FOR BEGINNERS.

HOW AND WHEN TO BUD ROSES.

THE budding of Roses upon various stocks is simplicity itself as an operation, but somewhat difficult to describe. A few minutes spent in closely watching a skilled hand will go much further than the most elaborate paper upon the subject. This is why I have appended

of bark that is generally removed with the bud (see Fig. 2a). This facilitates the removal of the Rose wood (Fig. 2b). Now, if the seat or heel of the bud is prominent and in such a condition as to permit of its lying close upon the exposed wood of the stock, which we shall presently come to, it is fit for use. Should the Rose eye or bud be too forward or the reverse, the root or seat of the bud will tear out and leave a small hollow when the small portion of Rose wood is removed. Such a bud is absolutely useless. The leaves should be cut off, as in Fig. 1b, directly the shoot is removed from the parent Rose, otherwise there is much loss of sap, which dries up the bud and prevents the clean removal of the undesired portion of Rose wood. Always keep the Rose buds moist, but not over-wet, at the seat when extracted and prepared for insertion.

able to discover whether your operation is a success or a failure; in the latter case the buds will have turned black, and the same stock or shoulder can generally be tried again a little beyond the first attempt. So long as one does not let the Rose bud get dried up, I have found fine weather more successful for the operation than showery weather, and it is never advisable to have water in the wound made to receive the bud. Have a sharp and clean knife, do the work with as little force and banging as possible, and you should be successful in the majority of cases. As a rule, we do not interfere with the growth of the stock until the winter or early spring after budding, but a few of any straggling growths may be cut away after the bud is well set. A. P.

PREPARING BUDS FOR INSERTION.

Inserting the Bud.—In Fig. 3a we find a shoulder of a standard Briar which has had a cut about two and a-half inches long made lengthwise in the bark. This should never be more than just through the bark, any injury to the wood beneath being greatly against a successful "take," and often quite fatal to the survival of the Rose bud. Lift or prise up the bark carefully with a thin piece of ivory or metal, generally found at the end of a handle of a budding-knife. If you do not possess such a knife, a piece of hard and thinly-shaven wood may be used. Avoid, as far as possible, any disturbance of the glutinous sap lying between the bark of the stock and its wood. The Rose bud (Fig. 2) should be cut off at the dotted lines, and then gently inserted beneath the sides of the raised bark, as depicted in Fig. 3b. Slip the bud well down to the bottom of the cut and close to the main stem of the standard stem. In Fig. 4 we have a dwarf stock with the bud inserted, which should be as near to the ground-line and base of the stock—in fact, upon the crown of roots—as possible. It only remains to tie in firmly, without constriction, as in Fig. 3c, taking great care to have the seat of the bud firmly upon the wood of the stock.

LAYERING THYME.

From a few clumps of old plants a splendid batch of young ones may soon be obtained by judicious layering. The tendency of old plants is to produce a number of long, bare stems with young branches and leaves at the extremities. When these stems are layered with plenty of roots formed on them near the base of the young shoots, many quite bushy plants are the result. Mix together loam, leaf-soil, sand, road grit or old potting soils, and, having carefully spread out the clump of Thyme, place a shovelful of the compost in the centre. Then with one hand lift up the fringe of growing Thyme, and put some compost underneath with the other. Finish the work by putting more soil in the centre and pressing it down firmly. All that it is necessary to do now is to keep birds away and the new compost in a consistent state of moisture. When sufficiently rooted, the layers must be cut away from the parent plants and planted 18 inches apart in a new bed. This distance will allow them room to grow in without overcrowding. AVON.

a few rough sketches to help those who have not the opportunity of a practical lesson.

Budding is one of the most important points towards successful Rose-growing, and is the main method of propagating. July and August are the most suitable months for the operation, but no set time can be given, seeing so much—in fact, all—depends upon having both Rose bud and the stock in a suitable condition for the work.

In the illustrations I have dealt with stocks intended for standards, which are usually tall Briar stems collected from the hedgerows. But I may say at once that the budding of dwarfs is upon the same principle, and that, whatever the stock may be, it is essential to work the Rose buds as closely to the base of dwarfs on the one hand, or the main stem of standards on the other, as can be managed.

Selection and Preparation of the Buds.—It is of vital importance that the bud should be in the right condition, *i.e.*, about half ripened. A good general guide to this state is the easy snapping off of the Rose thorns. Buds from below an expanded flower, or where one has been cut from, are generally fit. But the real proof of fitness lies in the way the small piece of Rose wood can be removed from the bud after it has been cut away from the shoot of growth, as shown in Fig. 1a. In the sketch I do not show the longer string

So far as the budding of dwarf stocks is concerned, it is advisable to draw soil around these for a few weeks previous to operating. This conduces to a softer condition of the bark and easier lifting of the same. Should the bark be in the least obstinate when lifting, do not upon any account force it, but water well and try again a week or so later, for the whole of the operation must go smoothly and quickly, without any semblance of force or bruising. You will find, too, that any cutting away of superfluous growth upon the stocks will cause a check of sap that will make the bark cling for about a week, so do not interfere with the growth just previous to or at the time of budding.

After-treatment.—When the bud is set, which will be in two to three weeks, keep a look-out for any undue constriction caused by the swelling of the stock. Sometimes this is very rapid, in which case the tie must be slightly loosened, if not entirely released. Raffia is about the best and cheapest tying material, and can be readily freed by cutting through with the point of a knife on the side opposite to the Rose bud. Take care only to cut through the tying material; any cutting of the bark will only mean a widening gap that takes time and sap to heal over. By three weeks, also, you should be

METHOD OF BUDDING ON THE SHOULDER OF A STANDARD BRIAR.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Flower-Beds.—Now that the plants in the beds are nicely established, less watering will be needed. The Fuchsias and a few other free-growing subjects must not be neglected. Ivy-leaved Pelargoniums, Fuchsias, Ricinus, Perillas, Melianthus and other quick-growing plants must be staked and tied as they require it, or the first heavy storm of wind and rain may do considerable damage.

Liliums and Gladioli that are throwing up their flower-stems must also be attended to, whether they are planted in borders or beds. Stake in as unobtrusive a manner as possible. One or two good soakings of liquid manure (not too strong) while the plants are growing will add materially to the quality of the bloom.

Narcissi and Darwin Tulips planted in beds for cutting purposes should now have ripened off sufficiently to warrant their being lifted. Dry weather is the best time to choose for this purpose, and, after lifting, the bulbs should be exposed to the air and wind for a few days to become perfectly dry, when they may be stored away in a dry, airy shed, preferably in trays similar to those used for seed Potatoes. Here they may remain till the time for planting.

Wallflowers.—Early-sown plants will soon be forward enough for planting out, although if the weather happens to be dry it is best to leave them till there is a likelihood of one or two days' rain or dull weather. Keep the hoe going between the rows in the seed-bed, and this advice is applicable in all cases where seedlings are being raised.

Myosotis.—Choose a day after rain to get this seed in, sowing it broadcast on a light piece of ground which has been nicely broken up and levelled. Though not difficult to raise, much seed is often wasted by burying it too deeply, and I prefer only to beat it into the soil with the back of a rake. There are many varieties used for bedding, but Royal Blue is perhaps the best for the purpose.

Plants Under Glass.

Layering Malmaisons.—Early-flowered plants will now be ready for layering. Good, healthy shoots only should be layered, and when the plants have too many shoots to allow of plenty of room between the layers, they should be reduced, or as the young plants make root they will become attenuated; also, there is more difficulty in preserving the roots when lifting. Lightly syringe in the morning and afternoon, giving a little shade during the hottest part of the day; this will keep the foliage in a good, healthy condition till the layers make root. Later batches may be layered as they go out of bloom; but it is imperative, to obtain good plants for early blooming, to get a batch layered as early as possible.

Perpetual-Flowering Carnations.—Plants nicely rooted in the flowering pots and intended for autumn blooming should now be gone over and stopped for the last time. Plants that may have been propagated late to increase the stock of newer varieties should be given their final potting at once; these, if stopped towards the end of the month, will come in for midwinter and early spring blooming. Syringe frequently to keep the plants clean, and spray regularly with an insecticide to keep the tips free from fly. Though the plants may take a fair quantity of water just now, over-watering is the worst possible thing for them, for though big, leathery-looking foliage may look well, it is not at all an essential for good quality flowers, and is certainly more liable to attacks of rust.

Stove and Greenhouse Climbers must be kept regularly tied, and plants such as Bougainvilleas and Allamandas coming into flower should be kept well watered and fed.

Propagation.—Small decorative subjects, such as Panicum, Selaginellas, Tradescantias and Fittomas, should be propagated regularly, these being very useful for surfacing large pots in the dwelling-house and as edging plants in the houses.

The Kitchen Garden.

Sweet Corn.—Plants of this should be growing freely if the weather keeps warm, and liberal waterings should be given; this will induce the cobs to

swell up quickly. If grown slowly they are apt to become tough or hard before the cobs attain edible size.

Marrows and Gourds also are making rapid growth; in each instance they must be liberally supplied with water and manure. The Marrows should be cut in a young state, and not allowed to remain on the plants till they get old, or the further fruiting properties will be impaired. Gourds that are being trained up poles or pergolas must be regularly tied, and thinned if necessary, using a fairly strong, soft string for the purpose. This is especially necessary where the plants produce heavy fruits.

Leeks.—The earliest plants may have a little soil drawn up to them, but it is not advisable to cover them up too much at once; also provision must be made to keep the roots supplied with water, as they take a great deal of moisture out of the soil, without which it is impossible to obtain good results.

Onions.—This is a crop which pays for a little extra attention, and during dry weather the bulbs should be watered and fed fairly liberally; but the autumn-sown bulbs may not require much after this date, as they will soon begin to mature, and too much water sometimes induces them to split.

Fruits Under Glass.

Successional and Late Peaches must be kept regularly tied, and where these are coming on too fast, a little whitening or some other shading may be put on the glass, and so steady them somewhat. This shading is also an advantage in the case of Nectarines, some varieties being rather apt to burn slightly during a very hot spell, though to get a really good colour in the Peaches they must be exposed as much as possible to the light.

Hardy Fruit.

Peaches.—Early varieties, such as Annsden June and Hale's Early, are now swelling freely, and to ensure good flavour and texture in the fruit, liberal supplies of water and manure should be given, keeping the trees syringed daily, at least during hot weather. Keep all shoots tied or nailed in regularly, and expose the fruits as much as possible to light and air—in fact, treat them as though they were under glass—and in a favourable situation the fruits will be nearly as good in quality, if not so delicate in appearance, as those under cover.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Staking Annuals.—Where they are rather closely surrounded by high trees, some of the taller annuals, such as the Stock-flowered Larkspurs and Scabious, will be all the better for staking and tying, as a high wind might do much damage were this attention omitted.

Dahlias.—These are now growing freely and require close attention in the matter of tying, as their succulent stems are easily broken. At the risk of being charged with reiteration, I must again recommend binder twine, as for all strong-growing plants of a herbaceous nature it is so much superior to tarred twine or raffia, as it combines strength with softness. Where old tubers were planted, the growths will require thinning out.

Hoing.—This work should have frequent attention. Plants refuse to thrive where the surface of the soil is allowed to become baked and hard; moreover, weeds at this season are persistent unless kept in check.

The Rose Garden.

Taking Notes.—July is the Rose month in the North, and is the best time for taking notes for future use. Special attention should be given to new introductions, noting their merits and defects, bearing in mind that a variety should not be condemned on one year's experience unless it has some obvious radical defect.

Feeding Teas.—In order to secure a good autumn crop of bloom, the Teas should have a little feeding. A light dressing with Thomson's Plant Manure will do all that is wanted. Run the hoe

through the bed or border after applying the fertiliser.

The Rock Garden.

Propagating Phloxes.—The alpine Phloxes form one of the most valuable assets the owner of a rock garden possesses. In the subulata section there is great choice, from the pure white of Stellaria and The Bride to the deep rose of Daisy Hill and Vivid. Among other species, *anacena*, *canadensis*, *alba*, *c.* *Lapham* and *ovata* all have much to recommend them. Cuttings of any of the foregoing may be put in from now till the beginning of September. Five-inch pots filled with sandy loam and surfaced with clean sand will be found suitable. Place in a shaded frame, such as that recommended for Pinks and Cheiranthus.

The Wild Garden.

Funkias.—I am more deeply impressed than ever with the beauty of the Funkias, especially *subcordata* and *undulata* *folis* *variegata*. Dig a pit in the grass, 18 inches wide and the same depth, fill it with rich soil, plant a strong clump of either of the above in it, keep the grass mown round it, and in due time it will prove an object of great beauty.

Oreocome Candollei.—This is another graceful plant, with finely-cut, Fern-like foliage. It should be planted as recommended for Funkias. Rabbits are fond of its tender foliage, but if the garden is not rabbit-proof, a circle of dwarf wire-netting should be placed over the plant in the early part of the season.

Plants Under Glass.

Perpetual Carnations.—Where it is intended to grow on last season's plants which have finished flowering, the old flower-stems should be cut well back. Some of the surface soil should then be carefully removed, and the plants should receive a top-dressing of, say, two parts loam, one part old Mushroom manure, with a good dash of bone-meal and wood-ashes. Syringing in the morning and evening in hot weather will prove highly beneficial to the whole stock.

Top-dressing Calanthes.—The deciduous Calanthes are gross feeders, and will be much benefited by receiving a top-dressing of old cow-manure about this time.

Fruits Under Glass.

Vines.—In houses where the crop is ripe, dry conditions must obtain. In houses where the fruit is beginning to ripen, the border should be examined, and if there is any tendency to dryness, it should receive a good watering, as water must not again be applied until the crop is cut. This precaution and the sprinkling of the pathways daily for some weeks yet will do much to check the attacks of red spider.

Figs: Second Crop.—Where Figs were ripened early, a good second crop may be expected on the current year's wood. After from four to six fruits have been formed, the point of the shoot should be pinched out, in order to throw the vigour of the tree into the swelling fruits.

The Hardy Fruit Garden.

Loganberries.—Continue to train the young shoots as growth advances, and remove all superfluous shoots. Make sure that the crop is protected from the birds.

The Vegetable Garden.

Staking Late Peas.—This work must receive attention. If stakes are scarce, the last sowing may have a few twigs supplied to the plants to carry them on till the pods from the first sowing have been picked, when the stakes from it can be used again.

Broccoli.—The planting of this crop should be finished as soon as possible and any blanks in those previously planted be filled up.

Vegetable Marrows.—Watch for the appearance of female blossoms and duly pollinate them, as one cannot always depend upon this being done by natural processes. Thin out the shoots before those which are superfluous rob those that are to remain.

Turnips.—Thin succession crops and make another sowing of Early Milan for autumn use.

Salading.—This requires constant attention. Mustard and Cress should be sown weekly, Radishes fortnightly, and Lettuces every three weeks or so.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Mulloitham.

THE UPKEEP OF LAWNS.

AS a constant reader of THE GARDEN, I see from time to time a good many articles and replies to correspondents upon this subject. Most of them are admirable, but there are one or two points upon which I venture to differ. I am old-fashioned enough to think that, at my rate upon strong soil, it is rather a mistake to destroy all the worms, for I think that they are useful in draining and aerating the soil, and also that they improve the soil. One of your correspondents suggests that they only bring up good soil to the surface which had better have been left where it was, but I take it that a certain amount of soil which passes through the worms is by this operation transformed from what was often poor subsoil into a valuable mulch for the roots of the grasses. Of course, golfers will have greens free from worm-casts, and I am not so sure about the value of worms on lighter soils; but I think it is a mistake to destroy them in lawns which are formed upon clay soil. Incidentally, I hear that in consequence of the increased use of worm-destroyers in and around London, a very large number of thrushes have been poisoned, and that this fine songster is in danger of being exterminated, leaving the less welcome blackbird to take his place.

Then as to top-dressing lawns, I see decayed manure, soil, &c., recommended to be applied in thicknesses varying from a quarter of an inch to an inch! I wonder if the writer ever dressed a lawn to the depth of an inch. He would, I think, be surprised at the quantity of soil which would be required, and I should be surprised if many of the finer grasses in the lawn ever survived the treatment. One very frequently sees superphosphate of lime recommended for lawns; but if you do not wish to have your lawn a mass of white Clover, you must not apply superphosphate.

Sometimes the what-not-to-dos are as instructive as the what-to-dos; but lest I should be told it is more easy to criticise than to advise, I will say that on strong soil I give my tennis lawns a dressing of sand every winter, two cartloads to each lawn, spreading this as evenly as possible. In the early spring this is swept perfectly level and practically disappears, but it improves the grass and helps to make a firmer foothold for the tennis player. A little later in the spring about half a hundred-weight of chemical manure (anti-Clover) is applied, which dressing is repeated in the autumn—the end of September, or October, according to the weather; this washes in with the first shower. For brushing in the sand we use a homely branch of an Elm sucker about eight feet or nine feet long, and we sweep the lawns with this to spread worm-casts in the early part of the season (of course, an extra long Birch broom would be equally effective). We do not roll much after March, and we never mow without the grass-box, for I think the grass cuttings, if left on the lawn for a mulch, do more harm than good, as fine grasses do not like much mulching. I almost ruined a lawn by mulching with stable manure one season, for the manure killed most of the finer grasses and encouraged the coarser ones.

Then as to weeds. Everyone who cares for a good lawn knows what a trouble they are, especially on new lawns and impoverished old ones. Some grumble at the cost of lawn sand, which is very effective if used properly; and more of us who are not quite so young as we were grumble at the backache which ensues from applying lawn sand

a pinch at a time. For this class I have a fine remedy. I bought the other day a thing called Kilm, a tube containing some chemically-treated sand with a spike at the end of the tube; this one presses into the crown of a Plantain, Dandelion, or the root of a Buttercup, and a small quantity of the sand is released, which falls on the plant and burns it up. Having been idle through a sprained knee, I have found great delight in hobbling round my lawns and destroying a few weeds, for the lawns are not yet perfect, though I think Kilm is a perfect cure for weeds and backache, and I am sure that any lady gardener will be pleased with it. N.B.—Care must be used, as it is poisonous.

Loedham.

A. H. PEARSON.

THE KITCHEN GARDEN.

WHEN AND HOW TO GROW ENDIVE.

CULTIVATORS who have had some considerable experience with this valuable plant know how very important it is that more than one sowing of seeds should be made. In some seasons, sowings made on certain corresponding dates each year do not yield satisfactory crops of plants. In one year the latter may grow and form grand hearts; in another, they will prematurely bolt, or run to seed, and be quite useless. This will happen in the same district. Of course, seeds must be sown about ten days earlier in northern counties than in southern ones. In both cases it is advisable to make two sowings, the second about a fortnight after the first. If the resultant plants from the first sowing are too early, those from the second may be quite satisfactory.

Sow Broadcast Thinly.—A cool border should be selected on which to form the seed bed. Ground previously cropped with early Potatoes is generally the most suitable for both raising seedlings in and for the plants when finally put out. It will, in such cases, not be at all necessary to dig or manure the soil; simply fork it up and break the large lumps; then tread it down if of a light nature, but do not tread if it be of a heavy, retentive nature. Rake the surface with a wooden rake, finally drawing the rake in one direction. Sow the seeds broadcast and very thinly; some of them will fall into the shallow furrows left by the rake; then lightly draw the same tool across in the opposite direction, and the seeds will be sufficiently covered.

Transplanting the Seedlings.—In the meantime a larger bed must be prepared, in which the sturdiest of the seedlings should be transplanted, at a distance of 4 inches apart each way. Firmness, again, in the case of light soils, is essential.

The Final Planting.—Where the cultivator can command several positions in his garden he should put out plants in each, and not confine them to one. In every instance the plantations made should be compact, so that it will be convenient to cover the plants during frosty weather. Many are lifted by cultivators and placed in cool frames in low-lying districts, to prevent injury by frosts and excessive moisture, but as such accommodation cannot be found for all the plants, some covering material must be put on. When covered for blanching purposes the leaves must be perfectly dry, else the heart portion will decay.

Avon

ANSWERS

TO CORRESPONDENTS.

RULES FOR JUDGING (T. T.).—The Royal Horticultural Society, Vincent Square, London, S.W., issues a code of judging rules, and this is doubtless the book to which you allude. It is procurable from the address given for 1s. 6d., post free, to judges, exhibitors, committees and officials. It is a publication of the utmost value, which cannot be too diligently studied.

LAWN CLIPPINGS (L. K.).—Lawn clippings decayed are useful manure, but on a heavy clay soil they are liable to add to the amount of water held, and render the soil wetter and colder. They would be less bad if added comparatively fresh, provided lime is present in the soil. A strong brine may be used for the purpose of killing weeds, and it is innocuous to domestic animals.

TROUBLESOME WEEVILS (F. T.).—The insect had disappeared from the box, but from your description we suspect it is a beetle called the Vine weevil or the clay-coloured weevil. Your best plan would be to spread a sheet under the affected plant and shake off the beetles after dark, or cause them to fall by slipping a bright light upon them. The larvae are extremely troublesome to roots of Ferns, Pelargoniums and other greenhouse plants, and it would be avoiding much danger of this kind to catch and kill the beetles now. The latter may be done quite easily by dropping them into a pail containing a little paraffin.

WOODLICE IN GARDEN (E. M. C.).—It is unusual for this pest to do much mischief in the garden, unless encouraged by rubbish or decaying woody stuff lying about. However, as the insects appear to have done some mischief, you had better place dry boards, slates or even small pieces of sacking, with cut strips of Potato, Carrot or such-like things beneath, for them to feed on. Examine these retreats nightly, and with the assistance of a kettle of boiling water you may dispose of large numbers. These things often harbour in the vicinity of garden frames, and if you have any such, lay other traps near them. This pest in large numbers is very destructive to all vegetable life, and increases with great rapidity. Both the hedgehog and the toad will devour large numbers, and in the greenhouse more particularly we encourage the latter for its servability in this direction.

ERADICATING BISHOP'S WEED (A. P. F. P.).—The only sure way of eradicating this pest is by forking it out and burning it. No weed-killer could possibly reach it, owing to the underground spread of its roots, or, if it killed it, the roots of plants near would suffer in like degree. When digging cannot be done, the sufferer might be much weakened by plucking off every sign of leaf growth, and though the operation is a tedious one, some of the most insidious of the weed pests of the garden have been killed in this way. This, indeed, is the only method we know of impairing the vitality of the plant when the roots have been entangled with shrub roots. In autumn such plants could be lifted, washed clear of all soil, and the weed picked out. As every scrap, even to that of half an inch long, is capable of making a plant, nothing short of the most drastic methods, accompanied by much perseverance, are calculated to effect a clearance.

TACSONIA BUDS DROPPING (H. B.).—The Tacsonia, like some other climbers, is liable to drop its buds if it has unlimited root room, even if there is a prepared border for the reception of the roots. They will often run away therefrom into unsuitable soil, and then the buds sometimes drop. The same result might ensue if the roots were in a confined space and allowed to suffer from the want of water. If the plant is cut back hard every year, it would lead to the production of strong, soft shoots, from which few flowers could be anticipated. The greatest measure of success in flowering the Tacsonia is in the autumn to thin out any old or weakly shoots, especially where they are entangled into a close mass. This will allow of the ripening of the wood under the influence of light and sunshine. If the plant has covered its allotted space, the more vigorous shoots may be shortened back to keep it within bounds; if not, they may be allowed to remain entire. Providing the plant is in good condition, young shoots will in the spring be freely produced, and in the ordinary course of events they should flower well.

NAMES OF PLANTS.—M. A. B.—Rose Charles Lawson, a Hybrid Chinese. The Pink, though charming, is not a named variety.—*H. Upton*.—Callirote lineariloba. The Lupine appears to be a pretty seedling form of Lupinus polyphyllus, and is well worth growing.—*E. M., Parkstone*.—The Carnations are: 1, Rose Doré; 2, May Day; 3, Dufrance; 4, Britannia.—*Adela Box*.—We believe it to be the old Noisette, Solfaterra.—*Fred Hobbs*.—Carpenteria californica.—*W. J. H., High Wycombe*.—Saxifraga trienspidata and Oxycaria digna.—*Devonian*.—Cichorium Intybus (Chicory) and Brunfelsia calycina.—*Winton*.—1, Potamogeton polyzonifolius; 2, Eriophorum angustifolium; 3, Orchis maculata; 4, Pedicularis palustris; 5, Orosora rotundifolia; 6, Polygala vulgaris; 7, Verbascum phoeniceum variety; 8, V. phlomoides; 9, V. Chaixii.—*Bull, Hereford*.—1, Sedum rosarium; 2, Campanula portenschlagiana; 3, Veronica Tenorium montana; 4, Saxifraga trifurcata; 5, S. hirsuta; 6, Centaurea montana; 7, Heuchera micrantha; 8, Omphalodes verna alba; 9, Campanula latiloba; 10, Veronica virginica; 11, Campanula persicifolia alba; 12, Hemerocallis flava; 13, Pentstemon, garden seedling; 14, No specimen; 15, Pentstemon, garden seedling; 16, Saxifraga cordifolia; 17, Linaria purpurea variety.

SOCIETIES.

CITY OF LONDON ROSE SOCIETY.

The first exhibition held in connection with the above society was opened by the president, the Lord Mayor, at noon on Thursday, the 26th ult. The display of Roses was particularly good, and surpassed even the most sanguine expectations. In the open classes some of the best Rose nurserymen in the United Kingdom contested, but it was the classes for members living within the eight miles radius of the Royal Exchange that proved most interesting, inasmuch as they demonstrated how well the Queen of Flowers can be grown in the vicinity of a great city. Owing to the demand made on our space by so many other shows, we regret that we are only able to publish particulars of the principal classes.

In the nurserymen's section Messrs. Alex. Dickson and Sons of Newtownards were first out of ten entries for forty-eight blooms, distinct, staging some superb examples. Second honours went to Messrs. B. R. Cant and Sons, Old Rose Gardens, Colchester, and Messrs. R. Harkness and Co., Hitchin, were third.

For twelve distinct varieties, three blooms of each competition was equally strong, first honours falling to Messrs. G. and W. H. Burch of Peterborough, who had The Lyon Rose and Mrs. T. Roosevelt in superb condition. The second prize here went to Mr. George Prince, and third to Messrs. Alex. Dickson and Sons, Newtownards.

For eighteen Teas or Noisettes, Mr. G. Prince of Oxford was first with a very clean lot of flowers, his bloom of Molly Sharma Crawford being very fine. Messrs. J. Burrell and Co. were second and Mr. John Matlock third.

For eighteen bunches of decorative Roses, to be staged as naturally as possible, there was good competition, first prize going to Mr. John Matlock, Headington, Oxford, who had a beautifully clean lot of flowers, Duchess of Wellington and A. R. Goodwin being conspicuous. Messrs. William Spooner and Sons of Woking were second, having Mrs. Alfred Tate in fine form. The third position was filled by Messrs. Frank Cant and Co.

Class 5, for seven baskets of cut Roses, was well contested, Messrs. Chaplin Brothers of Waltham Cross being first with good Lady Hillingdon and General Macarthur. Second prize went to Messrs. Alex. Dickson and Sons, whose Queen Mary and Irish Fireball were very charming. Mr. A. B. Hammond, Burgess Hill, Sussex, was third. This was a very beautiful class.

For twelve blooms of new Roses, Messrs. Alex. Dickson and Sons were first with the following: Mrs. Amy Hammond, Mrs. G. Preston, Mrs. Foley Hobbs, Edward Hawley, Alexander Hill Gray, Duchess of Sutherland, Mrs. Arthur E. Coxhead, Mabel Drew, Mrs. J. H. Welch, Mrs. H. Hawksworth, Lady Greenall and Lady Barham. The second prize went to Messrs. B. R. Cant and Sons, and third to Messrs. J. Burrell and Co.

In the open amateurs' section competition was good, the challenge cup offered for twenty-four blooms, distinct, being won by William Onslow Times, Esq., Bedford Road, Hitchin, whose flowers were large but rather soiled. Mr. Henry Balfour, Langley Lodge, Headington Hill, Oxford, was second, and E. F. Brown, Esq., Lynton, Sussex Place, Slough, third.

For twelve blooms, distinct, E. F. Brown, Esq., Lynton, Sussex Place, Slough, was first, his Dean Hole being very fine. Courtenay Page, Esq., Broad Street Place, E.C., was second, and E. Jackson, Esq., Rochford, Essex, third.

In the members' classes, the City of London Challenge Cup, for twelve blooms, distinct, went to H. L. Weltern, Esq., 16, Water Lane, E.C., for a superb dozen, the best of which was Yvonne Vacherot, which gained the medal offered for the best bloom in Classes 9 to 17. These Roses were a great credit to the exhibitor. Lewis S. Pawle, Esq., Stock Exchange, was second, and John Hart, Esq., third.

The metropolitan classes, open only to members who grow their Roses within eight miles of the Royal Exchange, were most interesting and well contested. The challenge cup for twelve blooms, distinct, went to E. H. Coxhead, Esq., of Streatham, who had a lovely bloom of William Shrub. The second prize went to R. de Escofet, Esq., Dulwich, whose box contained the best bloom in Classes 24 to 29, this being Mrs. Myles Kennedy. Mr. de Escofet also won the challenge cup offered for nine exhibition Roses, distinct, with a fine lot of flowers.

A. C. Turner, Esq., 29, Great St. Helens, E.C., was the winner of the challenge cup offered for twelve bunches of decorative Roses, distinct, Lady Hillingdon and Gardenia being very fine. The second prize here went to H. L. Weltern, Esq.

The best bowl of cut Roses arranged with Rose foliage was shown by Mrs. A. C. Robinson, this being a delightful arrangement of Rose Mine, Abel Chatenay and foliage of Rosa rubrifolia.

The following Roses were awarded the National Rose Society's silver medals, offered for the best blooms in the show: Classes 1 to 6—H. Hartmann, a new Hybrid Tea of bright scarlet crimson colour, broad, shell-like petals and deep centre, shown by Messrs. B. R. Cant and Sons, Classes 9 to 17—Yvonne Vacherot, shown by H. L. Weltern, Esq. Classes 18 to 23—Avoca, shown by A. E. Stanger, Esq. Classes 24 to 29—Mrs. Myles Kennedy, shown by R. de Escofet, Esq.

ROSES AND SWEET PEAS AT BOURNEMOUTH.

Last year the members of the Bournemouth Gardeners' Mutual Improvement Association held a small show for the purpose of raising funds for the benefit of the association. It was a great success. The competitive classes were open only to the members, but local nurserymen were

cordially invited to stage non-competitive exhibits, and the response was most satisfactory. This year the members amalgamated with the council of the Bournemouth Horticultural Society, and arranged to hold a much larger exhibition and to invite nurserymen from a distance to show. The first date of the two days selected was June 25, "Alexandra Day" proving a very popular choice, as crowds of people visited the show, which was, in every way, most successful. Messrs. Carter, Raynes Park; Messrs. Webb, Stourbridge; Messrs. Dobbie, Edinburgh; Messrs. Keynes, Williams and Co., Salisbury; Messrs. George Cooling and Sons, Bath; J. Stevens, Wimbome, Dorset; and Mr. Maurice Pritchard, Christchurch, were the principal nursery firms exhibiting. The show was held at the Winter Gardens, not in the spacious pavilion, but in tents on the lovely lawn, which is surrounded by stately trees, including Pines, and charming shrubs. In one tent the members of the Bournemouth Gardeners' Association staged their competitive exhibits, and in the large tent the various nursery firms staged theirs.

THE GARDENERS' TENT.

Mr. W. Shave, Wimbome, had the best table decoration of Sweet Peas, Mr. Heath (gardener to G. G. Russel, Esq., Bournemouth) being second. The last-named exhibitor won in the class for a table decoration of Roses; Mr. Evans (gardener to G. J. Fenwick, Esq., Craig Head, Bournemouth) was second. Messrs. Heath, Weaver (gardener to Major Tinker, Christchurch) and Evans won in the order named for a basket of Roses. Messrs. Shave, C. Pearce (gardener to Mrs. Ormond, Bournemouth) and W. E. Wilkins (Bournemouth) had the winning bowls of Roses respectively. Mr. Taylor (gardener to Walter Child Clark, Esq.) won in the class for six vases of Roses, staging grand blooms; he was followed by Messrs. C. Pearce and W. Webb. Mr. Heath had the best espousure of Sweet Peas. Mr. Weaver staged very fine Sweet Peas in the classes for nine and six vases respectively. Messrs. G. Cockman and C. Pearce following in these classes. The display of Sweet Peas on a given space of tabling was a good class, but only two members competed, namely, Messrs. Shave and Weaver, who won in the order named. Mr. C. Humphries staged the best single bloom in the Rose classes, winning with a fine specimen of Hugh Dickson. Walter Child Clark, Esq., had a table of twenty-two vases of Roses, chiefly Lady Waterflow, grown under Pine trees. The blooms were magnificent, and a first-class certificate was awarded, a similar award going to R. Chamberlain, Esq., the chairman of the council, for a table of Roses, Carnations and Sweet Peas. Mr. Weaver had the best three vases of hardy herbaceous flowers.

NON-COMPETITIVE EXHIBITS.

Messrs. Watts and Sons, Limited, were awarded a gold medal for a fine display of Roses and Carnations, beautifully staged; Messrs. Webb and Sons, a gold medal for a grand lot of Sweet Peas, about eight varieties, charmingly staged; Messrs. Carter, Raynes Park, a gold medal for about fifty vases of Sweet Peas of high merit.

Mr. J. Stevenson was given a silver medal for fifty vases of Sweet Peas, arranged in his well-known style, light and graceful; Messrs. Dobbie, a silver medal for fifty vases, beautiful in colour of flower, but cut rather short in the stem; Messrs. Cooling and Sons, a silver medal for lovely vases of climbing and Hybrid Tea Roses; Mr. T. K. Ingram, a silver medal for standard Roses and Liliums; a similar award to Mr. M. Pritchard for a grand collection of hardy herbaceous flowers.

Certificates were awarded as follows: Messrs. Keynes, Williams and Co., for Roses; Mr. H. M. Elford, for border Carnations on plants and boards; The Burton Hardy Plant Nursery; Mr. D. Lorrimer, for a display of Roses; Mr. Percy Sudden, Wimbome, for Roses.

NORFOLK AND NORWICH HORTICULTURAL SOCIETY'S SUMMER SHOW.

This was held at Norwich on June 25 and 26. Owing to the sudden death a few weeks ago of the hon. secretary, Mr. C. E. Pilling, the duties were kindly undertaken by Mr. J. E. T. Pollard, a former hon. secretary. There was a numerical falling off in the entries, though the standard of exhibits was well maintained; in fact, in Roses and fruit it was ahead of what we have seen at the Norwich Show for several years past. Though styled a Rose show, the exhibits are of general character. The premier prizes for the open Rose classes were all secured by Messrs. J. Burrell and Co., Cambridge. The show had evidently suited them at the critical moment, for their blooms had just that freshness and perfection of shape so much desired by exhibitors. Their varieties were right up to date as well. Messrs. F. Cant and Co. ran them second in every case. In the amateurs' section the executors of the late R. Steward, Saxlingham, beat all comers, even the Rev. J. A. L. Fellowes, a well-known local grower, going down second to them. In the classes generally, one could but notice the tendency toward the yellow-tinted Hybrid Teas. This fact was specially noticeable in the small classes. Rambler and garden Roses do not seem to display their charms and beauties when bunched up in stands, and as a consequence are generally passed by when the ordinary visitor goes his rounds.

Sweet Peas are now a recognised feature at any summer show, and a fine display was made at Norwich. In the competitive section Mr. E. Wilby, gardener to F. A. Bainbridge, Esq., Hethersett, won premier position and holds a ten-guinea challenge cup presented by Messrs. Daniels Brothers, Limited, Norwich.

There was an exceptionally good show of herbaceous flowers. For forty-eight bunches, distinct, Mr. W. Chettleburgh, gardener to Colonel Ross, Worstead, was

a well-deserved first. His collection was very comprehensive, and the bunches bold, yet not heavy. Mr. W. Hilson, gardener to Sir Frederic Adair, Flixton Hall, was first for thirty-six bunches, the colouring of many of his subjects being most vivid. A dozen bunches of choice varieties were staged by Mr. Frank Neave, Lingwood, with which he secured first place in that class.

Carnations for competition came strongly from that veteran exhibitor Mr. W. Allan, Ginton Hall Gardens, easily securing his premier position.

Exotic and greenhouse flowers were best by far from Mr. Hilson (Sir E. Adair's gardener). There were many smaller classes for cut flowers in addition to those referred to.

Fruit was a prominent feature, and more especially does this remark apply to the classes for Strawberries. Mr. W. Hilson was first for a collection of fruit. His Grapes had a delightful finish. Mr. W. P. Wright, gardener to W. J. Birkbeck, Esq., Stratton, had a wonderful dish of Leader Strawberries, easily first in their class. Mr. F. J. Enderby, gardener to J. H. Gurney, Esq., Keswick Hall, had as good a collection of four varieties as one could wish to see. This exhibitor was also first for a scarlet-fleshed Melon with a new seedling of his own raising. There were also classes for Peaches, Nectarines, Cherries and Raspberries, and in each class good examples were staged.

In the vegetable section Mr. W. Chettleburgh, gardener to Colonel Ross, scored quite a phenomenal success, winning first for a collection and the same position in seven other classes with a strong competition. The Cauliflowers from Mr. Enderby and from Mr. W. Marjoram, gardener to W. T. F. Jarrold, Esq., Thorpe, were in each case fine examples of good culture.

The trade growers made a display unequalled in the annals of a Norwich summer show. Messrs. Daniels Brothers, Limited, Town Close Nurseries, Norwich, had an assorted group of plants and cut flowers from their own nursery. These were very nicely arranged and educational from a gardening standpoint, and reflected credit upon the firm for their high culture.

Messrs. A. J. and C. Allen, Norwich, exhibited Roses of all types and in all ways—pot plants, groups of cut flowers and individually. Needless to say, they comprised the latest and best.

Hobbies, Limited, Berham, had a stand devoted entirely to Roses. The feature of it was the display of their own novelties Pink Pearl, Effective and Lemon Queen. There were others as well in profusion.

Mr. H. Morse, Westfield Nurseries, Eaton, and Mr. E. Morse, Eaton Dell, Norwich, both made interesting exhibits of Roses, embodying only the very newest and choice sorts.

Mr. Robert Holmes, Tuckwood Farm, Norwich, had Sweet Peas in profusion. Many of these, we noted, were under numbers, and for one, the colour of which we should say was orange red, he received a first-class certificate. The visitor was able, too, to see splendid examples of Edith Taylor, Lilian, Queen Mary and other of his novelties.

Mr. W. J. Unwin, Histon, made a display of Sweet Peas that opened one's eyes in wonder. Boldness of flower, length of stem and every other desire of the exhibitor were as they should be. We need not name any. His own leading sorts were well to the fore, as well as the best of those of other raisers.

Messrs. G. Stark and Son, Ryburgh, also had a display of Sweet Peas, and mention of two must be made, viz., Maggie Stark and Deccator. These are worth a place in every collection.

Mr. G. W. Miller, Wisbech, had Orchids in pots and a miscellaneous group of herbaceous flowers.

Messrs. Young and Co., Cheltenham, displayed such an array of Carnations as one rarely sees at a provincial show, the quality and colours being superb.

RICHMOND FLOWER SHOW.

Roses were the leading feature at Richmond on the occasion of the annual flower show, held on June 25 in the spacious Old Deer Park.

Keen interest was displayed in the large class for forty-eight Roses, distinct, three blooms of each. Messrs. R. Harkness and Co. were first with a grand collection, of good quality throughout. Messrs. B. R. Cant and Sons and Messrs. D. Prior and Son were second and third respectively.

Messrs. W. and J. Brown were first for twelve Teas of one variety with that lovely Rose Mme. Jules Gravereaux. Messrs. Burch and Messrs. Prior both following with the same variety. The blooms of the first-prize stand were, however, somewhat over-dressed.

Messrs. W. and J. Brown, Peterborough, were first for twenty-four Roses, distinct, three blooms of each. The best blooms were Mme. M. Souper, J. B. Clark and Caroline Testout. This proved a well-contested class, the second and third prizes going to Messrs. G. and W. H. Burch, Peterborough, and Messrs. R. Harkness and Co., Hitchin.

For twelve blooms of one variety, Messrs. G. and W. H. Burch led the van with a grand box of Lyon Rose, followed by Messrs. R. Harkness and Co. with Mrs. John Luing, and Messrs. D. Prior and Son with Bessie Brown.

The Rev. L. E. Chalmers Hunt, Letchworth, was first for twenty-four Roses, distinct (amateurs only). His blooms of J. B. Clark, Avoca and Mildred Grant were perfect. The Rev. J. H. Pemberton, Ilavinger-atte-Bower, was placed second with a heavier set of blooms of almost, if not quite, equal quality.

Messrs. G. Jackson and Son, Woking, also had a fine group of Roses, in which Mme. Ravary, Dean Hole and Le Progrès were shown in great form.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Alteration of Date of London Daffodil Show.
We are officially informed that the Royal Horticultural Society's 1914 Daffodil Show will be held on Wednesday and Thursday, April 15 and 16, and not on April 21 and 22 as previously officially notified.

Border Pink Nellie.—A good companion to Pink Mrs. Sinkins will be found in the variety Nellie, the deep fringe of the petals being white and in some flowers slightly suffused with violet, the central portion being distinctly blotched with a rich purple or purple-maroon colour. The habit of the plant is dwarf and compact. It is very free-flowering and delightfully fragrant.

Propagating Campanulas.—The present is a good time to propagate by cuttings most of the alpine Campanulas. Some of them bloom so profusely that there is a difficulty in getting cuttings from them. When selecting cuttings, preference should be given to those exposed to full light. Use pots of sandy soil and place in a close, shaded frame till rooted. The following are all desirable varieties: *Carpatica* Little Gem, *c. Riverslea muralis*, *turbinata*, with its varieties *Isabel*, *grandiflora* and *alba*; and *pusilla* and its varieties *pallida* and *Miss Willmott*.

The Lyon Rose.—Is this beautiful though indescribable Rose improving with age? We are tempted to ask this question after seeing the many glorious examples of it last week at the great London show, and also in many gardens that we have visited. The flowers seem to be of a richer coppery shrimp pink colour than ever, while in form they also appear to have gained some points. If only it would hold up its head better in the garden and give us flowers as good as it has done this year, this Rose would claim a first place in our estimation as a garden variety.

Pruning Climbing Roses.—A few of the earliest flowering varieties are over, and those that are not likely to produce a second crop of bloom, such as *Tea Rambler*, *Polyantha simplex* and *Carmine Pillar*, may have the old flowering wood cut out, thus giving the young growth every chance of developing properly. This early pruning may not commend itself to those who like to see their arches and pillars well clothed all the summer, but the results obtained from such treatment are good enough to warrant it being done, and it is really astonishing how quickly the young growths develop.

Campanula pusilla Miss Willmott.—Possibly no individual plant attracted more attention at the recent Holland House Show than this charming Bellflower. In colour the flowers are of a beautiful silvery blue, and are borne in wild profusion. So popular has this *Campanula* become that no rock garden can be considered complete without it. A specialist in alpinism was recently heard to

remark that this distinct variety is the most saleable of all alpinism, and yet it has never been granted even an award of merit by the Royal Horticultural Society.

A Useful Hardy Flower for Cutting.—In the modern craze for novelties the merits of many of our older garden flowers are in danger of being overlooked. This was brought vividly to mind a few days ago when we saw some old Cornish pitchers faintly filled with the *Goat's Rue*, *Galega officinalis*. Few hardy flowers could, with so little trouble, be induced to give such a charming effect, the clusters of sky blue, Pea-shaped flowers, with the dainty green pinnate foliage, lending themselves well to artistic arrangement. This plant is very easy to grow, and will give armfuls of beautiful flowers and foliage for a slight outlay of trouble.

A Beautiful Evening Primrose.—Among herbaceous plants which are flowering at the present time, few are more attractive than the charming little Evening Primrose known as *Eurotia frutescens* Youngii. It makes an erect and neat plant from 2½ feet to 3 feet high, the columnar stems being for some weeks well furnished with brilliant golden yellow blossoms. The buds are enclosed in a sheath of orange scarlet hue, and this, combined with the bright yellow of the fully-opened flowers, adds to the charm of the plant. Unlike the common Evening Primrose, *Eurotia biennis*, the flowers of *Youngii* remain open all day. It is a perennial plant, and one worthy of inclusion in any garden.

Mendel's Law and Variation in Plant-Life.—Dr. H. F. Osborn, writing in the current issue of the *Orchid Review*, says: "The brilliant progress in heredity of the last nine years, beginning in 1903 with the rediscovery of Mendel's law, should not blind us to the four broad inductions from paleontology, that transformation is a matter of thousands or hundreds of thousands of years, that to the living observer all living things may be delusively stationary, that invisible tides of genetic change may be setting in one direction or another observable only over very long periods of time, that discontinuous mutations or saltations may be mere ripples on the surface of these tides."

The Great Rose Show.—The immense strides that have been made in the evolution of the Rose were well demonstrated at the great London show held under the auspices of the National Rose Society on Friday of last week. Perhaps it is in what are termed garden Roses that the greatest advance has been made, and it speaks volumes for the acumen of the Council in providing special classes for these a few years ago. The most charming features of this record show were these decorative Roses in baskets and in vases, though to the exhibitor the large single blooms in vases naturally appealed most strongly. A report of the show, together with a description of the new Roses that gained awards, will be found on another page.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

An Interesting Old Rose.—I am sending the enclosed Rose to ask if you can tell me its name. It is from a very old tree, and in general growth and appearance resembles the common Maiden's Blush, but when fully open the flowers are pure white. It is locally called the Ointment Rose, as its petals are used for that purpose by country housewives in this neighbourhood. It is scarcely ever attacked by any insect or blight, and is never either pruned or manured. It flowers profusely every summer (wet or fine), and appears to me to be vastly superior to the majority of modern rambling Roses.—ANNE AMATEUR, *Lindfield, Sussex*. [The Rose is one of the varieties of *Rosa alba* named *Blanche Belgique*. It is a very good old variety, but not much grown now.—ED.]

Rosa sinica Anemone.—The short note on page 340 of last week's issue by no means over-praises this beautiful but rather tender Rose. It is one of the earliest to open and thoroughly distinct in colour. I would like to call attention to the newer hybrid of this, named *Mrs. A. Kingsmill*. Unlike the type, this is a dwarf grower, has the additional merit of being perpetual blooming, and is particularly good during late autumn. Curiously enough, it also differs by having the lovely shadings of the type reversed, these being on the upper instead of the under surface of the petals. The raisers, Messrs. George Paul and Son, note that the exhausted flowers of this variety should be promptly removed as an aid to its better growth.—A. P.

Silver-Leaf Disease in Apple Trees.—Your correspondent Mr. E. Molyneux on page 322, issue June 28, gives readers some information about the silver-leaf disease of fruit trees which is startling. Both Plums, Peaches and Nectarines have been from time to time affected by this disease, but I have never heard of Apple trees suffering from it. If, however, Mr. Molyneux's remedy proves quite successful, he will have rendered a good service to fruit-growers. In my own case I have had Peaches and Nectarines affected and all remedies applied failed, the trees being finally uprooted, as fresh branches were diseased every year. The trees were grown on an old nursery site, and I was told that silver-leaf was more prevalent when the trees were grown in such soil than when grown in newly-broken ground. I have never seen the whole of a tree diseased in one season, only odd branches, the others being quite sound and healthy.—B.

The Japanese Iris.—May I enter a protest against the note on "The Japanese Iris" on page 347 of last week's issue? *Iris laevigata* is

a totally distinct species from *I. Kampteri*, from which all the so-called Japanese hybrids have arisen. Both species grow, apparently in proximity, in the Amur district of Manchuria, but they are easily differentiated by the fact that the leaves of *I. Kampteri* have a distinct midrib, while those of *I. laevigata* are smooth. The capsules and seeds are also very different. *I. laevigata* is still a very rare plant, although a quasi-albino form of it has long been known under the name of *I. albo-purpurea*. The typical plant has an unbranched stem and a head of three or four flowers, which open in succession. The colour is an intense blue-purple, and in its best forms this Iris is, to my mind, the best of all blue-flowered Irises. I have this year had a

ROSE QUEEN MARY, AWARDED A GOLD MEDAL AT THE NATIONAL ROSE SOCIETY'S EXHIBITION. SHOWN BY MESSRS. ALEX. DICKSON AND SONS, LIMITED. (See page 17.)

number of seedling plants in flower, which showed very little variation except in the exact shade of blue. Colour alone cannot, of course, be relied upon as a specific character; but, so far as I have been able to discover, wild *I. Kampteri* is always of a red-purple colour.—W. R. DYKIS.

Worms in Lawns.—With further reference to the subject of worms in lawns, I should like to give you a few particulars of my experience as an ordinary amateur in this direction. I generally happened to have lived in districts where the soil is heavy, and I have come to the conclusion that it is a great mistake to destroy the worms and also to roll a lawn frequently, as excessive water does

not drain away quickly enough and, consequently the lawn remains very soft, more especially if it should happen to be a slightly sunk one. I have experienced very little trouble with the casts since I have used sand (obtained from the road), which I sprinkle over the lawn very thinly at intervals from autumn to spring, according to the wetness of the weather. This prevents the casts sticking and they are more easily distributed, and even if they are trodden on, the grass easily pushes up again, as the sand prevents caking. I have discarded the use of all artificials, as I find I get better results in the long run by using a mixture of fine loam, rotted manure and leaf-soil spread over very thinly in the autumn and again in early spring. It is astonishing how quickly these dressings are absorbed when the worms are allowed free play, and when the lawn is quite clear I dust it over with slaked lime, in which I am, from experience, a strong believer, particularly in soils of this nature, although I am told it encourages Clover. However, I am not troubled with this, possibly on account of the dressings of sand. I have also found that the grass keeps in better condition during a period of drought under this treatment.—H. B. WHISTLER.

The Parrot's Bill in Scotland.

Cianthus puniceus, the Parrot's Bill, is one of the shrubs which are but seldom found in the open in Scotland, but that it can be grown successfully in specially favoured gardens is evident by the good plant which is on one of the terrace walls of Culzean Castle, Ayrshire, the seat of the Marquis of Ailsa. Here it stands the winter well and flowers on a southern aspect. It covers a considerable space, and is highly decorative with its pretty foliage and its racemes of brilliant scarlet flowers. At Culzean it does not appear to call for any protection, but the position is a very sheltered one and its proximity to the sea tempers the winters greatly.—S. ARNOT.

A Fine Magnolia.—Till within

a recent period the only hardy Magnolia of an evergreen character in our gardens was *Magnolia grandiflora*, from the Southern United States of North America. A second evergreen species has, however, now come prominently forward in *Magnolia Delavayi*, which

was given a first-class certificate at the Holland House Show on July 1. Although so many of the Magnolias now in our gardens are of Asiatic origin, they were all deciduous until the advent of *M. Delavayi*. This species was named in compliment to Père Delavay, who first discovered it in Central China. It was afterwards found by Dr. Henry and Mr. E. H. Wilson, the last named of whom introduced it to cultivation in Messrs. Veitch's nursery at Coombe Wood. It forms a bold-growing specimen, clothed with large, leathery leaves, supported by rather long stalks. These leaves are deep green above and whitish beneath. The flowers are large, egg-shaped and creamy white. H. P.

Scentless Musk.—In reference to your note on this subject in THE GARDEN for June 21, I beg to say that it was noticed here several years ago that the common Musk (*Mimulus moschatus*) was devoid of scent. Since that fact was noticed I fear the old-time favourite has been looked upon as a negligible quantity here, a few odd clumps being allowed to grow at their own sweet will. On reading your note on the subject, however, three of us tried the powers of our olfactory nerve on the plants, but all to no purpose. I have just read the interesting and suggestive letter over the signature "Victoria Slade" in June 28 issue, and shall hope to see other testimonies on the subject.—CHARLES COMFORT, *Broomfield, Middlelothian*

Richardia Mrs. Roosevelt.—This *Richardia*, which formed the subject of a coloured plate in THE GARDEN for June 21, can at the present day hardly be regarded in the light of a novelty, although it is in every way a thoroughly good garden plant. Undoubtedly it would be more popular than it is were the spathes of a clear, decided yellow colour. It was shown by the late Mr. Amos Perry of Enfield (whose recent death we all deplore) at the Holland House Show of 1906, when an award of merit was bestowed upon it by the floral committee of the Royal Horticultural Society. At that time it was said to be the result of a cross between *Richardia hastata* and *R. albomaculata*. This is probably correct, though the hybrid form is more vigorous than either of its parents.—H. P.

Where to Grow *Arenaria balearica*.—Some may be misled by the remark on page 314, issue June 21, that this prettiest of very dwarf rock plants is best grown on northern exposures. It grows here like a weed on the face of brick walls facing due south, and on a newly-made rockery it is already taking possession of whinstone and sandstone alike. To show how climate affects this plant, I may add that though it comes up on south-aspected walls in a manner that proves it thoroughly enjoys these places, I do not recollect an instance of its establishing, or even trying to establish, itself in a shaded position or on a northern aspect. It may not be known that it forms an admirable carpeting plant for bulbs in vases, and I constantly make use of it for that purpose when Hyacinths and Tulips are transferred to these in spring. It is an exceedingly happy-go-lucky plant, and never resents removal, while the tiniest piece, like some of the wee *Sedums*, takes hold and establishes colonies in most unexpected positions.—R. P. BROTHERSTON, *Prestonkirk, N.B.*

FORTHCOMING EVENTS.

July 14.—United Horticultural Benefit and Provident Society Meeting.

July 15.—Royal Horticultural Society's Exhibition. National Rose Society's Show at Gloucester. Southampton Carnation and Summer Show.

July 16.—Flower Shows at Caterham, Uxbridge, Bishop's Waltham, Reigate, and Perry Barr, Birmingham. Nottinghamshire Horticultural and Botanical Show (two days).

July 17.—National Sweet Pea Society's Show at Vincent Square. Dunfermline Rose Show (two days). Dulwich Flower Show.

July 18.—National Carnation and Picotee Show at Vincent Square. North Lonsdale Rose Show. Birmingham Floral Fête (two days).

July 19.—Blackburn Flower Show.

THE ROSE GARDEN.

THE SUMMER PRUNING OF ROSES.

BY the end of July almost the whole of our ramblers and climbers from the Polyantha, Avrshire, Boursault and hybrid wichuraiana sections will have finished flowering; and as the majority of these only bloom once, and then produce their best display from the ripened wood of the previous season, more particularly upon those long maiden shoots so characteristic of this class of Rose, some little attention is necessary towards securing a quantity of such wood in the best possible condition; and it is by a judicious use of the pruning-knife after their flowering is over that this desire can be best obtained. Cut away as much of the older wood as possible, encouraging long growths from as near the base of the plants as you can. Do not fear to thoroughly thin out the centres of bushes and weeping standards, and be firm in the removal of any growths with the slightest tendency to deterioration. This last is of more importance than many apparently imagine, as it has undoubtedly a tendency to develop that peculiar canker and constriction of bark so often found upon many of our strongest growers. A less quantity of young wood, and that properly developed, will always prove more serviceable than a mass of inferior growth, and perhaps never more so than when cultivating this class of Rose.

Some little discretion should be exercised when dealing with our climbers and ramblers that afford later blooms or a short run of a few occasional flowers after their first glut. I would leave some of the best laterals upon these and prune them away during the general pruning of next spring; otherwise one sacrifices a number of useful flowers from varieties of the William Allen Richardson, Rêve d'Or, Climbing Perle des Jardins, L'Idéal and Mme. Pierre Cochet class. There are also a few of the hybrid wichuraianas that provide quite a useful lot of autumn flowers upon the best of their late summer laterals. *Alberic Barbier*, *Alice Garnier*, *Elsie* and the newer variety *Sylvia* are examples, while the beautiful small single white wichuraiana alba, the type or species from which this section of ramblers originated, may be left entirely free of the knife, merely thinning out the spray growths that have flowered when doing the usual spring trimming, as almost all of such laterals will continue to carry trusses of flowers and highly-coloured berries until long after the frosts have stopped the majority of Rose blooms.

Some of our vigorous Hybrid Perpetuals, too, may feel the knife to advantage after their chief flowering is over. I am alluding to such as *Mme. Gabriel Luizet* and *Margaret Dickson*, which seldom bear more than one good crop during the summer, and this upon the best-matured rods of the previous year. A. P.

STANDARD ROSES AND INSECT PESTS.

[In Reply to a Correspondent.]

We think there is a great deal in the observation you make regarding the comparative immunity of blight upon standard Roses as compared with bushes, and it would be interesting to hear the experience of other readers on the subject. One reason for this immunity is that the elevation from the ground-line prevents the insects hibernating in

the soil to a great extent, and another that birds during their nesting season can more readily clear the trees. If one could ascertain the number of aphides a single pair of sparrows will devour in a day, we should not be so ready to condemn this little despised bird. Our correspondent asks for the names of Roses that make good standards. We cannot publish a long list, but name the following as being specially suitable for this form of growth: *Caroline Testout*, *Fran Karl Druschki*, *Gustav Grunerwald*, *Hugh Dickson*, *J. B. Clark*, *Joseph Hill*, *Killarney*, *Lady Ashtown*, *Lyon Rose*, *La Tosca*, *Mme. Leon Pain*, *White Manan Cochet*, *Edward Mawley*, *James Coey*, *Countess of Shottesbury*, *Souvenir de Gustave Prat*, *Sunburst*, *Mrs. Herbert Stevens*, *British Queen*, *Grüss an Teplitz*, *Lady Roberts*, *Mme. Antoine Mar*, *Mme. Abel Chatonay*, *Mme. Jean Dupuy*, *Mme. Ravary*, *Prince de Bulgarie*, *William Allen Richardson*, *Abster Stella Gray*, *Sarah Bernhardt*, *General Macarthur*, *Gloire de Dijon*, *Gustave Regis*, *Mrs. George Shawyer*, *La France*, *La France de 'So. Laurent Carle*, *Mme. Hoste*, *Mme. Isaac Perere*, *Mme. Melane Soupert*, *Mme. Wagram*, *Margaret Dickson*, *Mrs. John Laing*, *Mrs. Stewart Clark*, *Paula Peace*, *Prince C de Rohan*, *Richmond*, *Souvenir de S. A. Prince*, *Ulrich Brunner*, *Viscountess Edkestone*, *Mrs. A. Mint*, *Mrs. H. Brocklebank*, *Château de Clos Vougeot*, *Arthur R. Goodwin*, *Juliet*, *Betty*, *Countess of Derby*, *Florence H. Veitch*, *George Dickson*, *Lady Pirrie*, *Lady Greenall*, *Melody*, *Lieutenant Chauré*, *Marquise de Ganay*, *Mme. Segond Weber*, *Countess of Hchester*, *Pharisäer*, *Walter Speed*, *Harry Kirk* and *Molly Sharman Crawford*.

IN THE HERB GARDEN.

COMPARED with people who grow Roses or Orchids or rock plants or Carnations, how few there are who pay any attention to herbs! Yet no plants are more interesting and nothing can be more delightful than a garden of herbs when properly designed and taken care of. Unless a fairly favourable spot is given up to them, the full pleasure of such a garden cannot be tasted. Wherever circumstances make it possible, some enclosure separated by hedge or bank or fence from the garden proper should be set apart. In it will be found a sense of rest and healing elsewhere unknown besides a sweetness that is strangely refreshing. Unlike the garden flowers, herbs are what Sir Francis Bacon calls "fast of their smells." If you want to savour them, you must ask for them. Just a touch suffices or the merest brushing of the hem of one's garment as one passes—then the Thymes, the Mints and all the other herbs will show what they are made of.

My own herb garden, though I would not be vain about it and I confess that it is much too small to please me, is a source of interest not only to myself, but to all kinds of people. And why? Because it appeals to so many different sorts of tastes and fancies.

First, the cooks. I put them first because in a herb garden it is well to be practical. Why do cooks like it? That is soon told. Because they find in it so much that improves their soups and salads. In the spring and early summer when the herbs are fresh they are at their very best, and it is such a pity that present-day cooks are accustomed to find little else in the kitchen garden

besides Parsley, Mint and Sage. All gardens have these, we must suppose; but why stop there? Why not grow Sweet Marjoram, Curled Chervil, Tarragon, Savory, and both the common and the Lemon Thymes? All these have pleasant and useful flavours. Winter Savory is a perennial, and the young spring shoots are beautifully tender. Later on in the season, however, Summer Savory (an annual) is better, as it is less woody. Marjoram for its sweetness and the Savories for their warm spicy taste are very popular in the kitchen. For different reasons so are Chervil and Lemon Thyme. Tarragon and Basil are more for occasional than for everyday use.

Church people — indeed, all Bible-lovers — seem never tired of seeing such herbs as Myrrh and Hyssop, known so well to them by name. Myrrhis odorata, also called Sweet Cicely, has umbels of charming white flowers, which bloom profusely in the month of May. Hyssop (blue-flowered, a bushy, handsome plant) is still used in the Roman form of consecration. Coriander seeds, perfectly round, with a hot, sweet taste, were compared in appearance to the manna rained down from Heaven to feed the Israelites. They are now used to flavour curries and in making sugar plums.

Antiquarians and people who delight in legendary lore cannot be got out of the herb garden once they are in it! What with old associations and magic, there is no end to their stories. St. John's Wort is one of the amazing plants. If you pull a sprig of it on Midsummer (St. John's) Eve, a fairy horse will spring up from the ground and fly round the world with you before you know where you are. Vervain, which grew at the foot of the Cross, was never gathered by the faithful without a certain prayer being breathed over it. The plant was full of virtue.

Doctors, of course, are interested in seeing the herbs alive and growing, which, as a rule, they only think of when they write prescriptions — Peppermint, for instance, and Dill for fractious babies; Wormwood for bitters; Mallow, Mullein and Elecampane for coughs, Marigold for sprains; Valerian for nerves; and Chamomile as a stomachic.

"A trifle of the herb called dandelion," it may be remembered, gave a smartness to Betsy Prig's famous salad. This herb is still in the British Pharmacopœia.

The day for home-made scents is over, so there is no demand now for Lavender, Rosemary, Bee Balm, Bergamot, or Sweet Woodruff to brew "sweete waters." Most of us like to have these in our flower gardens, all the same, to enjoy their fragrance, but it is to the herb garden they properly belong.

Much more might be said about the pleasantness and usefulness of the herb garden, but this is enough at one time.

FRANCES A. BARDSWELL.

THE FLOWER GARDEN.

THE BLUE-FLOWERED POPPY.

(MECONOPSIS WALLICHII.)

THIS is undoubtedly one of the finest of the Poppyworts in cultivation. It is an extremely handsome herbaceous biennial, and is remarkable as being one of the few, if not the only, truly blue-flowered Poppy in cultivation at the present time. It attains a height of from 4 feet to 7 feet, and forms a perfect pyramid. It is exceedingly beautiful

THE BLUE-FLOWERED POPPY, MECONOPSIS WALLICHII, A BEAUTIFUL PLANT FOR A SHADY CORNER.

when in full flower. The blossoms are about three inches in diameter, broadly saucer-shaped, pendent and of a lovely shade of blue. The blooms always commence to open first at the summit of the stem, then gradually from day to day expand until the lowest and last bud is reached.

Although, as a rule, not more than about twenty flowers are fully open at one time, there is something particularly attractive about *M. wallichii* in full bloom that fascinates plant-lovers. Its curious, deeply-cut leaves, the conspicuous, long, red, bristle-like hairs and the general habit all tend to mark it out among its fellows for special attention. It was first discovered in Sikkim by Sir J. D.

Hooker, and seeds forwarded to Kew bloomed there in the summer of 1852. It forms a rosette of large leaves from 1 foot to 18 inches in length, deeply cut and very brittle, and is a plant that requires a specially-prepared site to grow well. In a peat bed, under the shade of a large Bamboo, as near an imitation of its natural habitat is obtained as is possible in this country. It requires shade, and seems to do best where it can have no chance of seeing the sun at all.

It is unfortunate that, after all its beauty and interest, the plant should die entirely away when the flowering is over, and seed should therefore be sown every year. To obtain the fullest develop-

ment in these plants, seeds should be sown early in the year, say in February or March, the latter date being quite early enough where warmth can be had for the seed-pan. An important point is that of growing on the seedlings briskly from the first, as a check at any of the early stages prior to planting out is calculated to do serious mischief. From the seed-pan the young plants should be potted into equal parts of loam and sandy peat in pots 4 inches across, transferring them to their permanent positions as soon as the roots reach the side of the pot. To delay planting out is to court failure, as the pyramid of blossom in the year ensuing will be in proportion to the development of the plant in the first year. A dozen to twenty plants should be placed in an irregular group at about eighteen inches apart. These, when in full flower, will provide a glorious sight. There is a good deal of difference in the colour of the flowers, and a good strain should be selected. The varieties fusco-purpurea and purpurea are not so desirable as the type, as the blossoms are dull in colour.

WYNDHAM FITZHERBERT.

SEASONABLE NOTES ON CARNATIONS.

Propagation. — There are no plants easier to increase than these, and the result can be achieved by cuttings, seeds, or layers. Of the three the last named is by far the most generally satisfactory, because with reasonable care failure is an impossibility and one knows that the variety will be perpetuated. The same desirable result is, of course, secured when cuttings are rooted; but, unless a man is exceptionally fortunate or skilful, it is certain that the proportion of losses will be considerable. The raising of seedlings is full of interest, and should be done in all gardens each season, since plants of remarkable vigour and floriferousness are thus procured, and now and again one of superb quality is found that is in all respects worthy of perpetuation by layering. The disadvantage of seedlings is that one never knows what one will get, and amateurs, as a rule, do not care to live in such a world of uncertainty. Seeds can be sown out of doors now on a border of light

soil, and the resultant plants will, with proper care, bloom next year.

Layering.—However, the subject of the moment is how best to proceed in layering. Fortunately, the details are simple, and well within the reach of every amateur in the country. The first step is to erect a mound of soil round the plant to be increased. The compost should comprise leaf-soil or refuse manure and sand in addition to the ordinary soil of the garden, and it ought to be built up to such a height that the fixing of the layers will be facilitated. The next point with which to deal is that of suitable shoots. This presents no difficulties, since any growth that shows neither signs of disease nor flower answers admirably. From the lower portion a few leaves must be stripped, and the essential cut should be made with a very sharp knife. Lift the growth carefully, insert the knife underneath, and draw it upwards and outwards through at least one joint—usually a length of 1 inch will suffice. This done, the cut should be so pegged down to the mound prepared that the tongue is kept wide open. To ensure this, many people insert a small stone; but this is not really necessary, as the soil will answer the same purpose if the work is done correctly. The one thing further that is needed to encourage rooting is pleasant and equable moistness, and in normal seasons this is easily secured by the judicious application of water. To attach the layers to the mound, pegs of any convenient kind can be utilised. Those of Bracken Fern are excellent, if procurable, and specially-made pins are purchasable from seed merchants and nurserymen at reasonable prices. It may be well to caution the tyro against making the cut so low down on the shoot as to reach the woody portion, as this usually ends in failure.

Tying and Staking.—With the plants practically at their best, it is of the utmost importance that no detail that will go to the full reward of past labours shall be overlooked. If the flower-stems are allowed to be about in all directions, the blooms will not come to perfection, and those that do develop to a fair state of beauty will not show off their charms. Therefore careful staking and tying are imperative. Avoid the use of heavy sticks and thick strands of tying material, as they are unsightly; but attach each stem in a ligature that will support it adequately without creating the smallest suspicion of stiffness. As with pins for layering, so with supports. Special ones are procurable from the leading dealers, which admirably answer the purpose for which they are intended.

Watering and Hoeing.—The glorious uncertainty of the climate of our beautiful country makes it impossible for one to say whether it will be necessary to water the plants or not; the decision must rest with the cultivator. If the soil is dry, give water to maintain it in a state of moistness; if it is wet, leave the water-pot alone. The value of hoeing is undisputed. Whenever the surface is so dry that the blade of the tool will pass freely through it, use the hoe; or if it

is feared that injury will be done with that tool, open up the top with a small fork or a bluntly-pointed stick. J. H.

SOME GOOD SUMMER FLOWERS.

A CHARMING gathering of flowers lately received from Messrs. Bunyard of the Royal Nurseries, Maidstone, is a pleasant reminder, to one who is now only rarely able to visit nurseries and private gardens, of the advance that is being made in the varieties of some of our best summer flowers. Of these, Irises and Delphiniums, Heucheras, Poppies and Pinks all show variations in some desirable direction. Among those received the following are noteworthy flowers of rare beauty: Iris Mrs. Reuthe is a large and lovely flower of a pale delicate tint, apparently within the pallidas; Delphinium Mrs. Creighton, a very striking bloom, blending blue and rosy purple in a strong metallic sheen; Persimmon, a flower of loveliest pale blue; Queen Wilhelmina, palest blue, flushed with light

No flowers have gained more of late years than the Oriental Poppies. It must have been twelve years ago when I first saw a collection of blooms—I think from Messrs. Godfrey of Exmouth, of orange and pink colourings, some of them already inclining to a salmon tint. More recently we have had the admirable Mrs. Perry, of apricot colouring, followed by the still more beautiful Jeanne Mawson. When one sees a well-bloomed patch of this wonderful flower, one thinks that beautiful development of the Oriental Poppy can go no further. Now Messrs. Bunyard send a charming little flower named Princess Ena, much like a miniature Jeanne Mawson, also a splendid scarlet, Hesperia, and a very dark claret-coloured bloom called Mahoney. For amateurs who have space to spare, nothing is easier or more interesting than the raising of these Poppies from seed. Quite twenty years ago I sowed the seed of a single pod of *Papaver orientale bracteatum*. It was at a time when there was some discussion in the horticultural Press as to

A BEAUTIFUL GROUPING OF IRIS KÄMPFERI MORNING MIST ARRANGED BY MESSRS. R. WALLACE AND CO. AT THE HOLLAND HOUSE SHOW LAST WEEK. (See page 352.)

rosy lilac; Miranda, palest mauve lavender; Cymbeline, brilliant middle blue; Lorenzo, a massive spike of darkest blue. These flowers, all of the solid type, with well-filled spike, bring to mind other good Delphiniums, of which, for ordinary garden use, nothing is more desirable than those so easily grown from seed labelled Belladonna. The resulting plants are not exactly the old and excellent Belladonna, with its wonderfully pure, rather light blue colouring. They have lost the dwarf stature and general air of distinction, but have gained in constitution and are of a habit intermediate between true Belladonna and the taller kinds. They have the Belladonna character of a loose, open spike, and are no doubt near relations of that good old sort—precious plants to have so easily, for I believe the true old kind rarely, if ever, forms seed.

Of the Pyrethrums from Messrs. Bunyard, two, especially, are of great beauty—Queen Mary (flesh pink) and Ivonne Cayeaux (a fine white).

the identity of *bracteatum* with the ordinary *orientale*. I had a large crop of seedlings, many of them producing flowers of great size and beauty. They varied in colour from a very deep scarlet, like that of the usual *bracteatum*, to a bright, light scarlet of the colour of red-lead paint. But among the whole lot there was not a single plant that could be classed as *bracteatum*, with the dark, distinct foliage and stiff, upright flower-stem. It was proof enough that the name *bracteatum* has no botanical value. G. JERVIS.

WATERING SWEET PEAS.

THERE is a great difference of opinion as to the value of watering Sweet Peas during dry weather, but we think all good growers are agreed that a light overhead syringing or hosing with clear water during the evenings of hot days is beneficial to the plants. This not only washes away dust and other injurious accumulations, but puts a decided check to the ravages of insects.

TREES AND SHRUBS.

THE FLOWERING BRAMBLES.

THE genus *Rubus* is very rich in the number of species, but, comparatively speaking, few of them may be described as good garden plants. A list of the best twelve would about exhaust the number of those worthy of general cultivation. These for garden purposes may be readily divided into three groups, e.g. those worth growing for the flowers; a few with ornamental foliage, including two or three evergreens; and several with attractive stems, which are seen at their best in winter when devoid of leaves. The best of the flowering Brambles or Raspberries are three North American species—*Rubus deliciosus* (illustrated), *R. odoratus* and *R. nutkanus*. To these may be added two double forms of our hedgerow Brambles.

***Rubus deliciosus*.**—This is a hardy shrub 4 feet to 6 feet, occasionally more, in height. It is a native of the Rocky Mountains, and was introduced by the late Mr. Anderson Henry of Edinburgh in 1870, though it was known and named from dried specimens fifty years earlier. The leaves and growth of the bushes suggest a Currant bush rather than a Bramble, and it has neither spines nor thorns. The flowering season is May, extending into June. The blooms are white, resembling a single Rose, 2 inches or more in diameter. There are, unfortunately, two forms in commerce, one having much smaller and inferior flowers than the one illustrated. A rich sandy loam suits the plant best, but it will thrive in most good garden soils. Though a perfectly hardy shrub, *R. deliciosus* should be given a warm, sunny spot in the garden to obtain the full beauty of the bushes; in fact, in cold districts it is worth a place on a sunny south wall. The usual method of propagation is by layering, as cuttings do not root readily. During a favourable summer the plants sometimes produce fruits, when seeds are available as a second means of propagation. The name "deliciosus" was given to the plant presumably to describe the flavour of the fruit, but the traveller when he discovered the fruits of *R. deliciosus* must have been very weary and thirsty to describe them as delicious. The fruits of our hedgerow Blackberries are far preferable.

***R. odoratus*.**—This is a very old introduction from North America, and is figured in one of the earlier volumes of the *Botanical Magazine*, t. 323. It is vigorous and free in growth, sending up strong canes annually to a height of 6 feet to 7 feet, like the garden Raspberry. The suckers spread rapidly in the surrounding ground in most soils, soon forming large clumps or groups. The flowering stems should be cut down to the ground in autumn,

leaving only the young, vigorous shoots. The largest of the handsome leaves measure 10 inches to 1 foot across. The rosy purple flowers exceed two inches in diameter, and are borne in succession from early June to September. The Purple-flowering Raspberry, to use the common name, is a valuable plant for shrubbery borders in large and small gardens. The suckers, which, as before mentioned, push up freely, form a ready means of increase, and the plants will thrive in most soils in sun and shade.

***R. nutkanus*.**—This species, from the fact that it was first discovered growing in the Nootka

Bramble is *R. thyrsoides flore pleno*, the nursery name *R. fruticosus flore albo pleno*. The most important recommendation possessed by both these plants is that they do not flower till late summer and autumn, when most of our hardy shrubs are over.

Being of loose, rambling habit, to all intents and purposes like our hedgerow Brambles except when in flower, they should be planted in the pleasure grounds, shrubbery borders and woodland; not in the carefully-trimmed beds of the formal garden and terrace. Here, when the long, arching growths are freely clothed with blossoms, they are most effective. With age it becomes necessary to cut out as many of the old dead growths as possible, or in time the groups look somewhat dishevelled. There are few soils in which these Brambles will not grow. Layering is the usual method of propagation, while cuttings will also root, though the percentage of successes is sometimes not very encouraging.

FLOWERING SPRAYS OF THE THORNLESS BRAMBLE, *RUBUS DELICIOSUS*, AN INTERESTING SHRUB FOR A WARM SITUATION.

Sound district, is sometimes referred to as the Nootka Raspberry, also as the Salmon-berry. In foliage and growth it closely resembles *R. odoratus*, but the flowers are white.

Double-Flowered Brambles.—While all agree in calling them double-flowering Brambles, we possess in gardens a double pink and a double white *Rubus*, to which botanists and nurserymen give several names. In the "Kew Hand List" the pink-flowered form is named *R. ulmifolius flore pleno*. One nursery catalogue gives it as *R. fruticosus roseo pleno*, and a second *R. bellidiflorus*. The Kew name for the double white

Amaryllis will always give the best results when cramped in small pots. At no time need the pots be larger than the 7-inch size, and very fine flowers are grown in 5-inch pots. Instead of repotting, it is therefore best, usually, to merely top-dress with rich soil to which has been added a fair quantity of Thomson's Plant Manure.

By the beginning of June with the early batch, and by the first week in July with the latest plants, growth should be complete. It is then that the most important part of the summer treatment must be given. Some writers advise placing the pots in cold frames, but for various reasons I

GREENHOUSE.

SUMMER TREATMENT OF THE AMARYLLIS.

JUDGING from what one sees in even good gardens, a considerable amount of ignorance prevails in connection with the summer culture of this showy and useful stove bulb. Plenty of growers get along all right with freshly-bought bulbs, but, after flowering them well the first season, have no more success. In too many cases the reason is not at all difficult to discover. As soon as the flowers fade, the pots are placed under the stage, where they either get too much or too little water and no light to speak of. This is entirely wrong, and the finest bulbs in existence would fail to thrive under such conditions.

The proper way to treat the stove *Amaryllis* (*Hippeastrum*) after flowering is to place the pots in a warm house, say, where a fairly steady temperature of about 70° can be maintained. Should any repotting be necessary, attend to this before placing the plants in heat. Personally, I see no necessity for repotting oftener than every three to five years, as the

prefer a sunny greenhouse in which to properly ripen off the bulbs. An open lath stage is the best place for them, and they must receive full sunshine. Water must be given whenever necessary, and twice a week liquid manure, or, better still, Ichthudin Guano in water, must be given until the foliage begins to show signs of turning yellow. When this occurs, drop the feeding, but do not entirely stop watering. Indeed, the soil should at no time be allowed to get dust dry, although very little water will be necessary after the foliage dies down—just enough to keep the roots from dying. This is most important, for, naturally, a bulb which retains fresh, healthy roots has a great advantage over one that has been entirely dried off, when the roots have to start into growth again. As soon as the foliage dies down, the pots may be set under the stage, a moderately warm greenhouse being better than a stove for storing the bulbs during winter. To sum up, the *Amaryllis* should, during summer, be set on a dry, sunny stage, be well attended to with water, and fed frequently with weak liquid stimulants until nearing maturity, when water only should be given, and this latterly in great moderation. C. BLAIR.
Preston Gardens, Louthgow.

LIBONIA FLORIBUNDA.

This lovely warm-house plant is not grown as extensively as it ought to be by amateur cultivators. It is a really beautiful plant for a warm greenhouse, and flowers during the autumn and early winter months when flowers are scarce. Its red and yellow blossoms, gracefully depending from the branches, harmonise agreeably with the prevailing colours and autumn tints. Old plants are often badly infested with red spider, but these minute insects can be kept away if the plants are regularly syringed. There is, however, a better way of growing fine plants, namely, by treating them as annuals from cuttings. The young plants make bushy subjects, and the flowers borne on them are large and highly coloured. During the summer months the young plants may be grown in a cool frame, so that there will be no need to sacrifice space in the greenhouse to them at that period. Take off strong shoots about three inches long, insert them in a mixture of loam, leaf-soil and sand in small pots, and place the latter in a propagating-frame, or in a box covered with glass, placed on the hot-water pipes. When sufficiently rooted, pot the cuttings separately in 3-inch pots, using a similar compost with the addition of a small quantity of old mortar rubbish and well-rotted manure.

Retain the plants for a few weeks in a warm house or pit where a moist atmosphere can be maintained. Repot the plants as they require more rooting space, using the compost in a slightly rougher state, and confine them to a frame from the early part of June to the early part of September; then transfer them to a warm greenhouse. Feed the plants with weak soot-water and liquid manure when they are well rooted. It would be possible to buy a few young plants now to grow on for flowering next autumn and winter. AVON.

ROCK AND WATER GARDEN.

THE ALPINE POPPY.

WERE it not that one knows too well the troubles that await the cultivator of *Papaver alpinum* when grown in the ordinary way, one would wonder at its absence from so many good gardens. It is a lovely little gem—a vastly-reined Iceland Poppy—with foliage of the most delicate character, both in form and colouring, and a picture to look upon, either in or out of flower. A charming plant, with leaves as if carved out of frosted silver or made of silvery lacework, it bears dainty little flowers of varied colours fitted gracefully on stems some six inches high, and gives a succession of blossoms for a long time. They are of many lovely shades,

among the clumps of this moraine, the plants will stand for years, and will give a long period of lovely blooms, seeding themselves in favoured places and forming dainty groups of charming foliage and even more charming flowers. S. ARNOTT.

A CHARMING ASSOCIATION OF ALPINE FLOWERS.

THE accompanying illustration shows two beautiful alpine plants in happy association. The small-flowered plant on the left is *Erinus alpinus*, native of the mountains of Western Europe, but naturalised here and there in Britain. It is cherished in the rock garden by virtue of the fact that it is one of the most useful crevice plants in cultivation. Moreover, it is an admirable wall plant, and may easily be established on a wall by sowing seeds in crevices that have been filled in with stony or

POTENTILLA GRANDIFLORA AND ERINUS ALPINUS FLOWERING SIDE BY SIDE IN THE ROCK GARDEN.

from white through roses to almost scarlets and yellows. A nice variety is given by the *laciniatum* strain, which has daintily-lacinated petals. The barrier to the cultivation of *Papaver alpinum* lies in the fact that it appears to suffer badly from wet in winter, while one would whisper also that the slugs are not innocent of the destruction of many of these exquisite little alpine Poppies. They can be transplanted in showery weather, especially when small; but the best course is to buy a packet of seeds, and either to sow very thinly in sandy soil where they are to bloom, or to sow them as thinly in pots of sandy soil, just covering the seeds and pricking out the seedlings where they are to flower, or into 2½-inch pots, whence they can be planted out with the ball intact. Given a very dry position in extremely light, sandy and gritty soil, they may stand wonderfully well; but there can be no manner of doubt that the moraine is the place *par excellence* for the alpine Poppy. Planted

gritty peat and loam. The flowers, which are profusely borne in clusters almost clinging to the face of rocks, are variable in colour, but are generally lilac or rosy purple, while the variety *alba* is a white counterpart, and flowers with almost, if not quite, equal freedom. The large-flowered subject of the illustration, bearing a strong resemblance to a Buttercup, is *Potentilla grandiflora*. This is a time-honoured favourite of our gardens, having been introduced from Southern Europe as far back as 1640. Its bright golden yellow flowers are abundantly produced above the Strawberry-like foliage. The flowers of both subjects are produced in early summer, but, like many of the pleasing combinations among alpine flowers, the happy effect here produced was the result of accidental planting. It is, however, an effect worth noting, and those who garden for early summer effect should certainly plant these subjects in close proximity to one another.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Adiantum trapeziforme Queen Mary.—A very handsome and erect-growing variety of this well-known species. The fronds were about two feet in length, the pinnæ of unusual size. From Messrs. H. B. May and Sons, Edmonton.

Magnolia Delavayi.—By reason of its vigour as a young plant, this remarkable species presents all the promise of tree-like proportions when fully grown. The flowers are of creamy hue, deepening into pale lemon colour. The handsome leaves are 9 inches or so in length and 4 inches wide, ovate-acuminate in outline, and with slightly undulated margins. From Messrs. Veitch and Sons, Limited, Chelsea.

AWARDS OF MERIT.

Adiantum siebertianum.—A pretty and distinct new species, the fronds having the outline somewhat of *A. assimile*, though stiffer and more erect-growing, and of a crispate character throughout. In youth the fronds assume a pretty red tint that is most pleasing.

Polypodium Mayi cristatum.—This is practically self-descriptive of one of the best types of greenhouse Ferns. *P. Mayi* is a strong-growing form of *P. aureum*, the cristate character noted in the present variety adding beauty to a pleasing form. Both these were shown by Messrs. H. B. May and Sons, Edmonton.

Nepenthes atropurpurea.—The pitchers are of crimson brown hue, the collar beautifully frilled. A very handsome variety of considerable decorative value.

Nepenthes Lewis Bradbury.—In this the pitchers are green and brown, somewhat mottled or freckled. Like the foregoing, it is a handsome kind and of considerable vigour. These were exhibited by Messrs. J. Veitch and Sons, Limited, Chelsea.

Iris Kæmpferi Morning Mist.—The variety is certainly a very beautiful and effective one, the flowers large in size, the white ground covered almost by a shading of blue, which renders it most attractive. A little colony of this variety is illustrated on page 349. From Messrs. R. Wallace and Co., Colchester.

Carnation Virginia.—A good yellow-ground fancy, streaked and flushed cerise.

Carnation The Baron.—Also a yellow-ground fancy, marked with rose. Both are excellent in their way. Exhibited by Mr. J. Douglas, Great Bookham, Surrey.

Erigeron hybrida Pink Pearl.—The colour is pinkish buff, with perhaps a slight shading to deeper pink as the flower ages. The plant is about fifteen inches high, of good habit, and flowers

quite freely. Among the *Erigerons* the colour is quite unique and good. Shown by Mr. Amos Perry Enfield, Middlesex.

Rose Muriel Dickson.—A Hybrid Tea of deep glowing vermilion scarlet colour. The flowers are of good size, conical form and fragrant.

Rose Mrs. Godfrey Brown.—This also is a Hybrid Tea, the flowers being very large and pale flesh pink in colour. Of conical shape, very full and slightly fragrant.

A BEAUTIFUL NEW HYBRID ORCHID, MILTONIA SANDERÆ, SHOWN AT THE HOLLAND HOUSE EXHIBITION LAST WEEK.

Rose Ulster Standard.—A very deep crimson single-flowered variety. Judging by the sprays shown, it has a very vigorous habit, and the flowers are very fragrant. The three foregoing Roses were shown by Mr. Hugh Dickson, Belfast.

Rose Ophelia.—A lovely variety with pink centre and outer petals of paler hue. Shown in quantity by Messrs. W. Paul and Son, Waltham Cross.

NEW ORCHIDS.

FIRST-CLASS CERTIFICATES.

Odontioda Brewii.—A new hybrid, quite distinct from anything yet seen. Parentage: *Odontioda Charlesworthii* × *Odontoglossum harrimanii*. In colour it is crimson maroon, and it is claimed to be the darkest *Odontioda* yet raised. The lip is large with a golden crest. The form of the flower is not good, but by virtue of its remarkable colouring it is likely to be the forerunner of a new type. Shown by Messrs. Charlesworth and Co., Hayward's Heath.

Miltonia Sanderæ.—This remarkable hybrid is illustrated on this page. The flowers are pale in colour, which makes the dark maroon eye all the more conspicuous. It was raised by crossing *M. St. Andre* with *M. vexillaria* G. D. Owen. Shown by Messrs. Sander and Sons, St. Albans.

Miltoniodes Harwoodii Fowler's Variety.—The new-comer is a great improvement, both in colour and form, on this bigeneric hybrid. Shown by J. G. Fowler, Esq., South Woodford.

AWARDS OF MERIT.

Three new *Cattleyas* received awards of merit, viz., *C. Mossie Dreadnought*, a bold flower with large crimson lip with golden base, from Messrs. Sander and Sons; *C. Serenata*, a bright rosy pink of striking colour, from Messrs. Mansell and Hatcher; and *C. Mossie Olympia*, a beautiful variety of perfect form with soft mauve pink flowers, from Messrs. Charlesworth and Co. Messrs. Charlesworth and Co., Hayward's Heath, also gained an award for *Odontioda Wilsonii Le Président*, with peculiarly mottled rose pink flowers of regular outline and borne in graceful inflorescences.

The foregoing plants were shown at the Holland House Show last week when the awards were made.

A GRAND WALL SHRUB.

(*ESCALLONIA LANGLEYENSIS*.)

THOUGH now fairly well distributed, the merits of this hybrid *Escallonia* as a wall shrub are often not recognised to the extent they might be. It was raised in Messrs. Veitch's nursery at Langley, the parents being the red-flowered *Escallonia macrantha* and *E. philippiana*, whose flowers are white. Generally speaking, it is about midway between the two, the leaves being smaller than those of *macrantha*, while it inherits a good deal of the spreading gracefully, arching habit of the other parent. This feature is most pronounced when the principal branches are secured to a wall or other support, and the minor ones allowed to dispose themselves at will, which they will do in a pleasing and informal manner. H. P.

GARDENING FOR BEGINNERS.

HOW TO PROPAGATE ROSES BY SUMMER CUTTINGS.

THE amateur gardener, and particularly the beginner, will find the varying methods of propagating or increasing plants one of the most interesting phases of gardening. At all seasons of the year there is little or much work to do with a view to adding to one's collection or stock of plants. It may be seeds to sow, inserting

and from these nodes, when inserted in the soil, roots may be expected to push out. In taking off the bottom leaf be careful not to injure the bud in the axil, as later on any of such buds which are below the surface will push up and produce those strong basal shoots which rosarians delight to see pushing through the soil. Cuttings $4\frac{1}{2}$ inches to 5 inches long when made ready for insertion, with three or four leaves, are a good average length. Light, sandy soil may be used for filling the cutting-pots, but a larger percentage of rooted cuttings may be looked for if sand alone is used. Insert four or five cuttings in 4-inch pots. The rooted cutting illustrated is inserted in sand, the photograph being taken twenty-five days after it was put in. This is ample evidence of the value of sand as a rooting medium. There is also much less liability of cuttings damping when sand is used; it is clean to handle, and when potting off the rooted cutting the sand falls away readily from the young roots. Should a few of the leaves fall off the cuttings a week or more after insertion, fears of non-success need not be entertained, provided the buds in the axils of the leaves remain plump.

along a lot, and by April, nine months from inserting the cuttings, nice plants should be available to plant out in the borders. These will give a few nice flowers during the summer and a plentiful supply in autumn if mulched, watered and carefully tended.

HOW TO GROW GOOD LATE TURNIPS.

You see, succulent Turnips are always appreciated more than those of a tough, stringy nature. It is a difficult matter to avoid a certain amount of toughness in roots raised during the hot days of summer, however careful one may be as regards cultivation. Where the summer-raised roots must be depended upon for use in the early part of, and through, autumn well into the winter, it is a good plan to lift some of them while still in a tender condition as regards flesh, and bury them in the ordinary soil on the north side of a wall or fence. The tops must be cut off, of course, and the roots buried, without washing, in the pit, being covered by quite six inches of soil. So treated, they will remain sound for many months. Where it is possible to raise young roots, however, these should be preferred. In August and through September the young roots swell rapidly.

The Soil and the Sowing of the Seeds.—Many persons are under the impression that Turnips to bulb well must be grown in hard ground, in soil well firmed by treading. Even in naturally light soils it is not necessary to firm them beyond the ordinary breaking up, drilling and raking afterwards. In heavy loams a thorough breaking up is very desirable, otherwise it is inadvisable to trample on them any more than can be helped. In quite clean ground a pinch of seed may be sown broadcast and raked in; but where small weeds are troublesome, sow the seeds in shallow drills 14 inches apart, and hoe frequently between the rows of young plants. SHAMROCK.

1.—ROSE CUTTINGS IF TAKEN NOW AND PLACED IN A FRAME WILL ROOT IN A FEW WEEKS.

cuttings, or a little budding and grafting. Among a considerable number of plants which are popular with the amateur grower, the Rose undoubtedly holds first place. While most of the Rose bushes we purchase have either been budded or grafted, most sorts, particularly the strong growers, give excellent results when propagated from cuttings. Those popular Hybrid Teas Caroline Testout, Mme. Abel Chatenay, Lady Ashtown and Killarney, the Hybrid Perpetuals Mrs. John Laing, Ulrich Brunner and Fran Karl Druschki, and the Rambler Roses Dorothy Perkins, American Pillar and Mrs. E. W. Flight are just a few of the popular sorts which thrive when propagated from cuttings.

There is no better time than July and August to insert Rose cuttings. The usual practice is to insert cuttings outside during October and November, leaving the young plants in the cutting-beds till the following October. Practically a year, however, may be gained by taking cuttings now and inserting them in pots under glass. The best growths to make the cuttings are the shoots which bear the flowers. These are just in the right condition to insert when the blooms shatter. The shoots may be anything from 5 inches upwards in length. They will be better inserted with just a slight heel of old wood attached at the base, as shown in the illustration. Failing this, cut off the stem just below a leaf; this is termed a node,

when we look for hot, sunny weather, the cutting-frame is preferable, situated on the north side of a wall, hedge, or fence. Here the cuttings will get ample light but very little sunlight to dry up the moisture, which is so necessary to prevent the cuttings from withering. A good soaking of water after inserting the cuttings will probably suffice for two or three days unless the position is a dry one.

In from three to four weeks examine a pot or two of the cuttings, and as soon as the cuttings are nicely rooted similar to the one in the centre of Fig. 2, pot each one off into a small pot, using light, sandy soil. Return the cuttings to a close frame for a few days, and when it is seen they are recovering from the check of removal, air should be admitted and gradually increased as growth proceeds. The next point worthy of note is a move into a larger pot. This time a pot 5 inches wide may be used. Should a little space on a stage in the greenhouse be available for the plants, it will help them

2.—ROSE CUTTINGS A FEW WEEKS AFTER INSERTION. THE CENTRE CUTTING IS ROOTED AND READY FOR POTTING UP.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Rose Garden.

With the first crop of bloom over, many of the Hybrid Teas will be well into growth again; and to encourage this second crop it is well to look after the watering and feeding. Liquid manure may be given *ad lib.*, and, if the plants seem to require it, a dressing of artificial manure may also be given.

Green Fly and Mildew.—At this time, while the plants are fairly devoid of bloom, it is advisable to take a little extra trouble to eradicate green fly, as, after about this date, if the plants are thoroughly cleansed, they seem to keep pretty clean for the rest of the season, and the only pest to combat is mildew. For this there are many preparations on the market which will keep it under, providing the plants are regularly sprayed and the roots kept in good condition as regards moisture.

Budding.—Those who have stocks planted for budding should lose no time in getting the work done. If the weather is unduly dry, a good watering a few days beforehand will ensure the bark running nicely.

The Pleasure Grounds.

Watering Grass.—Where the grass is apt to turn up badly, it is advisable to water pretty frequently. The ordinary sprinkler is a very good friend where there is not much ground to be covered, but where the lawns are extensive it pays to keep a youth at work with the hose. In this way a good deal of ground can be covered, and though the water may not penetrate so deeply, sufficient may be given to keep the grass in the immediate vicinity of the house in a fairly fresh condition.

Plants Under Glass.

Cannas that are throwing up their blooms must be liberally treated, especially when flowering in small pots. Those that are showing colour should be removed from the main batch, as they will not stand the syringe when in bloom, though during the growing season it is very necessary to use it regularly, or spider will quickly make its appearance.

Climbing Roses in Pots.—Where these are again required for flowering under glass next season, they should have very careful attention. After cutting out all the old flowering wood and tying in the growths (say three or four) intended to flower, the pots should be partly plunged in ashes, or in the ground, in such a position where they can be well looked after, both as regards watering and feeding, as the pots, being very full of roots, will be found to dry rather quickly.

Salvia splendens.—These are now growing freely in their flowering pots, and to preserve a bushy habit the shoots should be topped over at every second or third pair of leaves. *Glory of Zurich*, which may be wanted in bloom at the end of August or early September, should not be pinched after the end of this month.

Azalea indica.—These plants, after making their growth indoors, should be removed to the open air, selecting a semi-shady position for them. There is a distinct advantage in watering with rain-water whenever it can be obtained. Lime in the water or in any form is distinctly detrimental to nearly all hard-wooded plants.

The Kitchen Garden.

The hot, dry weather which we associate with July and August often proves a very trying time in the kitchen garden, more particularly on light soils, but much good results from a system of mulching and watering, providing it has not been put off too long. Peas, Beans, Cauliflowers, Lettuces, Celery and Onions—in fact, all the quick-growing subjects—are greatly benefited by a good soaking of water now and again, while a hosing overhead during the very hot weather will do much to preserve a fairly healthy and clean growth. Though I have frequently mentioned the matter of hoeing in this calendar, I cannot too strongly emphasise the good to be derived from it, and when circumstances do not allow of mulching and watering, this is the next best thing.

Eschallots have not done well in this neighbourhood, the growth being poor in most instances. As

soon as the tops have died down, the bulbs should be harvested. Remove them from the soil and lay them out for a day or two before storing them away in the shed. If left in the sun too long after removing from the soil they are apt to shrivel.

Late Peas.—To secure a good crop of late Peas it is necessary to give the plants every attention, and, before staking, they should be carefully thinned, and after carefully hoeing between them, a light mulching of well-rotted manure between the individual plants will do much to keep them healthy.

Fruits Under Glass.

Melons.—For very late crops seed should now be sown, choosing a small, quick-ripening variety. I have tried *Barnet Hill Favourite* this season, and found it one of the best in this respect; it is of excellent flavour. Fruit may be kept some time if removed from the plant before it gets too ripe and placed in a cool, airy fruit-room.

Fruit Trees, either in houses or frames, which are bearing swelling fruits must be kept well supplied with moisture at the roots. In the latter case the fruit trees should be raised up on pots or blocks, so as to keep the fruits dry, and, incidentally, to give them as much light and air as possible. Ventilate freely during bright weather to prevent scorching of the foliage, but shut up the frame early enough in the afternoon, so as to maintain as much heat as possible during the night.

Hardy Fruits.

Gooseberries and Currants that are ripening should be netted to keep off birds, and where it is desired to keep such fruit as long as possible, a piece of tiffany strained above the trees will retard the ripening process and preserve the fruit for a considerable time.

American Blight.—When the Apple trees are affected by this pest, steps should be taken to keep it down, and I have found nothing better than to go over the trees carefully, touching the affected parts with methylated spirit, taking care not to splash the foliage or fruit during the operation. If the trees are gone over two or three times during the next few weeks, it will probably keep them clean for the rest of the season.

THOMAS STEVENSON,

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Adlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Sweet Peas.—Attention must be given to watering if drought sets in, and if the operation is necessary, a good soaking should be given, after which, when the surface has dried somewhat, it should be stirred with the hoe. On light soils especially it will be of great advantage to mulch the crop, and grass mowings or Hop Manure will be found suitable for the purpose. By this means the roots will be kept cool and the moisture conserved.

Auriculas and Polyanthuses.—This is the time to save seed of these popular hardy flowers. The careful cultivator will have marked any specially good variety; but with the strains of seed now supplied by many firms one can hardly go wrong in saving seed for growing in masses. Select dry weather for the work.

Dividing Heucheras.—If these plants are divided just after the flowering period, they will give a fairly good account of themselves next season, whereas, if the operation is delayed until the autumn, little can be expected of them next year. The long, fleshy roots should be shortened with a sharp knife, and they should be planted deeply, so that the foliage only appears above the surface. The Heucheras are very useful for dinner-table and other indoor decorations, the gracillimum section being specially suitable for this purpose.

The Rose Garden.

Pests.—A constant watch must still be kept for the appearance of aphid and mildew, but in dealing with them care must be taken of the blooms. In the event of mildew appearing, a dusting of flowers of sulphur by means of the puff is preferable to spraying.

Spent Blooms should be removed two or three times a week, as if allowed to remain they become very unsightly.

The Rock Garden.

Propagating Aubrietias.—Where an increase of the stock is desired, no time should be lost in setting about the work, as cuttings are difficult to strike after the young growths have ripened. Under favourable conditions, however, Aubrietias root quite readily. The directions given in the calendar during the past few weeks for the propagation of Dianthus and Cheiranthus are quite suitable for Aubrietias. Another method is to work in some sandy loam among the young growths, attending to them with water when necessary, and in due course roots will be emitted. The plants can then be broken up in the autumn.

The Shrubbery.

Lilacs.—See that the decayed flower-trusses are promptly removed, as they are unsightly, and in their attempt to mature seeds the plants are weakened. Suckers should be spudded out.

Layering.—Many of our finer shrubs are best propagated by layering, and this is a good time for attending to this work. There are several methods of layering. One is that of simply sinking the bent-down shoot under the surface of the soil, fixing it in position with a stout peg. A second method is known as twisting, meaning that the branch receives a twist in order to stop the flow of sap and thereby encourage the emission of roots. Splitting is performed by making an incision through the centre of the shoot with a sharp knife, and tonguing is performed in the same way as Carnations are prepared for layering. In each case the branch is sunk below the surface of the soil and pegged down.

Plants Under Glass.

Pelargoniums.—As soon as these have done flowering they should be placed out of doors in a sunny position. All the old flowers should be removed, and if there is any appearance of aphid, the plants should be thoroughly syringed with some insecticide. Gradually diminish the supply of water at the roots.

Late Geraniums.—Plants intended for late autumn flowering should now be in the open, or in frames with the lights tilted high at the back and front. Keep all flower-trusses picked off, and pinch out the points of the shoots to ensure a stubby habit.

Fruits Under Glass.

Melons.—Where these are swelling their fruits, abundance of chilled water must be supplied to the roots, as evaporation is now very rapid. Do not water close up to the stems, or canker may ensue. Where it does appear, rub the affected parts with charcoal dust or powdery lime.

Cucumbers.—Plants which have been bearing for some time should receive the benefit of some fertiliser. Thin out superfluous shoots and pinch the remaining laterals at one leaf beyond the fruit.

The Hardy Fruit Garden.

Strawberry Runners which were layered some weeks ago will now have made good roots, and should be detached from the parent plant by cutting the runner immediately behind the rooted plant. Plants in plantations made in spring should not be allowed to form runners, or they will be weakened.

The Vegetable Garden.

Spring Cabbages.—Seed of these should be sown during the next week. Only quick-heating varieties should be sown. There are a good many of these. We have had a succession of first-rate Cabbages from April to the present time from sowings of *Ellam's Early* and *McEwan's Early Vanack* sown at this date last year.

Spinach.—Sowings made now and onwards for a few weeks will give better results than sowings made a few weeks prior to this date. Spinach never germinates well in rough, lumpy soil. Manure well.

Parsley.—A sowing made now will furnish a winter supply if covered with a frame later on. If the ground is at all dry, water it thoroughly after sowing, as Parsley requires a long period for germination.

The Brassica Family.—Planting of greens, Savoys, Cabbages, Asparagus Kale and Broccoli should now be brought to a close. Water after planting if dry conditions obtain.

CHARLES COMFORT

Broomfield Gardens, Davidson's Mains, Midlothian.

**ANSWERS
TO CORRESPONDENTS.**

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only and addressed to the EDITOR OF THE GARDEN, 20, Pall Mall Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

ARARIS AND AUBRIETIA (X.).—You may take the cuttings of the Arabis at any time. Shoots of 4 inches or 5 inches long, divested of their lower leaves and pricked in sandy soil in a shady place, will root to almost cent. per cent. You can bed out the resulting plants in autumn or spring. Seeds of Aubrietia for providing suitable plants for spring carpet bedding should have been sown not later than March last. Seedlings, however, are not the best for this work, since they vary in height, habit and colour, and in other ways. The only really good way to get effective masses true to colour is by raising a stock from cuttings or division.

CAMPANULA (Mrs T.). From your description the Campanula you are seeking is certainly not *C. muralis*, which is of tufted growth, 6 inches or so high, and in June smothered with its semierect, bell-shaped flowers. *C. garganica* in all its forms is of a carpeting nature, i.e., flat-growing and spreading, the rather small flowers star-shaped and profusely borne from July to September. There are pale blue and white varieties. Another variety with woolly leaves is known as *hirsuta*. The plant would be easily obtained from any good hardy plant nursery. If the Lily bulbs are small as well as weakly rooted, throw them away and start with a fresh stock, planting, if possible, in August. This Lily (*candidum*) begins re-roofing soon after the flower-spikes fade.

ROSE GARDEN.

WARTY GROWTH UPON CRIMSON RAMBLER (Captain A. S. L.).—This growth is caused by the puncture of an insect, and although we do not think there is any fear of infection, we should certainly recommend cutting away all growths affected, as they cannot possibly be of any use.

YELLOW ROSE FOR SOUTH WALL (Mrs. T.).—*Rève d'Or* would be an excellent Rose for your wall. It would be quite hardy enough for a south aspect. The Rose is nicely Tea-scented and blooms perpetually when established. *Bouquet d'Or* would bloom earlier than *Rève d'Or*; that is to say, the plant would bloom the second year after planting. It is also rather more sweetly scented.

ROSE SPORT (J. G.).—Are you quite sure the Rose is a sport? It sometimes happens that a plant has had two kinds of two different kinds budded into the root. If you look carefully and see whether the growth of the sport springs from that of the Rose you name, then, of course, it is all right. You might send us a flower with a piece of growth; then we can see from the wood if it is the same.

THE GREENHOUSE.

INJURY TO CYCLAMEN (Wilton).—The Cyclamen appears to be drying off, and will probably start again into growth. Possibly water has been withheld. The cause of the appearance is some cultural treatment, and not a fungus or insect. The Rose sent is *Alberte Barbary*.

CARNATION SHOOTS FOR INSPECTION (Hales).—Evidently some insect has been puncturing the leaves and sucking out the sap of the Carnation here and there.

Give the plant a watering with a weak solution of sulphate of potash, and if the trouble continues, spray with paraffin emulsion.

MISCELLANEOUS.

LEAF-RUST ON TOMATOES (D.).—The Tomatoes are attacked by the disease often called leaf-rust, due to the fungus *Cladosporium fulvum*. They should be sprayed with Bordeaux mixture, and the greatest care exercised with regard to the ventilation of the house. The disease is rarely troublesome where attention is paid to the maintenance of a free circulation of air and a fairly high temperature.

THREADWORMS (H. C.).—The long white thread-worms, reaching 2 inches or 3 inches or more in length, are in no way responsible for the trouble with your plants. They are really parasitic in the intestines of beetles and other large insects, leaving them at a certain stage, when they are found on the leaves of various plants and so on. The source of the trouble of which you complain must be sought elsewhere.

GOLD-FISH OUT OF DOORS (H. W.).—Gold-fish with standard ordinary writers in outdoor ponds in the South of

ROSE MRS. AMBROSE RICARDO, AWARDED A SILVER-GILT MEDAL AT THE NATIONAL ROSE SOCIETY'S EXHIBITION, SHOWN BY MESSRS. S. MCGREDY AND SON. (See page 17.)

England, but we have had no experience with them out of doors in the North. Perhaps it would be as well to place them indoors for the winter. Some people feed the fish with a little bread as well as with ants' eggs. It is difficult to say how often they require feeding, for that depends entirely on the amount of food material they find in the water. It would perhaps be advisable to give them quite a small quantity at once and feed them once a day.

NAMES OF PLANTS.—*H. J. Hemp.*—*Thalictrum flavum* and *T. minus*.—*F. J. H.*—*Spirea canescens*.—*C. L. Crawboll.*—*Campanula carpatica*; *Silene pendula*.—*A. G.*—1, *Cannot* name varieties of English Iris; 2, *Dianthus plumarius* variety; 3, *D. superbus*.—*W. G.*—1, *Specio* *Dore-nium*; 2, *Lathyrus niger*; 3, *Sedum rupestre*; 4, *S. altissimum*; 5, *Erodium Manescavi*; 6, *Geranium nodosum*.—*P. M.*—"*Denbigh*."—*Korria japonica* (type); *Hedysarum coronarium* (French Honey-suckle), best raised from seed in spring. —*M. J. P.*—1, *Iris dave-censis*; 2, *Campanula pusilla*.

SOCIETIES.

THE NATIONAL ROSE SOCIETY'S SHOW.

THE annual metropolitan exhibition in connection with the above society was held in the Royal Botanic Gardens, Regent's Park, on Friday of last week, and proved a great and unqualified success. The exhibitors numbered nearly three hundred, a record number. The arrangements, as usual, were excellent, and reflected the greatest credit on the courteous secretary, Mr. E. Mawley, and the members of the council.

NURSERYMEN'S CLASSES.

Both in quantity and quality the Roses displayed in the nurserymen's classes left nothing to be desired, providing further evidence, if such were needed, of the high standard of perfection that has now been reached in the art of Rose-growing. The classes for Roses in Excess and groups of Roses were alike well filled, the whole exhibit being one of unusual splendour. In Class 1 for sixty-two blooms, distinct, there were five competitors, all of them showing blooms in first-rate condition. The first prize (trophy and gold medal) went to Messrs. Benjamin B. Cant and Sons, Colechester, for perfect flowers in clean and fresh condition. Among the finest blooms were a new red seedling, *Augustus Hartmann*, The Lyon Rose, J. B. Clark, Frances C. Sison, Mrs. Edward Mawley, and Edward Mawley, Second, Messrs. A. Dickson and Sons, Limited, with wonderfully fine blooms of *Florence Pomber-ton*, the new red H. V. Maclin, Mrs. Muckellar and Elster; third, Messrs. Frank Cant and Co., Colechester, whose exhibit contained the best Hybrid Tea in a magnificent bloom of *George Dickson*, fourth, Messrs. B. Harkness and Co., Hrelan, with a fine lot, including Mrs. John Laing as the best Hybrid Perpetual.

Class 2, for forty distinct varieties, three blooms of each, was won by Messrs. Alex. Dickson and Sons, Limited, Hawthorn, Newtownards, with an admirable array of blooms, in which we noted *Mme. Jules Graveureux*, H. V. Maclin (*vivid crimson*), *Mabel Drew*, the new deep red Mrs. Conway Jones, Mrs. David McKee and Mrs. John Laing, the last named being shown in fine condition by many exhibitors. The second prize was won by Messrs. B. Cant and Sons, Colechester, who showed the Lyon Rose in wonderful colour; third, Messrs. Frank Cant and Co., Colechester.

Mr. George Prince, Longworth, gained the first prize and challenge cup for forty-eight blooms, distinct, in Class 3, his blooms of The Lyon Rose, *Marechal Niel* and *Mme. C. Souper* very much enhanced the rich colouring of his exhibit; second, Messrs. Perkins and Sons, Coventry; third, Messrs. G. and W. H. Burch, Peterborough.

For twenty-four blooms, distinct (Class 4), Messrs. Chaplin Brothers, Limited, Waltham Cross, were first with a nice lot, including good solid blooms of Hugh Dickson, Her Majesty and Komur Carolina. Second, Mr. W. E. Hammond, Burgess Hill, Sussex; third, Mr. John Mattock, Headington, Oxford.

There was keen competition for sixteen varieties, three blooms of each, the first prize going to the King's Aer Nursery Company, Hereford; second, Messrs. G. and W. H. Burch, Peterborough; third, Mr. W. H. Frettingham, Repton Nurseries, Nottingham.

For twelve white and twelve crimson Roses shown together, Messrs. Frank Cant and Co were first with the varieties *Fran Karl Druschki* and *Gloire de Chateau Gimmoussan*.

Mr. Walter Bentley, Belgrave, Leicester, was first for nine varieties of decorative Roses in vases. Particularly fine were *Mme. Souper*, *Duchess of Wellington* and *J. Hill*. Second, Messrs. Chaplin Brothers, Limited; third, Mr. L. J. Hicks, Twyford.

For eighteen decorative Roses in vases, the first prize was secured by Mr. J. Mattock, for an excellent collection, among which we noted *Edward Mawley* and *Lady Rossmore*. Mr. John Pigg of Royston was second for a superb collection, among which we observed *Rayon d'Or*, *Lady Hillington* and *Le Progrès*, the yellow tones prevailing.

There was a beautiful class for twelve varieties to be shown in vases (Class 9). This was won by Messrs. D. Prior and Sons, Colechester, whose vases of *Leshe Holland*, *Lady Ashdown*, *J. Hill* and *Bessie Brown* left nothing to be desired. Second, Messrs. A. Dickson and Sons, Limited, with an almost equally fine lot, including *Duchess of Portland*, *G. C. Wand* and *Mildred Grant* in the best of

condition. Third, Mr. G. Prince, who showed the little-known E. V. Hermanos (apricot) and Mrs. A. E. Coxhead (bright rosy red).

Mr. Henry Drew, Longworth, was a good first for sixteen Teas and Noisettes, his best blooms being Medea, W. R. Smith, Mme. Jules Graveraux and Mrs. Myles Kennedy. Second, Mr. G. Prince; third, Mr. J. Mattock.

For twelve Teas and Noisettes, Mr. John Mattock led the way, showing beautiful blooms of W. R. Smith and Mrs. Foley Hobbs. Second, Messrs. J. Burrell and Co., Cambridge; third, Mr. E. J. Hicks, W. R. Smith was shown well by most competitors in this class.

D'ombain Cup.—Considerable interest was centred in the class for the D'ombain Cup, awarded to the best twenty-four Teas and Noisettes. This was again won by that successful exhibitor Mr. G. Prince, who has won this cup ever since it was first offered. For the third year Mr. Drew, also of Longworth, was second. Third, Messrs. Benjamin R. Cant and Sons. Among the most beautiful Roses of this class were Miss Alice de Rothschild, Alexander Hill Gray, Mme. Constant Souperet, Maman Cochet, Mrs. Myles Kennedy and Margel Niel.

For thirty-six vases of decorative varieties, Mr. John Mattock was first, winning the A. G. Turner Cup with a grand lot, including the single Crimson Damask, Prince de Bulgarie, Chateau de Clos Vougeot, Lady Hillingdon and General Macarthur. Second, Messrs. Frank Cant and Co., who showed Rouge Angevine in great form. Third, Messrs. W. Spooner and Son, Woking.

Mr. Henry Drew was first for nine Teas and Noisettes, seven blooms of each, shown in vases. His vases of Mrs. Foley Hobbs, Miss Alice de Rothschild and Mrs. Hulbert Taylor were capital; so also were Harry Kirk and White Maman Cochet shown in the second prize collection by Messrs. D. Prior and Sons. Mr. G. Prince was third.

Mr. E. J. Hicks was first for a group of eighteen varieties of decorative Roses. His vases of American Pillar and Mme. Ravary were much admired. Second, Mr. E. Hicks, Wantage Road, Wallingford, Berks, who showed the singles Irish Elegance and Irish Glory in perfect form.

In a similar class for eighteen varieties Messrs. W. Spooner and Son were first with a fine lot of Ramblers, including the charming Rosa moschata alba. Second, Messrs. Frank Cant and Co., who showed Crimson Damask in wonderfully good form.

Messrs. Frank Cant and Co. led the way for twelve Polyantha Roses. Leonie Lamesch, after the colour of the Lyon Rose, was very telling. Second, Mr. G. Prince; third, Messrs. J. Burrell and Co.

Mr. E. J. Hicks was first for twelve wickurianas, followed by Messrs. Frank Cant and Co. and Mr. J. Pigg, the last named showing Diable, a fine single crimson. Lady Gohiva and Alberte Barbier were two of the best varieties in the class.

Messrs. J. Cocker and Sons, Aberdeen, were first for nine blooms of any new Rose with the superb Mr. Andrew Carnegie, of pale lemon yellow colour, and sweetly scented.

Messrs. Hobbies, Limited, gained first prize and a gold medal for a group of Roses occupying 250 square feet. Weeping standards were arranged over a groundwork of the best varieties in cultivation, with suspended baskets of such good varieties as Marquise de Sinety and Rayon d'Or in the foreground. Second, Messrs. Paul and Son, Cheshunt, Herts, for an extensive and beautifully-arranged group, in which ramblers and wickurianas were well represented. Third, Mr. A. J. Allen.

Mr. G. Prince was first for twelve blooms of new Roses, with grand blooms of Mrs. A. Hammond, Mrs. A. E. Coxhead and Ethel Malcom. Second, Messrs. Perkins and Sons, Coventry, who showed Lieutenant Chauré and Mabel Drew in good form. Third, Messrs. A. Dickson and Sons, Limited, who showed Leslie Holland in first-rate condition. It is a fine red that stands out well in the exhibition box.

Messrs. W. and J. Brown, Peterborough, were first for a group of cut Roses 33 feet by 3 feet, gaining the gold medal for the fourth time. It was a magnificent group, staged in a masterly way, the pillars of The Lyon Rose, Marquise de Sinety and Avoca being worthy of special mention. Mr. E. M. Bradley, Peterborough, was a good second. These two groups were among the most meritorious in the show.

Messrs. Jackman and Son were first in a similar class for cut blooms, followed by Mr. Karl Therkildsen, Old Southgate, N. Third, Messrs. Morse Brothers, Deben Nursery, Woodbridge.

Baskets of Roses.—Roses shown in baskets again afforded one of the most pleasing features of the exhibition. Messrs. Paul and Son were first for nine baskets, distinct. Lady Ashtown stands well, and made one of the best baskets, while Mme. Chateaux and Harry Kirk were also very fine. Mr. John Mattock was a good second, with Mr. Walter Eastle third, the last-named exhibitor showing a superb basket of the new decorative Hybrid Tea Cherry Page, of a wonderful cherry pink colour suffused with yellow at the base.

For five baskets, Messrs. Chaplin Brothers were first, showing The Lyon Rose and Duchess of Wellington, both in first-rate condition. Second, The King's Acre Nursery Company, Hereford; third, Messrs. R. Harkness and Co., Hitchin.

For a basket of Rayon d'Or, Mr. George Prince was an easy first, his blooms being of exquisite form and colour. He was also first for a basket of Mrs. Foley Hobbs.

A basket of the new Mrs. Andrew Carnegie gained a first prize for Messrs. J. Cocker and Sons.

AMATEURS.

In the amateurs' trophy class for thirty-six blooms, distinct varieties, there were no fewer than nine entries, each exhibitor, without exception, showing well.

A grand lot of blooms won first prize for Mr. Franklin Dennison, Cranford, Leamington Spa, the flowers being even, fresh and of splendid quality. The better blooms

to this superb exhibit were Mrs. James Welch, Oberhofgartner Terks, Gloire de C. Guinoiseau, Lady Barham, Mme. Jules Graveraux, Hugh Dickson, Mildred Grant, Mrs. W. J. Grant, White Maman Cochet, Horace Vermet, William Shean, Queen of Spain, J. B. Clark, Bessie Brown, Princess Mary Merteckersky, Mrs. Foley Hobbs, Mrs. John Bateman, Mabel Drew, Frau Karl Druschki, Mrs. John Laing, Dean Hole and Souvenir de Pierre Notting. A splendid second prize series of blooms was shown by Dr. T. E. Pallett, Earls Colne, Essex, who is to be congratulated in achieving so much. His best blooms were Mrs. Theodore Roosevelt, Avoca, Dr. O'Donel Browne, Frau Karl Druschki, Mildred Grant, J. B. Clark, Dean Hole and Mrs. John Laing. Third prize was secured by Mr. Eversfield, Denne Park, Horsham. Splendid blooms of J. B. Clark, Mrs. Arthur Coxhead, Frau Karl Druschki and Mildred Grant were very noticeable in a handsome series of blooms. Fourth prize was secured by the Rev. L. C. Chalmers-Hunt, William Rectory, Letchworth, Herts. A grand bloom of Mildred Grant was especially noteworthy in this fine exhibit.

The six exhibits in the class for twenty-four blooms, distinct varieties, made a brave show, good quality generally characterising the whole of the exhibits. Mr. Franklin Dennison in this class again led the way with a charming exhibit of attractive flowers. Mrs. James Welch, Florence Pemberton, Yvonne Vacherot, Mildred Grant, G. C. Waud, Horace Vermet, Mrs. John Bateman, Mabel Drew, Her Majesty and Bessie Brown were conspicuously good. As in the premier class, Dr. Pallett was placed second, securing this position with a beautiful lot of clean, highly-coloured blooms. Lieutenant Chauré, J. B. Clark, Mrs. A. E. Coxhead, Dean Hole, Mrs. John Laing and Dr. O'Donel Browne were all good. Third prize was won by Mr. T. Park, Askew Mill, Bedale, who had some excellent blooms on his stand.

No fewer than seven exhibits were forthcoming in the class for twelve tebles. This is always a most interesting class, and the competition in the present instance was very keen. Again Mr. Franklin Dennison excelled, leading the van with a grand lot of blooms. Those especially worthy of note were Mildred Grant, Queen of Spain, Mrs. John Laing, Florence Pemberton, Mme. Jules Graveraux, Francois Michelon, Bessie Brown, Alice Linsell and Mrs. Theodore Roosevelt. A less even lot of blooms placed Mr. Conway Jones, Hucelecote, Glos, second. Those deserving of mention were Lohengrin, Dr. O'Donel Browne, Hugh Dickson, Dean Hole, J. B. Clark, A. K. Williams and William Shean. Third prize was awarded to Mr. G. A. Hammond, Woodlands, Burgess Hill, who had several fine tebles.

Six boxes of nine blooms of any Rose except Tea or Noisette represented Class 40, the first prize in this class being offered by Messrs. Thomas Rivers and Son, Sawbridge-worth. In this case Dr. T. E. Pallett secured premier honours with superb examples of Avoca, the flowers having nothing to be desired. Second prize was awarded to Mr. Alexander Hill Gray, Beaulieu, Bath, with charming examples of Florence Pemberton and with the same variety Mr. Franklin Dennison was placed third. This was a splendid competition.

The Harkness Cup, offered for twelve blooms, distinct varieties, open to all amateurs, was secured by Dr. C. Lamplough, Kirkstall, Hants, who staged a splendid set including Frau Karl Druschki, White Maman Cochet, Mildred Grant and Avoca; Dr. T. E. Pallett, Earls Colne, Essex, and Mr. G. A. Hammond, Woodlands, Burgess Hill, following in order of merit.

The Hammond Cup, for six blooms of new Roses, distinct, open to all amateurs, was secured by Franklin Dennison, Esq., Cranford, Leamington, who showed Mrs. Coxhead, Alexander Gray, James Welch, Mrs. A. Hammond, Duke of Westminster and Mabel Drew in excellent form and finish; Mrs. Beville Fortescue, Maidenhead, closely following as second, and H. L. Welton, Esq., Sanderstead, Croydon, third.

The Challenge Trophy, for Tea and Noisette Roses, value 25 guineas, was secured by Mr. A. Hill Gray, Newbridge, Bath. Among the varieties shown were White Maman Cochet, Muriel Graham, Medea and L. M. Gray; Mr. E. E. Everfield secured second and Mrs. Beville Fortescue third.

The Prince Memorial Prize, offered for eight distinct varieties, three blooms of each, was also secured by the same exhibitors in the following order of merit: First, Mr. A. Hill Gray; second, Mr. E. E. Eversfield; third, Mrs. Beville Fortescue. The varieties shown in the first stand included Maman Cochet, Mrs. Foley Hobbs, Souvenir de Pierre Notting and W. R. Smith.

For seven distinct varieties of exhibition Roses, five blooms of each, to be staged in vases, Mr. E. E. Eversfield secured first with Frau Karl Druschki, Hugh Dickson, A. Coxhead, J. Laing, Lyon, Bessie Brown and Dean Hole. Mr. J. A. Hammond was a good second, and Mr. Conway Jones third.

PERPETUAL-FLOWERING DECORATIVE ROSES.

For three baskets of cut Roses in distinct varieties the Rev. J. H. Pemberton obtained first position, Mrs. Wightman taking second and H. V. Machin, Esq., third.

For seven distinct varieties in separate vases, seven stems in each vase, the Rev. J. H. Pemberton was again first, showing Lyon, Rayon d'Or, Léon Pain, Prince de Bulgarie, Lady Ashtown, J. Hill and Gustav Grünwald.

For eighteen decorative Roses, distinct varieties, not less than three nor more than twelve stems of each variety, Mr. H. V. Machin took the leading honours; the Rev. J. H. Pemberton followed, a good second.

For a table decoration consisting of single Roses and Rose foliage only, Mrs. E. M. Burnett, Westwood Road, Southampton, secured the highest place with a beautifully-arranged table of Irish Elegance. Mrs. P. P. Wood being

second, Mrs. J. W. Smith third and Miss J. B. Langton fourth.

For a table decoration of Roses (singles excepted), Miss M. West took first with a lovely-arranged table of Richmond; Mrs. G. C. Sawday, second; Mrs. A. Robinson, third; and Countess Olga Pontiatini, fourth.

SILVER MEDALS FOR BEST BLOOMS IN THE SHOW.

Nurserymen.—Best Rose other than Hybrid Tea, Tea or Noisette: Messrs. R. Harkness and Co., for Mrs. John Laing.

Best Hybrid Tea: Messrs. Frank Cant and Co., for George Dickson.

Best Tea or Noisette: Mr. G. Prince, for Mrs. Edward Mawley.

Amateurs.—Best Rose other than Hybrid Tea, Tea or Noisette: R. Foley Hobbs, for Horace Vermet.

Best Hybrid Tea: Dr. T. E. Pallett, for Avoca.

Best Tea or Noisette: C. C. Eversfield, for Mrs. Foley Hobbs.

OPEN TO GROWERS OF FEWER THAN 3,000 PLANTS.

Twenty-four blooms, distinct, tested the skill of growers in the leading class in this division. There were four excellent exhibits. First prize and Hobbies Cup were won by Mr. W. Onslow Times; second, Mr. W. Boyes; third, Mr. H. K. Darlington.

In the same division the other class was for nine blooms of any Rose except Tea or Noisette, and in this class there were five entrants for honours. In this contest Mr. W. Onslow Times, Hitchin, was placed in the leading position with an even series of blooms. Dean Hole, Mildred Grant, The Lyon, Lady Alice Stanley and A. K. Williams were his best blooms. Second prize went to Mr. W. Boyes, Middleton-on-the-Wolds, East Yorks, a splendid Edward Mawley standing out prominently. Third prize was won by Mr. H. R. Darlington, Park House, Potter's Bar. Marquise Litta and Mrs. Theodore Roosevelt were splendid in this exhibit.

There were seven entries in the class for nine blooms of any Rose except Tea or Noisette, the winner being found in Mr. Eversfield, Denne Park, Horsham, who had well-coloured examples of Dean Hole in good condition. Second prize was won by Mr. F. R. Biggleston, Jesmond, Puckle Lane, Canterbury, who had beautiful examples of Frau Karl Druschki. With Mildred Grant Mr. W. Onslow Times was placed third.

OPEN TO GROWERS OF FEWER THAN 2,000 PLANTS.

The leading class was for twenty-four blooms, distinct, and there were four entries, all in superb form. This was a competition for a piece of plate, value five guineas, offered by Messrs. B. Cant and Sons, Colchester. Premier honours rested with Captain W. Jarrett Thorpe, Gransmoor, Hucelecote, Gloucester, who staged a very fresh, clean exhibit. Superb examples of Mildred Grant, George Dickson, Mrs. Dudley Cross, Mrs. Foley Hobbs, G. C. Waud, Mrs. James Welch and Dean Hole were conspicuously good. A good exhibit from Mr. H. L. Welton, Waratah, Sanderstead, Croydon, was awarded second prize, and third prize was secured by Mr. Gulliver Speight, Market Harborough.

Class 44, for eighteen blooms distinct, was a good test of cultural skill, and there were again four entrants. In this instance the first prize was won by Mrs. E. Croft Murray, Perivale, Ryde, Isle of Wight, who had a rather uneven series—Dean Hole, Avoca, Colonel R. S. Williamson, William Shean and Mrs. John Laing. A more even lot won second prize for Mr. E. A. Govett, Holiday House, Sunningdale, who had several very charming specimen blooms—The Lyon Rose, Mrs. W. J. Grant, Dean Hole and Souvenir de Pierre Notting. Third prize was awarded to Mr. John Hart, Lochinvar, Little Heath, Potter's Bar, who had Hugh Dickson in fine condition.

In the class for six blooms of any Rose except Tea or Noisette there were eleven competitors, and the margin of difference in several cases was very narrow. First prize was won by Mr. Lewis S. Pawle with fine examples of Dean Hole. Mr. F. Crawley, Stockwood, Luton, was second with beautiful blooms of Mme. Melanie Souperet, and with Hugh Dickson. Mr. F. R. Cooke was adjudged third. This was a capital competition.

OPEN TO GROWERS OF FEWER THAN 1,000 PLANTS.

Eleven entries in the leading class for twelve blooms; distinct varieties, made an especially fine competition, the quality in some instances being exceptionally good. The first prize in this class was for the President's Silver Cup value five guineas. This was secured by Dr. Charles Lamplough, who, as usual, had a grand, even, heavy lot of blooms. They were as follows: Mrs. Foley Hobbs, Florence Pemberton, Mrs. T. Roosevelt, William Shean, Mildred Grant, Mrs. W. J. Grant, Frau Karl Druschki, J. B. Clark, Mme. Jules Graveraux, White Maman Cochet, The Lyon and another, Mr. Lewis S. Pawle, Beaconsfield, Bucks, was second, showing excellently well. Mrs. Theodore Roosevelt, Mildred Grant, Dean Hole and Mme. Constant Souperet were all good. Third prize was won by Mr. F. H. Cooke, Birch, Colchester, with a pretty series.

OPEN TO GROWERS OF FEWER THAN 750 PLANTS.

Again there were eleven stands in competition, and this in the leading class in this division for twelve blooms, distinct varieties. First prize was well won by Mr. Curcock Sawday, Beechfield, Weybridge, with a fresh, even lot of blooms. Mrs. Foley Hobbs, Mildred Grant, Mrs. James Welch, William Shean, Gloire de C. Guinoiseau, Mrs. J. Laing and Mrs. Myles Kennedy were his best flowers. Second prize was won by Mr. P. J. Davis, North Warners, Burgess Hill, good blooms of Mildred Grant and Mrs. Theodore Roosevelt being noteworthy. Third prize went to Mr. D. Davies, Witheridge, Beaconsfield, for a good series.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Cutting Delphinium Spikes.—Now that the flowers of this valuable decorative plant are going over, it will be found advisable to cut off the old spikes as soon as they have faded. By doing so it will encourage a second crop, which, although not so fine as the first, will be found of great value both for beautifying the garden and for cutting. A good watering at intervals during dry weather, and occasionally with weak liquid manure, will be found very beneficial.

A Shortage of Plums and Pears.—According to the monthly report just issued by the Board of Agriculture, the prospects for tree fruit have deteriorated considerably since the report issued a month ago was published. This is attributed to drought, which caused many fruits to fall prematurely, and to attacks by aphides, which have this year been particularly bad. Although in some places there are good crops of Apples, the yield as a whole is expected to be poor, while Plums and Pears are almost a failure.

A Charming Hardy Annual.—One of the most beautiful hardy annuals that we have flowering just now is *Clarkia elegans* Salmon Queen. This is grown as a broad edging to the kitchen garden path and forms almost a low hedge, the plants being about eighteen inches high. The double flowers, which are very freely produced, are a delightful shade of salmon pink. Near by we have *Scarlet Queen*, the flowers of which are salmon scarlet in colour. These two *Clarkias* ought to be grown wherever hardy flowers are appreciated.

The Spanish Broom.—Each year as this season comes round we are reminded of the glorious effects that are made by the judicious planting of *Spartium junceum*, or the Spanish Broom. The flowers are golden yellow, and this year it is flowering exceptionally well. It is not in the least fastidious in regard to soil, but it prefers a warm, sandy medium and does not object to a poor, stony one. In the early stages young plants should be stopped in order to produce bushy specimens, for when once the plants become leggy this cannot be rectified by pruning.

A New Chinese Lily.—Among the list of new garden plants just published in the *Kew Bulletin* appears a new species named *Lilium warleyense*, a handsome plant with a general resemblance to a fine form of *L. sutchuenense*. The stem is about four feet high, without bulbils. The flowers, twenty or more, are pendulous on slender pedicels about three inches across, orange red, with prominent chocolate spots, segments recurved. Without doubt this subject will prove a great acquisition as a garden plant, although we fail to see why a new Chinese species should take its specific name after an English garden. With garden varieties or hybrids this is quite another matter, but in the case of an introduced species the name becomes misleading.

A Valuable Decorative Phlox.—Few hardy plants are more attractive during late spring and early summer than the pale blue-flowered *Phlox divaricata* Laphamii, which is well worthy of a place in every garden. Now that the flowers are over, a number of young growths will be found upon the old flowering shoots. These make excellent cuttings, and should now be taken off and placed in sandy soil under a hand-light, when they will readily root and make good plants for putting out later. An excellent subject for mixing with them will be found in *Sedum spectabile*, which will come into flower after the *Phloxes*.

A Beautiful Flowering Sage.—Few herbaceous plants blossom for a longer period than *Salvia nemorosa*, and few plants are more conspicuous in a mixed border. A specimen which has been limited to a dozen growths branches to form a plant 3 feet or more in diameter by the time the first flowers open in early June, and from mid-June to mid-August it bears its bright bluish flowers freely. After the majority of the flowers have fallen there are still the reddish brown calyx lobes to look forward to, and these stand out well among surrounding flowers. As it grows in ordinary garden soil and is easily propagated by cuttings of young shoots in spring, it is a plant for everyone, and few people will be likely to find fault with it. Some know it as *S. virgata*.

The Double Opium Poppy.—For producing effective masses of colour in the pleasure grounds with a small amount of trouble it is doubtful if there is any annual to surpass the Poppy. The *Shirley Poppy* (*Papaver Rhæas*), the *Scarlet Poppy* (*P. commutatum* or *P. umbrosum*), and the *Opium Poppy* (*P. somniferum*) each has its respective admirers. A large group of the double *Opium Poppy* is just now providing a brilliant and imposing mass of colour at the south end of the Temperate House at Kew. Growing about three feet in height the large double flowers, in numerous rich and varied colours, are extremely showy. On the other side of the Pagoda vista, near the Flagstaff, a large patch of *P. commutatum* or *P. umbrosum*, with its scarlet and black flowers, is equally effective.

A Useful Plant for Shady Places.—The common *Tutsan*, or *Rose of Sharon* (*Hypericum calycinum*), is one of the best plants for growing beneath the shade of trees, for, although it grows quite well in the open, it succeeds equally well under trees, and keeps in good condition right to the trunk. Throughout the year it is green, and provides a good carpet; but during June and July, when bearing its large golden blossoms freely, it is specially pleasing. Providing the ground is dug over previous to planting, it requires little further preparation. The plants may then be divided and planted in small clumps 9 inches to 12 inches apart, autumn or early spring being a good season for the work. By cutting the plant over in March, plenty of vigorous young shoots may be obtained.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose Lady Hillingdon.—I am quite satisfied with Rose Lady Hillingdon. It flowers beautifully at Fribourg on strong and erect stems, and is of the finest orange apricot hue. Pharisæer is also an excellent Rose, very free-flowering and mildew-proof; the colour is of rather a salmon pink shade.—BARONNE A. DE GRAFFENRIED-VILLARS, Paris.

Statice in the Greenhouse.—The various shrubby species of Statice from the Canary Islands, and the garden forms emanating therefrom, have long been popular greenhouse plants, their pleasing blue flowers remaining fresh and bright for a long time. Some of the annual kinds, too, are very pretty, one of these, remarkable for its distinctness and beauty, being *S. Suworowii*, which was introduced from Turkestan about thirty years ago. The manner in which the spikes are disposed gives it a decidedly uncommon appearance. In colour the blossoms vary from white to pinkish mauve or lilac. The white form was recently given an award of merit by the Royal Horticultural Society. This Statice needs to be sown early in the year and potted on as the young plants require it. Good examples may be grown in 5-inch pots.—H. P.

Lilium giganteum.—This King of Lilies does not, I fear, receive the attention which its merits deserve, so that it is a pleasure to come across a specimen of it, which I did the other day in the garden of Mr. Charles Campbell, Cloverlea, Cramond Bridge, Midlothian. Mr. Campbell, who is a keen amateur, picked up two bulbs of this Lily six years ago at an auction sale for a few pence. He planted them in his garden, which lies on a sunny slope and is formed of deep loam. For five successive seasons the plants made little growth, and hope deferred had almost made the heart grow sick when to his surprise Mr. Campbell's patience has this season had its reward. The specimens are not very large, but the foliage and flowers are about the normal size. The larger specimen, with seven good blooms, stands 6 feet 3 inches high.—CHARLES COMFORT.

Dipladenia boliviensis.—This is one of the smallest-flowered of the Dipladenias, but in many features it is decidedly one of the best. In the first place, being a native of Bolivia, it will succeed under cooler treatment than those which come from warmer regions; next, it is far less liable to the attacks of mealy bug than they are, and even if the pests effect a lodgment, they are more

readily got rid of, owing to the leaves being smooth. In addition, it flowers for a long period, namely, through the summer and well on into the autumn. The blossoms of this *Dipladenia* are about a couple of inches in length and as much across, the colour being of the purest white, with a rich orange yellow throat, the contrast being very marked. This species, which was introduced by Richard Pearce of tuberous *Begonia* fame, first flowered in Messrs. Veitch's nursery at Chelsea in 1868. Given a warm greenhouse or intermediate structure, *D. boliviensis* can be well grown.—H. P.

Hybrid Primulas.—Under the title "Primula cockburniana and Its Hybrids" appears a short article in THE GARDEN for June 28, page 324, which is most interesting, as it touches on a race of plants that are practically in their infancy; nevertheless, they have a great future in store. Here we have been crossing them since their introduction, and have planted some hundreds of crosses annually, which on blooming have been nothing

A FLOWERING SPRAY OF DAVIDIA INVOLUCRATA, A NEW HARDY TREE FROM CHINA

more than the type, and it is on experience that these Primulas do not cross freely. Among several good hybrids that have appeared here, one especially bears great promise. It is a cross between *P. bulleyana* and *P. cockburniana*, the first named being the seed-bearer. The colour is a shade of salmon, toning to yellow in the centre. The plant, blooming for the first time this season, has borne twenty-one good stems of blooms. One stem has thrown two adventitious stems from just below the bottom whorl of bloom, and two other stems one each. These side stems carried two whorls each, and the main stems from four to six each, which were rather closely set together and gave the plant an extraordinarily floriferous appearance. It is gratifying to note that *P. × Excelsior* is perennial, and it is probable that the work of evolution may have a great bearing in this direction.—D. LEWIS, Tolley Hall Gardens, Sheffield.

Rose Mrs. George Norwood.—In your issue of last week, under "New Roses" at the National Rose Society's Show, I note you have my seedling, Mrs. George Norwood, down as grown under glass. It was grown outside, and it was no fault of mine if the cards were placed wrong.—ELISHA J. HICKS.

Davidia Flowering at Norwich.—I think your readers may be interested to hear that a *Davidia* here has borne twenty-one inflorescences; not enough for a great effect, but sufficient to give one great hopes for its future as an ornamental tree in this country.—J. A. CHRISTIE, The Manor House, Framingham Pigot, Norwich.

Cypripedium Calceolus.—The English Lady's Slipper is one of the best of the race of hardy Cypripediums, and I saw recently an illustration of how enduring it is under the most adverse circumstances. In going through the magnificent gardens of the Marquis of Ailsa at Culzean Castle, Ayrshire, the other day, Mr. R. G. Hepburn, the gardener, drew my attention to some plants of *C. Calceolus* in flower in an opening in a thicket of one of the taller Polygonums. These plants were in the garden when Mr. Hepburn took over his appointment about two years ago, but were crowded up and hidden by the growths of the tall Polygonum. Room was made for them by clearing away some of these and opening them up to the light, with the result that they are doing well. This is a striking example of the ease with which *C. Calceolus* will withstand the most adverse conditions.—S. ARNOTT.

A Deteriorated Duke of Edinburgh Rose.

The following incident, which I have lately learned, may be of interest to those readers of THE GARDEN who pay special attention to Roses. A gentleman living near here bought and had planted in his garden about fifteen years ago a plant of the above Rose. It flourished and for many years yielded its usual bright scarlet-coloured flowers; but in course of time it began to bear, and does still, flowers of a pink shade, the centre a deeper pink than the outside. The plant is about six feet to seven feet in height and four feet to five feet across. I was told it had never been pruned during the fifteen years, but had had on one or two occasions just a piece or two of growth cut away. This item of Rose news seems to me so out of the ordinary that I venture to ask three questions, which perhaps some Rose authority will kindly deal with: (1) Was pink the colour of either or both of the parents of the above-mentioned Rose? (2) Did change and deterioration set in as a result of neglect or pruning? (3) Is it common for deteriorating Roses to change in colour? I thought they changed only in quality and form.—C. T., Highgate.

Blue-Flowered Hydrangeas. On page 323, issue June 28, "H. P." has a very interesting note on these popular plants. It is quite true that when certain preparations are applied to the soil, blue flowers result. I have had some considerable experience with blue-flowered Hydrangeas, having had specimens 7 feet through bearing dozens of blue-flowered heads, a few of the largest measuring nearly eighteen inches across. Undoubtedly there was iron in the soil, but the water was very "hard," and was conveyed to the gardens through pipes, being forced up to tanks from a pond which was filled by a stream, water trickling into it from bog and peat land on both sides. Stones on which water dripped from the pipe taps were soon coloured red. For more than ten years the flowers never failed to open blue, but on a few of the plants pink flowers developed as well as blue ones, and consistently so every year. I cannot understand why this should be. The blue flowers were as deep as Cornflowers.—G. G.

Habranthus pratensis in Scotland.—It is pleasant to come across the handsome flowers of *Habranthus pratensis* in a Scottish garden in the open border. This was the case the other day, when the writer observed this *Habranthus* flowering bravely in one of the borders in the famous gardens of Culzean Castle, Ayrshire, the seat of the Marquis of Ailsa. There was a good clump, which has been established for several years, and another one was present in another border. There were a considerable number of bulbs, bearing quite freely the handsome, trumpet-shaped, bright scarlet, Amaryllis-like flowers. This plant has acquired considerable prominence of late, largely through its exhibition at some of the London shows, where it has been greatly admired. Its success at Culzean, although this garden is highly favoured in the matter of climate, should encourage its cultivation. It is splendidly grown in some of the Eastern and Southern Counties of England, and as a hardy bulb it is worth attempting in the warmer parts of the north of the three kingdoms as well. It is properly called *Hippeastrum pratense*, but *Habranthus pratensis* is still its best-known appellation. It should be planted from 4 inches to 6 inches deep.—S. ARNOTT.

Dwarf Plants of *Solanum Wendlandii*.—Those who know this *Solanum* only as a vigorous-growing climber are surprised at the way in which it can be successfully grown as dwarf plants, each carrying a large head of its pretty lilac-coloured blossoms. A number of splendid examples were noted at the Holland House Show, and numerous were the enquiries as to how they were obtained. Such plants are really propagated from eyes put in early in February, and treated just as Grape Vines are. They are inserted singly into small pots, and plunged in a gentle bottom-heat. Under these conditions they soon start into growth, and are shifted into larger pots when necessary. During the earlier stages a temperature of 60° to 70° is maintained, but as the plants make headway a warm greenhouse is sufficient for them, as if kept in too high a temperature they run up weakly. Six-inch pots are large enough for the strongest examples.—H. P.

FORTHCOMING EVENTS.

July 23.—Flower Shows at Cardiff (two days), Sevenoaks, and Leamington (two days).

July 24.—Flower Shows at Exning, Roehampton and Romsey.

July 25.—Cheadle and Cheadle Heath Show (two days).

July 26.—Fife and Kinross Show.

THE ROSE GARDEN.

ABOUT GARDEN ROSES.

THERE is no time like the present for discussing the merits of garden Roses. One thing is very evident, viz., that the Roses we cherish as our best things in the North are by no means as satisfactory in the South.

The stronger soils and greater moisture in the North certainly favour many Roses that are robust, while the lighter and drier Southern lands are favourable to weaker constitutions. The idea of the Rose General MacArthur being subject to mildew, for instance, makes us open our eyes in amazement, such a thing being unknown in moister climates. Then, again, Lyon Rose is with us so specially liable to that pest, as well as so straggling in habit, that I should never admit it in any Rose garden, though for the sake of its lovely cut blooms I might grant it a lonely corner near the kitchen garden.

I see little mention of the brilliant George C Wand, which is such a welcome addition, as is also Commandant Felix Faure, an admirable red Rose that never seems mentioned as one of the specially desirable Roses to plant. The dwarf and beautiful Château de Clos Vougeot has hardly yet been sufficiently tried in the North, while in the South its praises are sung already. More important, perhaps, in the North than in the South is the freedom of the autumn bloom, and that is a factor in our choice of some importance. When I see such a Rose as Dr. O'Donel Browne mentioned as a desirable Rose, I feel seized with a wild desire to see that fairy place where it is beautiful as well as vigorous. While the grand old Rose Baronne de Prévois is still in existence, as I hope and believe it is, why grow such a coarse and inferior copy? I really think the blooms at an exhibition are so misleading to the innocent and ignorant amateur that now and again a note of warning is needed.

I often see those two good wichuraiana hybrids Gardemia and Alberic Barbier mentioned as equally good. In the hand perhaps they may be, but Gardemia flowers only once and grows so rampantly that Alberic Barbier, with less excessive vigour and (with me) absolutely continuous blooming qualities, never gets its due share of praise. I think there is a little secret that can be gained by careful observation of its growth and in the way the annual thinning out of the weaker shoots that have flowered is carried out; but I can affirm that not in one or two gardens only, Alberic Barbier flowers continuously from May to the end of October, the only Rose of that breed that is truly perpetual. Indeed, like Dean Hole, who said that "if for some offence I were only allowed to grow one Rose, I think I should nowadays choose Alberic Barbier" rather than the Gloire de Dijon, which he then considered the most perpetual of all Roses.

In the North neither Grüss nor Mme. Alfred Carrière flowers with the same certainty and profusion as in the South, while it seems to me that Dorothy Perkins and her two sports Lady Godiva and White Dorothy have found the secret of constant and late autumnal blooming, a thing much to be praised. The hardiness and vigour of the pernetiana Rose Juliet have been an agreeable surprise, and the blooms this year are even beautiful in the North, so we hope for useful developments in this strain.

Of the single Roses, none, it seems to me, can compare with Irish Elegance, both as a bush and for cutting purposes, and this Rose is as yet too

little known and grown in the North. Some day I hope to hear how that fine Hybrid Tea Mary Countess of Ilchester behaves in English gardens. In the South of France it has proved the finest, sweetest and most lasting of all Roses, so that if it proves ultimately a good winter bloomer it will be a great addition to any Rose garden.

EDWARD H. WOODALL.

ROSE EDWARD MAWLEY.

The present season has particularly suited this grand Rose. With me it has been by far the best red Hybrid Tea in the garden, surpassing even that grand variety Leshe Holland. I am particularly glad Edward Mawley is turning out so fine, for it bears such an honoured name that all rosarians wish it to be worthy of it. I am convinced it is going to be one of the best crimson garden Roses, and will be specially beautiful in a cool season and also in autumn. It is almost certain to me that Mme. Melane Souper was the seed parent of this Rose, crossed possibly with Etoile de France. I am hoping that by using a more double flower, such as George Dickson, as seed parent we may produce a good double bright scarlet Hybrid Tea, a colour still wanting among this class of really good exhibition standard.

The Portadown Roses are proving themselves to be valuable acquisitions; particularly the recent varieties. I cannot get myself to admire His Majesty, but can well believe in Ireland and in some other parts it will come fine at times; indeed, I have had occasional blooms of superb form. I hope Messrs. McGrody and Son will continue to provide us with novelties of the high standard they are now doing, and I am looking forward keenly to the quartet they are putting on the market this year.

DANECROFT.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Cabbages for Spring.—Notwithstanding the fact that we are just in the flush of the Green Pea season, it behoves us to give consideration to the Cabbages which will assuredly be wanted next spring. The Green Peas satisfy us now, but they will not do so then, and in the spring months there is nothing sweeter than a freshly-cut Cabbage, and probably nothing healthier, either. At least two sowings of seeds ought to be made in every garden, as there must not be such a thing as failure. The end of the third week of the month is an excellent time in most seasons; but should the autumn prove mild and particularly favourable to progress, there is a decided chance that these plants will be too soft to stand the varied weather of the winter. To be on the safe side, sow again approximately three weeks later, and there is little danger that the result of both sowings will be failure. Thin sowing, early thinning and prompt transplantation are essential to success. Although it has been in commerce so many years, I have yet to find the variety to beat Flower of Spring in any season, soil or district.

Winter Greens.—The planting out of the different members of the Cabbage family to produce fresh green vegetables during the winter months is now in active progress, and the opportunity of a favourable day ought never to be missed. One cannot, of course, question the desirability of planting when the weather is showery and the soil

pleasantly moist, because the plants do not then experience the smallest check; but waiting beyond a reasonable time has nothing to commend it. Given strong, splendidly-rooted plants, there is no fear of loss, even though the conditions are not ideal. When it is decided that there shall be no further waiting, water the ground, or the stations, heavily in the morning and plant late in the evening of the same day, soaking afterwards as may be needed.

Potatoes.—The early Potatoes are coming out most satisfactorily up to now, and those who have been buying imported stuff will be appreciating the immense superiority of tubers dug from their own gardens and cooked within a couple of hours. The final earthing of the main crop and late varieties is imminent, and before it is done every plot should be sprayed with Bordeaux or Burgundy mixture as a preventive of the disease. Many people still labour under the erroneous impression that spraying does not pay. In a year like 1911,

encourage the plants to continue the production of flowers. See that the soil is maintained pleasantly moist at the roots, loosen the surface with hoe or fork, and spread a thick mulching of manure along each side of the rows. Water through this, and do not forget heavy hosing on the evenings of hot, dry days.

ROCK AND WATER GARDEN.

STONE EDGINGS IN THE KITCHEN GARDEN.

THE stone edgings to the walks shown in the accompanying illustration took the place, some eighteen months ago, of grass verges, and when first completed and before the planting had time to be effective, varying opinions existed as to which was the more attractive. Now that the various plants have had time

equally as good an effect could be produced with winding or curved paths and of irregular widths. The walks in the kitchen garden here run north and south, east and west, and though large pieces of rock do not exist to form shade, positions may be found to suit almost all plants, and the taller herbaceous plants, with the pyramid fruit trees at the back, assist in producing shaded positions. Where it is desirable to include rock and alpine plants, and a rockery proper does not exist or a suitable place cannot be found to build one, then the present idea is worth consideration, as the plants are always easily examined, and watering, damping, cleaning and top-dressing may be carried out in the most expeditious manner.

The number of plants that may be utilised is really surprising, also the quantity needed to plant it. The first season the commoner subjects were planted lavishly to produce an immediate effect; but these grew generally with such remarkable vigour that last autumn and in the early spring

STONE EDGINGS TO THE KITCHEN GARDEN PATH AT ALDENHAM HOUSE, ELSTREE.

when we had continuous drought until well on in summer, it is possible that there is a waste of time and material; but we never know what the weather is going to be, and those who consistently spray twice—once at the middle of July and a second time three or so weeks later, according to the weather—will find that, taking one season with another, spraying will pay splendidly. A spraying syringe answers admirably where the area to be dressed is limited.

Tomatoes.—The plants indoors will be demanding abundant supplies of water, and probably of liquid manure, and any neglect will be paid for in loss of crop. There is no doubt that the smaller, wicker reason, the receptacle containing the roots, the better. The thrifty plant is short-jointed, sets its crop splendidly, and when the necessity for it arises, feeding can easily be done.

Green Peas.—It is imperative that the pods of these shall be gathered as closely as possible, to

to become established—and quite a host of subjects are included—it is unanimously declared to be a fine feature. These rock edgings to the paths may be constructed at very little cost, the stone being the greatest item, and if economically placed, some good, large spaces may be provided for the stronger-growing subjects, which create a fine effect when seen in masses; and, with very little trouble, the natural soil and drainage, if not altogether suitable, may be improved. The stone used here was fairly flattish sandstone, which needs to be truly embedded, and, if possible, some good soil added to provide a good rooting medium underneath as well as between the crevices. Pockets may be formed of varying sizes, some on a level with the walk, others slightly raised. Generally, we used two tiers of stone, and though our walks are perfectly straight and the width even throughout, the broken-up edging of stone seems quite in order, and it is evident that

stringent measures had to be taken to reduce them and substitute better-class plants. Annuals in our case are left out entirely, and only a few of the dwarfest and best rock shrubs included, the *Helianthemum* in variety making fine patches of colour in the sunniest spots. The smaller plants of less vigorous habit are grouped together in small colonies in well-drained soil, so that they do not become so readily neglected and lost as they might be if isolated. The names of a few subjects that have done particularly well with us may not be out of place. The following are in flower now: *Saponaria ocyroides*, *Achillea rupestris*, *A. tomentosa*, *Saxifraga Cotyledon*, *S. pedatifolia*, *S. aizoon recta*, *Campanula carpatica*, *Veronica prostrata*, *Armeria maritima alba*, *A. lauchiana*, *Viola gracilis*, *V. bosniaca*, *V. papilio*, *Phlox pilosa*, *Dianthus Napoleon III.*, *D. Duchess of Fife*, *D. superbus*, *D. fragrans*, *Primula japonica*, *P. pulverulenta*, *Gypsophila repens rosea*, *G. prostrata*, *Achillea serbica*, *Dianthus caesus grandiflorus*, *Geranium lancastriense*, *Ernus alpinus*, *Aubrietia tauricola*, *Potentilla Miss Willmott*, *Hutchinsia alpina*, *Linaria alpina rosea*, *Oenothera*

ovata, *O. taraxifolia* and *Campanula G. F. Wilson*. Other subjects that have been particularly fine are *Aubrietia Lavender*, *A. Moerhousii*, *A. J. S. Baker* (the earliest to flower), *Erysimum pulchellum*, *Ranunculus montanus*, *Saxifraga bathoniensis*, *S. Stansfieldii*, *S. Camosii* and *Veronica repens*. The foregoing are just a few of the more vigorous growing and those that have established themselves freely and flowered profusely. A few of the choicer plants that appear to be doing well are *Dianthus neglectus*, *D. alpinus magnificus*, *Campanula muralis*, *C. Zoysii*, *C. Elatines*, *C. Profusion*, *Morisia hypogaea*, *Achillea Kellereri*, *Oxalis enneaphylla*, *Potentilla pygmaea*, *Geranium argenteum*, *Geum montanum*, *Gentiana verna*, *Linaria concolor*, *Soldanella minima alba*, *Wahlenbergia vinctiflora*, *Pentstemon pygmaea*, *Phlox Douglasii*, *Viola pedata bicolor*, *V. glabella* and *Asperula suberosa*.

E. BECKETT.

THREE BEAUTIFUL CROCUSES.

Yellow : *C. chrysanthus* E. A. Bowles. Mauve : *C. Sieberi*. Purple & Buff : *C. Imperati*.

**COLOURED PLATE.
PLATE 1474.**

SPRING CROCUSES.

THE triumvirate of beautiful Crocuses so well shown in the coloured plate presented with this issue recall one of this season's spring shows at Vincent Square, when these flowers were shown by Messrs. Barr. I noted at the time how delightfully their colourings blended, and was delighted when, some time later, I was shown the clever portraits by which they had been immortalised. Among really good gardeners by far too few give due place to the early-flowering spring species of *Crocus*. Anything that will flower in January and February in our climate is of value; but when it possesses beauty and fragrance, as well as precocity, it deserves honour and attention. The garden cannot be worth digging in that will not provide enough sunny nooks for a dozen or so clumps of early Crocuses, for not only chone ledges of the rock garden backed by a heat-radiating stone, but also a bare spot at the foot of some deciduous shrub, or large-leaved herbaceous plant that must be placed well away from neighbours, is admirably suited for spring Crocuses. I find the mixed borders are wonderfully brightened at the dull time of the year if groups of twenty to fifty *Crocus* roots are planted round such plants, especially towards the back of the beds, where I notice that sparrows do not pull them to bits quite so badly as when they are closer to the edge of the bed.

Two of the species shown in the coloured plate are well suited for this manner of planting — *Imperati* and *Sieberi* — and both of them, in an ordinary season, should be bright with flowers before January is over. Being inexpensive, they should be planted freely, and if allowed to seed will soon spread. The form of *Imperati* shown is rather exceptional in the lack of purple featherings on the buff outside of the outer segments, and is, perhaps, not so beautiful as the more ordinary form in which the featherings are well marked. *C. Imperati* varies endlessly in this respect, and is one of the very few Crocuses in which markings change from season to season. I raised a number of seedlings of it and selected some very distinct forms and grouped them in the rock garden, but the next season I was horribly disappointed to find my patch of self-coloured buff ones were as striped, mottled and ring-straked as Jacob's variegated flock of sheep, while one special beauty I had selected for its wide crimson featherings was scarcely striped at all. I have noticed the same tendency to seasonal variation in seedlings of *C. versicolor*, but am thankful to say all others that I know remain constant.

C. Imperati is generally collected from the neighbourhood of Naples, and varies very much, beautiful white forms occurring sparingly, some without external feathering, and others as heavily marked as the typical form with lilac ground colour. From this latter form I have raised some very pretty pale-coloured seedlings, which are remarkably robust and large flowered. The

unfeathered white forms appear to breed true when self-fertilised, as do so many true albinos, and are most likely Mendelian recessives.

C. Sieberi comes from Greece, but yet is a hardy and robust species. It has a coarsely-reticulated corm tunic, and does not seem to be so palatable to mice as some of the species with thinner coats. Its colour is a delightfully cool shade of lilac. A very bright orange throat and rich scarlet stigmata greatly add to its beauty.

There is a richly-coloured form of *C. Sieberi* sometimes sold as *C. atticus* and also as *C. Sieberi purpureus*, but the gem of this species is the form

unless the Balkan Question can be speedily settled and Crete become a more law-abiding country.

The last of these Three Graces is one of the greatest acquisitions to our list of spring-flowering bulbs. It is one of a set of seedlings raised at Haarlem in Messrs. C. G. van Tubergen's Zwanenberg nursery. Mr. John Hoog of that firm kindly sent me blooms of this race some years ago, and my delight in their beauty ended in his generously sending me corms of them and naming the one here shown after me. They are a remarkable break in this very variable species, being quite three times as large as wild forms, but retaining all the good characters of the species. As may easily be seen from the drawing, the Gourd shape of the flowers of *C. chrysanthus* is not spoiled by the increase of size, and the soft sulphur yellow of its mother (the var. *pallidus* from the Bithynian Olympus) has been inherited by the babe, with the addition of a richer tone of brown madder markings at the throat. I wish I possessed the vigour and good temper of this my namesake! I know no other Crocus of the annulate section that looks so happy and smiles back at the winter sun so radiantly. Although the July air is sweet with Roses and Honeysuckle, Lavender and Lilies, it is not too soon for me to sound a note of warning that all this will pass away and January days come again, with nothing better for the nose than the wet leaves and moss in the woods, and then if you have tucked away a few plump corms of these early Crocuses in suitable nooks, not later than September, I know you will bless me when a few blooms brighten the brown earth or a tightly-rolled bud is brought into the warm room and, bursting open, gives out that mixed fragrance of Primroses, honey and saffron that seems to epitomise spring itself and may always be found in a young bloom of any of these three forms of *Crocus*.
E. A. BOWLES.

OSTROWSKIA MAGNIFICA, AN ADMIRABLE PLANT FOR A WARM CORNER.

FLOWER GARDEN.

A HANDSOME BORDER FLOWER.

(*OSTROWSKIA MAGNIFICA*.)

THIS really fine, though somewhat tender plant is seldom seen as a border flower, owing to difficulties in its culture. It requires very sandy soil in full sun, and it is worth noting that it is more often killed by damp than by hard weather. Now and then one sees cut blooms of the beautiful *Ostrowskia* at flower shows. Such blooms are invariably grown by expert plantsmen, who give this plant special treatment. The tubercous root is exceedingly brittle, and must be handled with care. In ordinary soil a hole should be made with a crowbar at least 2 feet deep and filled with sharp silver sand, leaving the crown of the plant 3 inches under the surface. In winter, protection by means of dry litter will be found beneficial. The flowers, mauve in colour, resemble those of a huge *Campnula*, to which genus it is a near relative. This is the only species of *Ostrowskia* known to science. It was introduced from Central Asia in 1887, and is named in honour of the Russian botanist Ostrowski.

known as *C. Sieberi versicolor*. It comes from Crete, and has not been collected for some years owing to the disturbed state of that island and the evil reputation for bandits of its mountains. In this variety the ground colour is a glistening white, the orange throat and scarlet stigmata being even more conspicuous than in the type form; but its chief charm lies in the markings of the outer segments, which vary much in size and shape, and are of a rich crimson purple which contrasts vividly with the whit and orange. It is rather curious that although the stigmata are unusually large in these forms, they are very shy seeders, and so are likely to remain scarce in gardens for many years

IRIS SIBIRICA AND ITS GROUP.

IRIS SIBIRICA is a moisture-loving species, and though it will do well on a border, it is never so fine as when grown so near to water that its roots may enter therein. There are many forms of this species, but a good selection of the common blue is, I believe, the most effective. Messrs. Barr and Sons have a kind they call Blue King, and this, no doubt, is good.

A GLIMPSE OF THE IRIS GARDEN AT CLANDON PARK, SURREY.

The cultivation of *Iris sibirica* presents no difficulty. It divides easily, and may readily be raised from seed. Division and replanting should be effected immediately after flowering. The recognised varieties of this species are few, and are not of botanical consequence. A narrow-leaved form is known as *angustifolia*, a form with stiffly erect, sharp-pointed leaves and pale blue and white

flowers is known as *acuta*, and another with white flowers, the segments of which are crisped, is the *I. flexuosa* of the *Botanical Magazine*, t. 1163. The variety *orientalis*, which is botanically distinct, Mr. Rickatson Dykes has constituted a distinct species, and I have no doubt he is right. While the pedicels of *I. sibirica* are of unequal length, and some very long, the capsules short and globose, and the seeds flat and D-shaped, *I. orientalis* has the pedicels of more equal length, the capsules longer and trigonal and the seeds thick and cubical. There

is a good figure in Mr. Rickatson Dykes' "The Genus *Iris*." To this species belongs the ornamental form known as Snow Queen.

The group of *I. sibirica* is beardless and rhizomatous, with linear leaves, and may practically be recognised by having a hollow stem. Mr. Dykes, however, includes two with solid stems—*I. Clarkei*, a handsome ally of the hollow-stemmed *I. Delavayi*, with purple-violet flowers, the falls with gold at the base and white variegation just above, which has been classed with the *Pseud-evansias*, and tends to possess a crest and rudimentary beard, and *I. prismatica*, which has a reduced or nearly obsolete perianth and standards only one-sixth of an inch broad. This is not ornamental. It can be confused with no other, though, by its small standards, it recalls *I. setosa* and *I. Hookeri*. Both these differ by having sword-shaped leaves—in the case of the first green, and in the case of the latter glaucescent. Of the remaining five species in this group all are new, with the exception of *I. Delavayi*, three described by Mr. Dykes, and one, *I.*

Wilsoni, by Mr. C. Wright. For the present purpose we may note them as follows, according to the striking feature of colour:

I. Delavayi (Micheb).—This has falls of deep violet blue colour with white streaks, the standards erect, of paler violet colour. In my experience this plant has been disappointing; it has not flowered freely, and it has twice died out in the

very position it ought to have liked. It has a stout, creeping rootstock, with leaves 2 feet to 2½ feet long by half an inch to two-thirds of an inch broad. They are erect and strongly ribbed. The peduncle is longer than the leaves, the spathes are 2 inches to 2½ inches long, lanceolate, green, with scarios tips, and the pedicels are of the same length. The flowers are 2 inches to 2½ inches across, the tube half an inch long. The fruit is sharply angled, and about four times as long as broad. A figure will be found in the *Botanical Magazine*, 1899, t. 7661. It is native of the marshes of Yunnan.

I. Bulleyana (Dykes).—This is an ally of *I. Clarkei*, with standards of blue-purple, and falls mottled with the same colour on a creamy ground. From *I. Clarkei* this is easily distinguished by its hollow stem; the rhizome is slender, widely creeping; leaves ensiform, shining above, glaucescent below; stem about a foot high; spathes two-flowered; valves green, acute. This is native of China, and probably came from the province of Yunnan. It is, so far, doing well in the Cambridge Botanic Garden in a moderately moist bed of the bog garden.

I. Forresti (Dykes).—This is a lovely yellow-flowered species, and it is distinguished from the older *I. Wilsoni* by having pedicels which do not exceed an inch in length. The leaves, too, are narrow and grassy, with polished upper surface and glaucescent under surface, while those of *I. Wilsoni* are more like those of the Oriental forms of *I. sibirica*. It is distinctly an acquisition. The rhizome is slender; the leaves linear, about a foot long and a quarter of an inch broad; the stem leafy, and about a foot high; spathes one or two-flowered, green, acute, and 2 inches or 3 inches long; the tube is broad, half an inch long; falls oblong-cuneate; the blades almost vertical and of very obtuse aspect in the Cambridge plant; the claw veined, with brown standards, oblong lanceolate; crests quadrate. This was found in open mountain meadows on the eastern flank of the Lichiang Range in North-West Yunnan. It appears to do well in the Cambridge Botanic Garden, planted in the bog garden in a bed that is moist but not wet.

I. Wilsoni (C. H. Wright).—This is of yellow colour, the falls pale yellow, marked on the lower half with purple veins. In the case of *I. Forresti* flowered at Cambridge marking was slight, and consisted of dots in lines rather than distinct veins. The rhizome is shortly creeping; leaves linear acuminate, about two feet long and about one-third of an inch wide, basid and minutely scabrid; the scape is only a third as long as the leaves; spathes green, broadly lanceolate acuminate, 3½ inches long; pedicels 2½ inches to 4 inches long; tube green, about one-third of an inch long; falls 2 inches long and three-quarters of an inch broad, pale yellow, marked with purple veins in the lower half; standards erect, oblong lanceolate, about one and a-half inches long and one-third of an inch broad, yellow; filaments yellow; anthers white; style branches yellow; crests obtuse, closely denticulate. A figure of the type is given in the *Botanical Magazine*, 1910, t. 8340. The variety *major* has shorter pedicels, a perianth tube half as long again, longer and broader falls, standards of the same length but narrower, longer ovary, purple-marked filaments and with style arms pale brown at the midrib and towards the apex. This species was discovered by Mr. E. H. Wilson in Western Hupeh, growing in grasslands near Tang Hsien at about seven thousand feet above

sea-level. It was collected for Messrs. James Veitch and Sons.

I. chrysographes (Dykes). The flowers of this plant are of the richest dark red-purple, velvety in texture, with central and broken flanking lines of gold. It is undoubtedly a very fine plant, and was originally raised by Miss Willmott in her garden at Warley Place, Essex. The falls are 3 inches long, and the blades, which are twice as long as the hilt, droop almost perpendicularly. The flanges on each side of the hilt are marked with gold on a red-purple ground. The standards are long and narrow, poised at an angle of about 45°, and point outwards as in Clark and Delavay. According to the figure in the *Botanical Magazine*, 1912, t. 8433, they are

I. Forresti and *I. chrysographes* strike me as very valuable new plants. The particulars here given of all the new species I have taken chiefly from the original descriptions.

Botanic Garden, Cambridge. R. IRWIN LYNCH.

SIBERIAN IRISES AT CLANDON PARK.

Irises in varied and rich tones of colour form the chief feature in summer in the Earl of Onslow's garden at Clandon Park, Surrey. An immense border, stretching along the lakeside, is filled with Irises from end to end, creating a scene of unspeakable splendour at flowering-time. *I. sibirica*

are about eighteen inches higher than *I. Kampteri*, and are planted in heavy, loamy soil approaching clay; in fact, the roots penetrate into clay, and in this they thrive and flower for quite a long period. It is most essential that the seed pods be cut off immediately after flowering, or the plants will suffer and not be as strong for the next season's flowering. *I. sibirica alba maxima* does well here; so also does *I. sibirica Snow Queen*. These two, to my mind, are by far the best of the whites; the former is the taller of the two, has a greater abundance of flowers, and is more graceful. *Snow Queen* is much the larger flower, and a more pure white. The stems of this variety are not as tall as *I. sibirica alba*, but the purity and size of the

IRIS SIBIRICA BY THE LAKESIDE AT KEW.

narrowly spoon-shaped. The stems are apparently one-headed, from 15 inches to 18 inches long, and bear one or two reduced leaves. They are less hollow than those of *I. sibirica*. The leaves are linear, about half an inch or less in width, and 15 inches to 18 inches long. They curve gracefully outwards, so that the flowers rise well above them. This is one of the finest of Irises, and is very floriferous. With Mr. Dykes plants flowering for the first time produced four or six flower-stems. It is native of Western Szechuan in China, and was found by Mr. E. H. Wilson growing in thickets near Kuan Hsien— from 7,000 feet to 11,000 feet above sea-level.

and its varieties are there in magnificent clumps, and in writing of these Mr. H. W. Blake, the able head-gardener, makes the following observations: "These are perhaps the most delicate and elegant of all the small flowering Irises. The grassy foliage and long stems, with flowers varying in colour from pure white to the darkest blue, make them most valuable for decorative purposes, and, above all, if grown in large masses they make grand subjects for the border. They will grow in almost any soil, but prefer a moist situation in full sun. Here at Clandon they are grown on the top side of the border of a large lake, while on the lower side, in still moister soil, are *I. Kampteri*. The *I. sibirica*

flower far surpass *I. sibirica alba maxima*. Several other varieties are grown at Clandon; among others, I may mention *I. sibirica* and *I. sibirica orientalis*, both splendid varieties of the blue or purple colour. Unquestionably the best of the blue varieties is the result of a cross between *I. sibirica* and *I. sibirica orientalis* (see illustration, page 364). So far it is unnamed. It has the habit of *I. sibirica*, while the flower is in size and shape that of *I. sibirica orientalis*, but of a much darker blue than that variety; the stems are tall and the foliage grassy, as in *I. sibirica*, which make it valuable for decorative purposes."

PRIMULAS AT MONREITH.

The other day I had an opportunity of seeing the Primulas in the garden of Sir Herbert E. Maxwell, Bart., at Monreith, Wigtownshire, and some interesting points were observed. *P. cockburniana*

IRIS SNOW QUEEN, THE BEST WHITE SIBERIAN VARIETY. (See page 303.)

proved to be biennial there, *P. pulverulenta* all died, while, rather curiously, *P. Poissonii*, which by most is found more tender than *P. pulverulenta*, has stood the winter and has been flowering splendidly. *P. littoniana* stood the winter, but did not flower this year, although looking strong and vigorous. *P. bulleyana* has again proved itself one of the best of the newer Primulas; *P. beesiana* has done well, and, associated with *P. bulleyana*, is much prettier than many would be prepared to admit did they see it with other flowers, the colour not appealing to everyone. *P. Forrestii*, which has been found a difficult subject in many places, looks as if it would succeed well, planted in the wall garden at Monreith. Unlike some of the other Primulas from China, it is said to do best in a dry position, and thus it is receiving at Monreith, with apparently satisfactory results,

although it has not flowered as yet. *P. Poissonii* is extremely fine, and has sent up handsome spikes in the border, even finer than I have seen it at Glasnevin, where it used to grow well in a moist place near the lake. At Monreith it is very handsome, and seeing it thus makes one regret the lack of success with it. *P. Veitchii* does very well in the border at Monreith. Of those mentioned now, *P. cockburniana*, *P. pulverulenta*, *P. bulleyana*, *P. beesiana*, *P. Veitchii* and *P. Poissonii* were in the ordinary border. *P. Forrestii* was in the wall garden in several places. *P. luteola* and *P. littoniana* were at the edge of a bed prepared for Lilacs, and, one may add, a fine lot of *P. capitata* was growing in a similar position. *P. japonica* is very well cultivated at Monreith, and a specially good form of *P. rosea* is thriving. Saxatile Primulas are also cultivated with success. S. ARNOLD.

THE GREENHOUSE.

SHOW AND DECORATIVE PELARGONIUMS.

THOUGH some sections of Pelargoniums are fully as popular as, if not more so than, they ever were, there are others but little grown nowadays. Among these last must be included the show Pelargonium, which was at one time very generally met with. True, show Pelargoniums are often referred to, but most of the different kinds included under that head at the present day do not at all conform to the old florists' ideal of that flower. The main characteristics of the show Pelargonium of old were a flower as nearly approaching a circular shape as possible, with the upper segments more or less notched, in many cases sufficient to almost cover the entire petals, while the lower ones were self-coloured or nearly so. Now, many of the so-called show Pelargoniums belong rightly to the decorative class; that is to say, that in which the shape of the flower and markings are quite subordinate to a sturdy habit and profusion of bloom. It is this class which appeals so strongly to the market-grower, with whom very few of the true show Pelargoniums were at all popular.

The last extensive raiser of show Pelargoniums was the late Mr. Foster of Clewer Manor, near Windsor, whose new varieties, which were annually distributed by Mr. Charles Turner of Slough, used thirty years or so ago to form one of the features of the season. One great object aimed at by Mr. Foster was the production of bright-coloured kinds, in which he succeeded in a remarkable manner. This was, however, accomplished by so much in and in breeding that the constitution of the plants became greatly weakened, the habit being thin and the flower clusters small. This led to other raisers working on different lines and the increased development of the decorative section, which has now practically taken the place of the show Pelargoniums. Another class that has almost disappeared from cultivation is the once-popular fancy Pelargoniums, whose flowers are borne in the greatest profusion. They are, however, too small for present-day ideas, when in flowers of all kinds size seems to be the most appreciated.

Valuable as all these Pelargoniums are for the embellishment of the greenhouse, they are now in many cases getting past their best, and must be taken in hand for their propagation or culture another year. When the plants are taken from the greenhouse, a good plan is to stand them out of doors for a week or ten days in a spot fully exposed to the sun, giving them at the same time

very little water. Then they should be cut back hard and laid on their sides for a time. This will encourage the formation of shoots, and as soon as these make their appearance the plants must be stood upright. When the new shoots are about half an inch in length is a good time to repot the plants. They should be shaken quite clear of the old soil, have any straggling roots shortened back, and be repotted into comparatively small pots. Then, whether placed in a frame or greenhouse, plenty of air should be given, the object being to encourage as short and sturdy a growth as possible, as upon this depends the production of leaves as close to the pot as possible. The earliest of the plants so treated may be shifted into their flowering pots in the autumn, and the others in early spring. A compost largely consisting of moderately heavy loam is very

A PROMISING HYBRID IRIS BY THE LAKESIDE, CLANDON PARK.

suitable for Pelargoniums, while it should also be pressed down firmly, as light soil and loose potting are conducive to soft, sappy growth. Cuttings may be selected when the plants are cut down. H. P.

GARDENING FOR BEGINNERS.

PROPAGATING BORDER CARNATIONS AND PINKS.

THESSE are two of our most popular border plants, which rarely fail to afford a lot of pleasure to the cultivator. The condition of the plants varies in different parts of the country and soils. It is a fact that in order to maintain a quite healthy stock of plants, frequent propagation is necessary. In some light soils the plants will live longer than in others of a similar nature, but in a different part of the country. Usually, I have found that those plants established in a well-worked medium to heavy loam last the longest in prime condition, producing "grass" of exceptional strength and large, well-colored blossoms. In all instances, however, propagation is needful every year, in order to reap the very best results these plants are capable of yielding.

Layering Carnations.—These plants are readily increased by the layering of available side growths—those formed near the outer part of the parent plant and convenient for placing flat on the border near them. The work may be extended over a considerable period, the month of July being very suitable. I have experimented with and successfully layered the plants as late as September in a light, sandy soil; but, of course, such late propagation is not advisable. Those I layered in September were not detached from the parent plants until the following spring. A nice open compost, some pegs or flat stones, and a sharp knife are the main requisites in layering. Procure some old loam in which the grass has died about two months previously, pass it through an inch-mesh sieve, use half loam, as sifted, and half-rotted leaf-soil. To one bushel of the combined parts add one peck of road grit or a 7-inch pottful of coarse silver sand. Mix thoroughly and it is ready for use.

In Fig. A, at No. 1, the older stems of the plants are shown. Nos. 2, 2 represent shoots suitable for layering, and No. 3 one layered in the prepared compost, No. 4. By making a hollow, as shown, and filling it with the compost, a more regular state of moisture is secured, and this conduces

THIS DIAGRAM WILL TEACH THE BEGINNER HOW TO LAYER CARNATIONS.

to early root formation. The basal leaves must be removed from the layer, as shown at No. 3; then make a slanting, lengthwise cut through a joint, keeping the lip open by inserting grit or sand, and make the layer secure by inserting a peg as shown, or laying on it a flat stone about three inches wide. Cover the stem well with the new compost, and water as required to maintain a regular state of moisture. If the peg is inserted as shown at No. 5, the lip will be kept open; if driven in as shown at No. 6, the lip will be closed, and then root action will be retarded. Pegs made of ordinary wood, or of Bracken Fern, as shown at No. 7, or wire pegs as shown at No. 8, may be used. No. 9 shows the stone recommended, and No. 10 the new roots when commencing to grow.

When Sufficiently Rooted take up the layers, cutting off the stem as shown in Fig. B at No. 1, and when replanting or potting just cover the roots, No. 2. No. 3 depicts a layer potted in a 3-inch pot; No. 4, a badly-rooted layer, the result of cutting the stem too far through at first and neglecting to give sufficient water.

Propagating Pinks.—Cuttings or pipings are taken and inserted in a cool border facing north, if one is available. As the cuttings are removed from the plants, place them in a vessel of water. When prepared for insertion in the soil, put them in another vessel of water; never allow them to become dry. The two lower leaves must be removed, as shown by the dark lines No. 5, and the stem, through the joint, may be slit open. No. 6 shows a cutting rooting nicely when so treated, but it is not absolutely necessary to slit open the stem. No. 7 depicts the right way to remove the leaf from the joint—by pulling—and No. 8 the wrong way—by cutting it off. If the stem is severed midway between the joints, as denoted at No. 9, roots would not form in many cases, but the stem would shrivel and decay, as shown at No. 10. Choice varieties, grown in low-lying districts, should be wintered in frames. G.G.

AND THIS ONE HOW TO MAKE AND ROOT PINK CUTTINGS.

TO DESTROY WEEDS ON LAWNS. WHATEVER method of destroying lawn weeds is employed, whether it be hand weeding or the application of some chemical substance, it is advisable to stretch two lines, about three feet apart, across the plot. That portion of turf enclosed by the lines should be treated, then one line moved to a similar distance beyond the other and that enclosed portion treated. The process is repeated until the whole of the lawn has been done. By adopting this plan there is no danger of any portion being missed, and if chemicals are applied a more even distribution is ensured.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Early Chrysanthemums.—These have made exceptionally good growth so far this season, notwithstanding the dry time during June, and as the lateral growths are now fairly long, they should be carefully tied. Aphis is still somewhat troublesome, so the tips should be regularly sprayed, or the buds, which will soon be showing, may become deformed.

Disbudding.—Good quality blooms may be obtained by judicious disbudding, and many of the early varieties may be so treated as soon as they appear. After this the plants must not be allowed to get dry at the roots, and a regular system of feeding should be adopted, just as though they were in pots, using a little artificial manure during wet weather.

Sweet Peas.—These ought to be making a brave show, even those sown late in the open ground. To preserve a good continuation of bloom, keep all the stale blooms picked off regularly, and never allow the plants to suffer a check through extreme drought at the roots. Feed with natural or artificial manure at least once a week, and, providing the plants are not suffering from streak, this should keep them growing vigorously.

Seed-Saving.—It often happens that certain plants of varieties stand out from their fellows, both as regards vigour in the plants and colour in the bloom. Such plants are worth marking, and if it is desired to save seed, these are the ones that are likely to give the best results.

Annuals such as Asters, Zinnias, Coreopsis and Salpiglossis may require staking to prevent them being damaged by wind or rain, and during hot, dry weather a good watering should be given occasionally. If liquid manure is at hand, this should be used in preference to clear water.

Plants Under Glass.

Chrysanthemums.—Many of the Japanese varieties have thrown premature buds this season, probably owing to the extreme heat during the latter part of May, and to get them to throw buds again as early as possible, after the end of this month the plants must be kept growing well. Those that are well rooted may be given the assistance of a little soot or cow-manure water, not too strong at first, but increasing it towards the end of the month.

Syringing.—All the plants should be well syringed every hot day, either once or twice, as time permits, and strict attention must be given to keeping the tips of the shoots free from aphis and thrips. These latter are apt to be troublesome at this season. Spraying seems the only remedy, and if thrips are noticed it is best to spray at once, as much damage is done even if left only a day or two.

Browallia speciosa, if potted on into flowering pots now, will give a good show of bloom during the autumn and winter months. A fairly light compost of leaf-mould, peat, loam and sand suits them best. If the plants are inclined to bloom, the points of the shoots should be pinched out. This will induce a more bushy habit of growth as well as retard the flowering period. A frame will suit them well for a time, giving a little shade during the very bright weather.

Bouvardias rooted in the spring and grown on should also be ready for transferring into 6-inch pots, and the same soil and treatment as advised above will suit them well, at least till they are well rooted, when they will stand more airy treatment. Older plants that may have been planted out in frames should be liberally supplied with water at the roots, and any of the long shoots that are growing too freely should be pinched back so as to preserve a nicely-balanced plant.

Violets have not had quite the amount of rain that they like, and should be well watered at least once a week, giving a sprinkling of soot between the plants before watering. Thus, I think, is a little help in keeping spider under—a pest which is very apt to be troublesome during dry weather. Should it attack the plants badly, endeavour to spray the under part of the foliage with a mixture of sulphur and soft soap.

The Kitchen Garden.

Perennial Spinach.—Where this is in demand, a good breadth should now be sown in rows from 18 inches to 2 feet apart, eventually thinning the plants to about a foot apart in the rows. Sown at this date, the plants do not get so large as those sown earlier; but the growth, I think, is maintained later in the season, and the resulting leaves are much more tender.

Brussels Sprouts.—Before these become too large the soil should be pulled up to them on either side to maintain the plants in an upright position, and if the soil is light, there is no harm in giving it a thorough good treading all round the plants when in a damp condition.

Celery.—Keep all Celery well supplied with water, both early and late planted. For very early digging one or two rows should be earthed up at once, but not before the plants have had a thorough good soaking of manure-water. Add the soil a little at a time, this being preferable to burying the hearts of plants at one operation.

Turnips.—Make a sowing or two of Turnips during the next few days for autumn use, following this up at the end of the month for later use. Red Globe and Golden Ball are good varieties for late use, though it is wise to sow one of the quick-growing white varieties to pull while the other varieties are maturing.

Fruits Under Glass.

Tomatoes.—Look well after the plants that are setting their fruits, as these will come in well for early autumn use. Give a top-dressing of soil and manure to the pots as they require it. For winter fruiting a sowing should be made of Winter Beauty, Sunrise, or some such medium-sized variety. Do not give too much heat during germination, afterwards treating the plants as hardly as possible, so as to have good, stocky plants with a set or two of fruit on ready for planting or potting during September or early October.

THOMAS STEVENSON.

(Head-gardener to E. Mockett, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Transplanting Biennials.—Wallflowers, Sweet Williams and other biennials should be transplanted before they get weakened through overcrowding. No manure will be required, but the ground, after being cleared of weeds, should be forked over. Generally speaking, 1 foot should be allowed between the rows and 9 inches between the plants in the rows.

Spanish and English Irises.—Where beds or clumps of these have been sown or planted with annuals to form a succession, the flower-stems of the Irises should be promptly cut over after the plants have finished flowering, so that the annuals may enjoy the maximum of light and air.

Geraniums.—The Crane's-bills are not so often seen in gardens as their merits deserve, and I would like briefly to call attention to them. The following are well worthy of a place in any collection of hardy border flowers: *G. armenum*, purplish crimson, 2 feet; *G. Fremontii*, pale purple, 1½ feet; *G. ibericum*, purplish blue, large flowers, 1½ feet; and *G. phœnum*, dark purple, 1½ feet.

Pansies and Violas.—Keep the spent flowers regularly picked off, except where it is intended to save seed. Where seed is required, the earliest available should be taken as soon as ripe; if delayed, the chances are that the seed-pods will burst and the seed will be lost. Cuttings of good Pansies should be taken whenever they are available. Insert the cuttings in boxes of sandy soil and stand them behind a wall or hedge.

Pentstemons.—Keep the hoe going among the plants, and give them an occasional sprinkling of soot or other fertiliser in showery weather.

Propagating Pinks.—It is quite time that this work was attended to. Some people adopt the rather rough-and-ready method of tearing off the side branches and planting them deeply in the soil; but propagation by cuttings, or pipings as some call them, is the correct method. Take the cuttings below the third joint, trim off the lower

pair of leaves, and cut the stem cleanly immediately below the joint; insert in boxes and place in a cold frame. Keep rather close and shade from bright sunshine until rooted; then gradually mure to air and light.

The Rose Garden.

Pinching.—Go over the plants and pinch out the points of all shoots showing undue grossness. The term "gross" is, of course, intended to be taken relatively. What would be a gross shoot on a Papa Gontier might be a very weak shoot on a Hugh Dickson. The thing to aim at is to maintain the balance of growth on the individual plant.

Climbers.—Attention should be given to tying in the young growths of climbers on arches, trellises, or pillars; those on walls should be nailed in. If aphides appear on the succulent points of the shoots, a puff of Tobacco powder will kill the insects.

Plants Under Glass.

Chrysanthemums. Attend to the tying of the shoots as growth advances. A watch will have to be kept for earwigs, and if they appear they can be trapped by placing pieces of crumpled paper among the shoots. The traps should be examined every morning.

Francoas.—Only in very mild localities can the Francoas be considered hardy, but they are very useful for conservatory decoration. As the flower-stems develop they should be staked and tied. For such slender stems I prefer wire stakes. Spring-sown seedlings should now be ready for potting up into 4-inch pots. Cold-frame treatment is what these young plants require. *F. ramosa* (white) and *F. sonchifolia* are both worthy of cultivation.

Dendrobiums.—Those which have finished their growth will be benefited by having a rather lower temperature and slightly drier conditions, both at the roots and in the atmosphere.

Fruits Under Glass.

Peaches.—In houses where the fruit has been gathered, the border should be examined, and if dry a moderate watering should be given. Continue to use the syringe or garden engine freely, and give abundance of air night and day.

Tomatoes.—Late crops in pots should be top-dressed as soon as roots appear freely on the surface. All laterals should be promptly pinched out, and tying should receive prompt attention.

The Hardy Fruit Garden.

Strawberries.—Plantations which are to remain another season should, as soon as the crop is picked, be cleared of weeds, and unless the runners are wanted for spring planting, they should be cut away. It will also tell on next season's crop if the plants receive a dose of liquid manure or a top-dressing of some approved fertiliser, to be applied in showery weather. The two correct periods for such an application is the present, in order to assist in the formation of strong crowns for next season's effort, or just after the fruit has set, to assist in swelling it.

The Kitchen Garden.

Jerusalem Artichokes.—On rich, heavy soils this crop is inclined to run too much to stem. Where such is the case, it is a good plan to pinch the plants when they have attained a height of from 5 feet to 6 feet. Under the above conditions they are also apt to be blown over by the autumn winds. If a few tall stakes are driven in and a line of twine is run round the plantation, it will help to obviate the evil.

Early Celery.—I am not a believer in earthing-up Celery at a very early stage, as it tends to retard growth; but the earliest planting should now be ready for a first earthing-up. It pays to tie up the plants with raffa previous to earthing-up, cutting it away after the earth has had a few days to settle about the plants. See that all side growths are removed before commencing to earth-up the crop.

Clearing Off Early Crops.—As soon as early crops of Peas, Cauliflowers, or Potatoes have been harvested, the haulm and stalks should be cleared off and removed to the refuse-heap, or dug down if the ground is to be trenched for another crop.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

IMPENDING RETIREMENT OF SIR HARRY J. VEITCH.

IT is with keen regret that we learn of the approaching retirement of Sir Harry J. Veitch, because it also means the disposal of the Veitchian Nurseries; but when we remember that he has already passed the allotted span of life, we can fully understand that the time has arrived for him to seek some respite from the strenuous duties connected with the directorship of such a large firm as Messrs. J. Veitch and Sons, Limited, of Chelsea. The lease of the Coombe Wood Nursery expires on Lady Day, 1915, so the present has been thought a suitable opportunity to decide the fate of this famous establishment, viz., to offer the nurseries and stock for sale; but some time will probably elapse before they are finally disposed of.

A few remarks on the history of the firm will, no doubt, be of considerable interest to the majority of our readers. Like so many other business houses, it had a small beginning, and so far as the records show, the original John Veitch came from Jedburgh in Scotland to Devonshire, and occupied a small portion of land at Killerton in 1808. Eventually his son, Mr. James Veitch, took command, and, to enable him to compete with other nurserymen, he purchased some land at Exeter in 1832, which was known as the Mount Radford Nursery. In April, 1853, the old-established business of Messrs. Knight and Perry of King's Road, Chelsea, was purchased by Mr. James Veitch, jun., at that time associated with his father at the Exeter Nursery, and was destined to become the head-quarters of a firm which will leave an indelible mark upon horticulture in all its aspects. His interest in the Exeter firm ceased in 1864. At this time the outside nursery covered about twenty acres. Fruit trees were grown on ground opposite the Chelsea Nursery, which were later transferred to Southfields, Fulham, and then to Langley and Feltham.

The Coombe Wood Nursery was begun in 1856, and this has been the home of everything choice and rare in the way of trees and shrubs. The first part of the Langley Nursery, where hardy fruits are cultivated on a large scale, also Roses, herbaceous plants and special crops for seed, was purchased in 1880. At Feltham fruit trees, Vines, bulbs and greenhouse plants are to be seen in great variety, while at Chelsea a big trade is done in seeds and various exotics.

With this slight digression we will pursue the family tree. In 1865 Mr. J. G. Veitch and Mr. Harry J. Veitch were admitted to partnership, and at the death of Mr. Veitch, sen., in 1869, the business was carried on by the two gentlemen just named. The partnership did not, however, last long, for Mr. J. G. Veitch died, at a comparatively early age, in August, 1870. Mr. Arthur Veitch then joined his brother Harry, but he having also died in 1880, for thirty years Mr. Harry J. Veitch was solely responsible, and it is probably due to his enterprise and energy that such progress was made during this period. He was succeeded in 1900 by his nephew, Mr. James H. Veitch, who died on November 20, 1907; but a year previous Mr. (now Sir) Harry J. Veitch had again assumed the managing directorship which he is about to finally relinquish.

Messrs. Veitch have from time to time despatched travellers to various parts of the globe in search of new plants. Among the first were the brothers

William and Thomas Lobb, the former collecting in California and South America, and the latter in India and Malaya, who introduced the first Nepenthes and the blue *Vanda cœrulea*. Richard Pearce travelled in Chile, Peru and Bolivia; John G. Veitch visited Japan, the South Sea Islands and Australia; David Burke went to Brazil, the East Indies, Burmah and Colombia; Henry Hutton to Java and the Malay Archipelago; Carl Kramer collected in Japan and Costa Rica; Gottlieb Zahn in Central America; Walter Davis in Brazil and Peru; George Downton in Central and South America and the islands of Juan Fernandez; J. Henry Chesterton in South America; A. R. Endres in Costa Rica; Gustave Wallis in Brazil, New Granada and various parts of Tropical South America; Peter C. M. Veitch, Australia, South Sea Islands and Borneo; Guillermo Kalbreyer, the West Coast of Africa and Colombia, South America; Christopher Mudd, South Africa; F. W. Burbidge, Borneo; Charles Maries, Japan and China; Charles Curtis, Madagascar, Borneo, Java, Sumatra and the Moluccas; J. H. Veitch travelled through India, Malaysia, Japan, Korea, the Australian and New Zealand colonies; E. H. Wilson, Central and Western China, and on the Tibetan frontier; while W. Purdon has only recently returned from a visit to China. It is impossible to enumerate any of the fine plants sent home by this host of collectors; but we might add that Messrs. Veitch have supplied material for upwards of four hundred plates in *Curtis' Botanical Magazine*—surely a record of which any firm might feel justly proud.

Many plants will still keep the name of Veitch alive, especially *Lilium anatum* (the Golden-rayed Lily of Japan) and *Ampelopsis Veitchii*, which is represented upon thousands of dwellings. Messrs. Veitch can also claim to be the pioneers of hybridisation, and it was their foreman, John Dominy, who raised the first hybrid Orchid. Soden continued this work, and John Heal devoted much time to the crossing of *Hippeastrums*, tuberous *Begonias*, *Rhododendrons*, &c., and *Nepenthes* and hardy fruits have received attention.

The foregoing is only a brief sketch of the history of the Chelsea firm, and in conclusion we earnestly hope that Sir Harry J. Veitch will be spared for some years to enjoy a well-earned rest. No man has done more for horticulture, and his interest in gardening charities is well known, for "Large is his bounty, and his soul sincere."

THE EDITOR'S TABLE.

Hybrid Primulas from Ireland.—Mr. J. A. Cooper, the Lissadell Nursery, Sligo, sends some beautiful hybrid Primulas of the pulverulenta and cockburniana types. Some of these are extremely pleasing, particularly No. 1, which has glowing scarlet flowers of large size. No. 2 has flowers of similar colour but not quite so good form. No. 12 has flowers of glowing orange scarlet, but the petals are too wide apart; it is, however, worth growing for its wonderful colour. No. 7 has blooms of a softer orange scarlet hue, and No. 6 is of deep crimson colour. The petals of this, like those of No. 12, are too far apart, a fault that will no doubt be remedied in time. Mr. Cooper writes: "We are sending you by parcel post to-day some specimen spikes of our hybrid Primulas, which may be of interest to you. We have labelled them under numbers."

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20 Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

INJURY TO THE LEAVES OF HARDY PLANTS (H. B. B.).—The leaves are injured by the larvæ of a small two-winged fly, probably the *Chrysanthemum* fly. Spraying when the attack is first seen with a nicotine wash is the best thing to do, or, if the leaves are sprayed with paraffin emulsion early in the season, the flies may be kept from laying their eggs.

CANTERBURY BELLS NOT DOING WELL (Dalbeattie).—Several creatures seem to be attacking the lower part of the Canterbury Bell stem and helping to its destruction. Are there many slugs or snails about? These often begin the work by nibbling the part near the root, and it is continued by other pests. The number and kind of different creatures present suggest the probability that there is insufficient lime in the soil. There is nothing in the Pink to account for the decay of the flowers. Their appearance suggests much wet as the cause of the trouble.

DOUBLE WHITE NARCISSUS (J. G.).—The bulbs sent are very small, while their crowded condition in any case would have precluded a good flowering. This variety is virtually a sub-aquatic, and, failing such conditions, should be given a cool place and the soil heavily dressed with cow-manure. If the whole of your bulbs are in the same condition as those you sent, you should lift and separate them at once, and in the replanting arrange the bulbs 5 inches or 6 inches deep. If treated as advised, they may remain undisturbed for years. In any case this variety should never be subjected to annual lifting and drying.

IRIS RETICULATA (K. E.).—This is a bulbous-rooted species flowering in the open in February and March, and growing, according to the strength of the bulbs, 6 inches to 9 inches high. The flower is coloured deep purplish violet, each of the lower petals (falls) having a golden blotch on it. The species is quite amenable to pot culture, should always be grown in very sandy, loamy soils, and in the open be planted about three inches deep. If the *Violas* are infested at the root with tiny white grubs and white mould, the cause of their sickly appearance is obvious. All you can do is to lift them, and having washed away all the soil, replant them in a new position. If the plants are very poor, you had better discard them and start with a fresh stock. The old position should have a free dressing of lime. The name of the plant is *Santolina incana*.

HERBACEOUS BORDER (X.).—You cannot do better than retain the poles for Rambler and other Roses throughout the entire length of the border, as no plants, rightly treated, are capable of a greater summer display than these. For the rest, you should now layer the Carnations and so obtain a larger stock. Lift the Spanish Irises now, so that the border may be made as free as possible for digging or trenching. Prior to this operation a good dressing of lime and a liberal one of manure will assist materially. With the trenching completed, you should obtain selections of *Pyræthrums*, herbaceous *Phloxes*, Irises (Flag and other sorts, also English and Spanish), together with such Lilies as *candidum*, *croceum* and *umbellatum*, and plant in free groups throughout. Then in spring you might plant the hybrid Pentstemons, which from July to September make a gay show. As you are interested in making the border a success, you should obtain from this office a copy of the "Hardy Flower Book," by E. H. Jenkins, which not only contains much valuable information, but includes plans showing how the plants should be arranged. Its price is 2s. 9d., post free.

FRUIT GARDEN.

DISEASE IN GOOSEBERRIES (Reader).—The Gooseberries appear to be attacked by the fungus *Botrytropharia ribis*, to which reference was made in our issue of July 5. There is no curative treatment, and all dead and dying branches should be removed as completely as possible and burned. We think it would conduce to the health of the bushes to spray them in winter with a solution of 2lb. of caustic soda in ten gallons of water.

PEACH TREE DISEASED (*F. T.*).—The Peach is suffering from the attack of the fungus *Exoascus deformans*, causing Peach-curl disease. This is usually more abundant where the plants have been exposed to winds and draughts. All the affected parts should be removed and burned, and next year the tree should be sprayed with ammoniacal copper carbonate soon after the buds burst.

INJURY TO RASPBERRIES (*H. T.*).—The white patches on the stems of the Raspberries sent are symptomatic of the disease due to *Hendersonia rubi*, but you do not send the lower part of the stem, where the disease is probably worse, so that we cannot say exactly whether this fungus or some other is at work. Spraying with Bordeaux mixture at the strength used for spraying Potatoes should be done, but not within three weeks of picking the fruit. The old canes should be cut out as soon as possible, and the young ones sprayed with the Bordeaux mixture, or with potassium sulphide, 1oz. to three gallons of water.

MISCELLANEOUS.

CRESTED LEAVES ON BRASSICAS (*W. L. Y.*).—The outgrowths on the Brassica are very curious, and frequently occur, no one knows why. They are associated with a derangement of the internal tissues of the plant, and occasionally appear to be associated with damage to the terminal bud.

NAMES OF PLANTS.—*G. S. D.*—1, *Mimulus glutinosus*; 2, *Rose Tuscany*.—*F. W.*, *King's Lynn*.—*Rose Alberic Barber*.—*F. M.*, *Selly Oak*.—Roses: 1, *Mme. Hoste*; 2, *Abel Carrière*; 4, *Nadia*; 8, *Captain Christy*; 12, *Anna Olivier*; 17, *Rev. A. Cheales*; 18, *Viscountess Folkestone*; 19, *Lohengrin*; 20, *Reliance*; 21, *Mme. C. Guinossan*; 23, *Baron de Bonstetten*. Others had fallen or were cut too small to be able to distinguish. —*L. B. C.*—Roses: 1, *Mrs. W. J. Grant*; 2, *M. Desir*; 3, *Prince C. de Rohan*; 4, *Ducher*; 5, *Jean Ducher*; 6, *F. Dubriou*; 7, *Rève d'Or*; 8, *Mme. G. Luize*. The flowers were poor and difficult to name with accuracy. —*A. P.*, *Sussex*.—1, *Colubra* species, send when in flower; 2, *Lythrum Salicaria* (Purple Loosestrife); 3, *Erigeron speciosus*; 4, *Coreopsis* species, send when in flower.

SOCIETIES.

HANLEY FLOWER SHOW.

This was held in Hanley Park on Wednesday, July 2, under happy auspices, in pleasant weather and under as bright skies as the atmosphere of these parts admit of, charged as it is for miles round with a haze or mist of smoke and dust arising out of the immense industry associated with the far-famed Staffordshire Potteries. If the sun is, unfortunately, somewhat obscured by the above conditions, a stranger has not long to remain in the Potteries before he finds out the fact that the sunshine which is born of the love of flowers and gardening is shining its brightest at Hanley on that day. The park in which this show, the seventeenth of the series, was held is one of the prettiest, best laid out and planted parks in the Midlands. A little more than twenty years ago it was a series of under-heaps! What a transformation wrought by the enterprise and public spirit of the governing authorities, with the help and through the agency of that art, the art of gardening, we all love so well! The committee and all concerned are to be congratulated on the extent and high quality of the exhibits throughout the show.

The groups of plants arranged for effect, of which there were five, filled the centre of one of the largest tents. A grand and effective sight they presented collectively, and, considered singly, nearly all were excellent. Messrs. Cypher and Sons were a good first; second, Mr. W. R. Manning, Dudley; third, Mr. W. A. Holmes, Chesterfield; fourth, Mr. W. Howson, Market Drayton; fifth, Mr. R. Simpson, Selly.

The classes for specimen plants, both flowering and foliage, were fairly well filled, and the competition was in many cases keen, Messrs. Cypher being the chief first-prize winners.

The class for twelve table plants brought out some of the daintiest and best-grown plants of this description we have seen for a long time. First, Mrs. Meakin, Dorlaston Hall; second, Mr. B. Howson; third, Mr. F. Winger, Wolstanton.

ROSES.

Of these there was a lovely show, a whole tent being chiefly devoted to them.

In the class for seventy-two, the first prize went to Messrs. A. Dickson and Sons, Newtownards; second, Messrs. Harkness and Co., Hitchin; third, The King's Acre Nurseries, Hereford; fourth, Mr. W. H. Frettingham, Beeston Nurseries, Notts.

In the class for forty-eight, Mr. Frettingham was first; second, Messrs. Harkness and Co.; third, Messrs. A. Dickson and Sons.

In the class for thirty-six the competition was keen, and many of the specimens were of superb quality. Messrs. Harkness were first; second, Mr. W. H. Frettingham; third, Messrs. A. Dickson and Sons; fourth, The King's Acre Nurseries.

In the class for twelve new Roses, distinct, introduced since and including 1911, Messrs. Perkins and Sons of Coventry were first; second, Messrs. A. Dickson and Sons; third, The King's Acre Nurseries; fourth, Messrs. Harkness and Co.

There were many other classes for Roses, including one for twenty-four Hybrid Teas. Messrs. Perkins and Sons

were first; second, Messrs. Harkness and Co.; third, Messrs. A. Dickson and Sons.

Twenty-four Teas or Noisettes: First, Mr. W. T. Mattock; second, Mr. W. H. Frettingham; third, The King's Acre Nurseries.

Twelve white Roses, one variety: First, Mr. W. H. Frettingham; second, Mr. W. T. Mattock; third, Burch Nurseries, Peterborough.

Twelve yellow Roses: First, The King's Acre Nurseries; second, Messrs. Perkins and Sons; third, Mr. W. T. Mattock.

Twelve pink Roses, one variety only: First, Messrs. A. Dickson and Sons; second, Messrs. Harkness and Co.; third, The King's Acre Nurseries.

Twelve red or crimson Roses, one variety only: First, Messrs. Perkins and Sons; second, Burch Nurseries; third, Messrs. Harkness and Co.

TABLE DECORATIONS.

Not the least beautiful and interesting was the tent devoted to these artistically-decorated tables. We do not know to whom the credit of introducing these decorated tables is due, but we do know the vast improvement which has taken place in the harmonious blending of colours, and in the light and artistic way in which the flowers have been arranged, since the introduction of these classes.

The first class in this section was for tables decorated with Roses alone, no other foliage than their own permitted. First prize went to Mr. W. T. Mattock; second, Mrs. A. J. Blair; third, Mr. S. Sims, Borrowash.

The second class in this section was for tables decorated with other flowers than Roses. Mrs. A. J. Blair was first; second, Messrs. Jervis and Sprowson; third, Miss Benyon.

Collections of hardy perennial flowers, no annuals, duplicates, or mixed bunches of flowers allowed. The magnificent collections of these which are always forthcoming at this show are a source of much interest to the public. Their growth may be enjoyed by all alike who may have a large or small garden, and on this account their merits appeal to the masses in particular. Messrs. Harkness and Co., Bedale, were first; second, Mr. F. Bonskell, Market Bosworth; third, Messrs. Gibson and Co., Bedale.

SWEET PEAS.

For a collection of twelve varieties, twenty-one stems of each, the first prize went to Mr. F. R. Minshall, Market Drayton. No other award was made.

FRUIT.

Considering the earliness of the season for many fruits, such as Muscat Grapes, Apples, Pears, and Plums, the exhibition of these was good.

In the class for a dessert table decorated with flowers and foliage, the exhibit which took the first prize consisted of really superb fruits, the exhibitor being Mr. Doe of Olberton. His Black Hamburg, Madresfield Court and Muscat Grapes were splendid specimens of the grape-grower's skill, judged from all points. Second, Lady Beaumont; third, Mr. W. T. Mattock.

Collection of twelve dishes of fruit, not less than eight kinds and not more than two varieties of a kind, to include black and white Grapes, two bunches of each variety: First, Lady Beaumont, Carlton Towers, with an excellent collection; second, Mr. S. Sims, Borrowash.

In the class for six distinct dishes of fruit, that veteran fruit-grower and exhibitor, Mr. Bannerman of Blithfield, was an excellent first; second, Mr. J. Doe.

In the class for four bunches of Grapes, two black and two white, Mr. Doe was first, Lady Beaumont second and Mr. Bannerman third.

The minor classes for fruit were generally well contested and the quality good.

HONORARY TRADE EXHIBITS.

These are always a notable feature of the Hanley Show, and on no occasion have they proved more attractive and received greater appreciation than this year. Messrs. M. Jenkinson and Son of Newcastle were awarded a silver challenge cup and a large gold medal for a magnificent collection of Roses; Mr. W. Lowe, Beeston, Notts, large gold medal; Mr. R. Bolton, Warton, Carnforth, large gold medal for a fine collection of Sweet Peas; and Messrs. Jervis and Sprowson, gold medal for an artistic example of floral room decoration.

Silver medals were awarded to the following firms: Messrs. Jarman and Co., Chard; Messrs. Dicksons, Limited, Chester; and Messrs. S. R. Compston and Sons, Macclesfield.

THE CHILDREN'S SECTION.

In many respects the large tent devoted exclusively to children's exhibits is the most interesting part of this excellent show. Started in an unpretentious way a few years ago, it has now attained to great proportions, upwards of two thousand entries being received in the various sections in which the children are interested, and in most of which they receive instruction at school. Examples of children's work in the following subjects were on view. The same were judged by ladies and gentlemen of scholastic and artistic standing in the town, and suitable awards made. Plants and seeds are distributed in the spring among the children unable to provide themselves with the same; others provide their own. All start growing them at the same time, and under similar conditions as regards size of pots and so on. All the exhibits were creditable to the children, and some would have stood a good chance for a prize even among the exhibits of experts. Another strong feature is the water-colour drawings of plants from Nature. The children range in ages, we believe, from seven to twelve, and their work in this section was truly most praiseworthy, the plants in most cases being so true in colour and outline to the

original. Dried specimens of wild and cultivated flowers were another most interesting aspect of this children's show. That they had been dried and pressed with the utmost care was clear by the colour of the foliage being so well preserved. Each example was correctly labelled, giving both the common and the botanical name. There were also many exhibits of plants and flowers in pastel drawing, as well as examples of trees in pencil drawing. Think of the innocent pleasures these studies afford to the plastic and easily-impressed mind of the child! Think, also, of the pleasure stored up for future enjoyment, and of the influence for good! Such studies cannot help but encourage and foster the love of flowers among those who come after us. All honour, we say, to the promoters of the Hanley Show for the lead they have taken in so important and far-reaching a movement for good among our children.

SOUTHAMPTON ROSE SHOW.

By permission of Ellen Lady Swaythling, the annual Rose Show was held in the beautiful grounds attached to South Stoneham House on June 25, and if not so large as in some years past, was of an interesting character. The Roses were of capital quality, fresh, well coloured and consisted of an extraordinary number of newer varieties, so much so that we missed an unusual number of old favourites. The Hybrid Perpetual section was almost unrepresented, so popular have the many Hybrid Tea varieties become. The arrangements were, as they always are here, excellent, under the experienced guidance of Mr. C. S. Fudge, secretary, and the chairman of committee, Mr. H. E. Molyneux. In all, twenty-seven classes were provided for cut blooms in the schedule, ten being open to all. The principal one was for forty-eight distinct varieties. There were four competitors, making an effective display. Mr. G. Prince, Longworth, Faringdon, was easily first with medium-sized high quality specimens. The best were Jonkheer J. L. Mock, Lyon Rose, Mme. Jules Graveureux, J. B. Clark, Bessie Brown, Edward Mawley, Ethel Malcolm, Lady Ashtown, Mildred Grant, Oberhofgartner Terks (extra fine), Mrs. M. Sinton, Lady Ursula, Mrs. G. Shawyer, Marquise de Sincy, Medea (large), Mrs. A. Coxhead, Avoca (richly coloured), Mrs. Myles Kennedy, Mrs. Sam Ross, Mme. Melanie Souper and Mabel Drew. Messrs. D. Prior and Sons, Colchester, were second with larger specimens, which, however, were not so clear or well coloured. Lady Barham was so fine that it was selected as the premier bloom in the open classes. Mrs. J. H. Welch, Lady Ashtown, Maréchal Niel, Victor Hugo and Mrs. Arthur Coxhead were also noteworthy blooms. Mr. J. Mattock, Headington, Oxford, was placed third.

Five competed for twelve Teas or Noisettes. Mr. Prince followed up his previous success by annexing the premier award with remarkable blooms of Mme. J. Graveureux, Mrs. F. Hobbs, Comtesse de Nadaillae, Mrs. Myles Kennedy, Mme. Cusin, Souvenir de S. A. Prince, Mrs. Herbert Stevens (a wonderful blossom, so pure in colour), Mrs. E. Mawley, White Maman Cochet and Molly Sherman Crawford, Alexander Hill Gray, Esq., Beauhien, Newbridge, Bath, was second with a good set. W. R. Smith, Mrs. F. Hobbs, Nita Weldon, Maman Cochet and its white counterpart were deserving of note. Mr. H. Drew, Longworth, Berks, was third.

Mrs. Foley Hobbs won for Mr. A. Gray the leading award for six any yellow or white, Messrs. Prior and Sons depending on Bessie Brown for second place.

For a representative group in 50 square feet, six entered but only two competed, which, when withdrawn at the last moment, is a serious loss to the executive. Mr. J. Mattock was easily first with a capital display of free-flowering varieties, effectively arranged in tall masses of such varieties as Lady Curzon, Irish Elegance, Crimson Damask, Marquise de Sincy, Lady Hillingdon, Juliet, Mrs. W. J. Grant, Murburst, Goldfinch and A. R. Goodwin. Messrs. W. and R. Rogers and Sons, Bed Lodge Nurseries, Southampton, were second.

Baskets of cut Roses, in three distinct sorts, made a good display. Mr. J. Mattock was easily first with Ethel Malcolm, Lyon Rose (grandly coloured) and General MacArthur. Messrs. Prior and Sons were second with good blooms not so well displayed, Mr. Prince following.

AMATEURS.

For eighteen, distinct, four entered. Mr. W. Jarratt Thorpe, Gransmoor, Huelcleote, Gloucester, won the premier place with desirable specimens—Mrs. F. Hobbs, Ulrich Brunner, George Dickson (a good example of this new Rose), Jonkheer J. L. Mock, Bessie Brown, Francois Michelon and Princesse M. Metchersky. Mr. A. Hill Gray was second with smaller specimens, and Dr. Seaton, Woodside Cottage, Lymington, third.

In the class for six Roses, three of each variety, five took part. Mr. A. Hill Gray won with a good set, in which Lyon Ulster and W. R. Smith were the most prominent, Mr. W. J. Thorpe being a close second.

Mr. A. Hill Gray won for twelve Teas or Noisettes with a grand bloom of W. R. Smith in particular. Dr. Seaton was second.

Open to growers of less than five hundred plants, a class for twelve blooms, distinct, was made. Dr. J. T. Gillett, Andover, was first, The College, Winchester, won the piece of plate for twelve, for growers of less than three hundred plants, with desirable blooms.

In the classes confined to the County of Hants, Mr. H. E. Molyneux, Brantwood, Southampton, won the Allan Ginn Cup for twelve distinct blooms, among six entrants, with an interesting set composed mainly of new varieties—Mrs. T. H. Vanderbilt, Colleen, Portia, Laurent Carle, Mrs. Mair Mackean and Mrs. Amy Hammond. Mr. R. C. W. Dixon, Glenville, Hulse Road, Southampton, was a good second.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return any accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographs in name of the copyright will be treated with

The Editor will not be responsible for the return of articles or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be considered as acceptance.

Office: 29, Abchurch Lane, London, E.C. 4.

NOTES OF THE WEEK.

Destruction of Queen Wasps.—One of the most certain methods of keeping down a plague of wasps is that of capturing the queens. An interesting exhibit in connection with the recent El-tree and Boreham Wood Horticultural Society was the class for queen wasps, the first prize being awarded for 175 specimens.

Rose Show at Gloucester.—In responding to the toast, "The National Rose Society," at Gloucester last week, Mr. Mawley said this was the largest provincial show ever held by the National Society, the next largest having been at Saltaire, and the next largest at Luton. Not only that, but he thought the general quality of the blooms was far in excess of anything they before. A report of this wonderful display of had had Roses appears on another page of this issue.

Robert Sydenham.—It will come as a great shock to many of our readers to learn of the death of Mr. Robert Sydenham, which occurred suddenly at his office, Tenby Street, Birmingham, on Saturday morning last. So recently as Thursday evening of last week he was present at the dinner of the National Sweet Pea Society in London, and appeared to be in his usual good health. His death removes from the gardening world a genial and generous personality that will be greatly missed by a large circle of friends. A portrait of the deceased gentleman, with a brief review of his career, appears on page 379.

A Beautiful July-flowering Broom.—In *Cytisus nigricans* we possess a yellow-flowered Broom of considerable value in gardens. The fact that the plants continue in flower practically throughout the month of July should not be lightly overlooked, for hardy shrubs which flower profusely at this season are not over-abundant. To obtain bushes of *Cytisus nigricans* in their fullest beauty it is necessary to cut the previous season's growth fairly hard back in February or March each year. By this means vigorous young shoots are induced to develop, almost every one of which later terminates in a long, slender raceme of yellow blossoms.

Wart Disease of Potatoes in Lancashire. The Board of Agriculture and Fisheries desire to inform Potato-growers that cases of wart disease of Potatoes (*Synchytrium endobioticum*, Perennial) have occurred in Lancashire, and to remind them that by Article 3 of the Wart Disease of Potatoes Order of 1912 they are required to report the presence of this disease on their premises to the police or other officers appointed by local authorities for the purpose, and that failure to report is punishable by a fine. Notifications may be sent to the Board, who will forward them to the proper quarter. A leaflet describing the disease and giving directions

for dealing with it can be obtained from the Secretary, Board of Agriculture and Fisheries, 1, Whitehall Place, London, S.W., gratis and post free. Letters so addressed need not be stamped.

Propagating Rock Plants by Cuttings. The majority of rock plants that have now finished flowering can be readily raised from cuttings. Select the young growths and place them in sandy soil under a hand-light, and keep a moist atmosphere by occasional overhead syringing during bright weather. By these means many plants that are not easily raised from seed can be readily increased. When rooted they should be potted off, and will make nice plants for the rock garden the following spring.

County Classes for Sweet Peas.—One of the most interesting features of the National Sweet Pea Society's Show, held in London last week, and a report of which appears on page v, were the classes arranged for groups of counties, these embracing the whole of the United Kingdom. We are pleased to announce that the piece of plate presented by us as first prize in the Southern Counties Class was won by Mrs. Kensington, Havering, Buxted, Uckfield (gardener, Mr. F. C. Bealey). As there were eight entries, this was exceedingly creditable, and we congratulate Mrs. Kensington and her gardener on their success.

Are Ten-Week Stocks Dying Out?—During the past two seasons we have been called upon at shows to judge Ten-week Stocks, the schedules rightly stipulating that the plants should be shown as grown. In nearly every instance the plants staged have been those of the intermediate section, many of which are of a perennial or semi-perennial character. These are naturally much larger and more branching than the old Ten-week Stock, and undoubtedly better plants for the garden. In judging we have hesitated to disqualify these exhibits, but it would be well if framers of schedules would ask for Stocks raised from seed sown during the current year, and thus make it quite legitimate for exhibitors to stage those of the intermediate section.

A Beautiful Rambler Rose. A well-grown plant of the Rambler Rose *Excelsa* growing over the top of a broad gateway moves us to draw the attention of readers to this welcome addition. In our opinion it will before long oust *Crimson Rambler* from most gardens, the soft yet bright cherry red colour of the flowers being far more pleasing than those of the old variety. When we saw pot-grown plants of *Excelsa* shown two years ago, we were not favourably impressed with it, as the blooms had an unpleasant blue tint running through them. Outdoors, however, this is absent, and at a distance the flowers are practically the same shade as some newly-opened ones of *Crisis* or *Teplitz* that are growing near it. *Excelsa* is a *whitமான* Rose, has a vigorous habit similar to that of *Dorothy Perkins*, and flowers freely.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Willow-Leaved Veronica.—Although the varieties of Veronica are numerous, the Willow-leaved species, *V. salicifolia*, is quite one of the best. A plant here put out five years ago at the foot of a south wall in quite a narrow border has succeeded well; it is now 6 feet across and 4 feet high, and is completely smothered with its pure white, drooping racemes 8 inches long—a glorious sight when in full flower. It is a pity the flowers do not last longer. They are short-lived, a fault with all the Veronica family. Nicholson describes this variety as bluish purple or white. In my case the flowers are pure white. Perhaps this is a superior form.

Phlomis fruticosa.—The Jerusalem Sage, as this hardy shrub is often called, although a common plant, introduced as far back as 1596 from the Mediterranean region, is not grown nearly as much as its merits deserve. In low-lying, damp districts the plants are more easily injured by frost; hence perhaps the reason for their scarcity. Here on a hill, in well-drained yet heavy soil, the specimen I have flourishes amazingly, producing a full crop of its yellow or dusky yellow whorls of blossom. My plant is about seven feet in diameter and 5 feet high, the result of ten years' growth. Even when not in flower the plant is desirable, being evergreen, with an under surface of white wool. — E. MOLYNEUX, *Swanmore Park, Bishop's Waltham, Hants.*

The Lowberry Fruiting Well. It may be interesting to some of your readers to know that this comparatively new berry is fruiting well in the open in the garden here. When shown by Messrs. Stuart Low and Co. about three years ago, doubts as to its hardiness and fruiting properties were freely expressed. It produces long, jet black fruits in clusters similar to those of the Loganberry, but the flavour more closely resembles that of the Blackberry. It makes long, stout rods, and is excellent for covering trellis-work. I should be glad to hear the experiences of other readers with this useful berry. — J. B. S., *Redhill, Surrey.* [We have this plant fruiting freely in Essex just now, and it appears to be perfectly hardy. The fruits are sweeter and more useful than those of the Loganberry.—ED.]

Three Good Astilbes.—For moist situations in the border, and especially by the water-side, the Astilbes are a family whose value cannot be over-estimated. There are now several fine varieties of recent introduction, of which Cream Pearl, Pink Pearl and Venus are among the best. These were raised by M. Arends, and are known as Astilbe Arendsii. All three are sturdy, erect growers. Cream Pearl has, as its name implies,

creamy flowers, freely produced. Pink Pearl is a pleasing shade of soft pink. Venus is a grand plant with large spikes of deep pink flowers. To lovers of hardy plants on the look-out for good things, these should be especially welcome.— E. G. DAVISON, *Westwick Gardens, Norwich.*

Primula Rusbyi.—It is but seldom that we meet with *Primula Rusbyi* in flower, and it is with pleasure that one sees a nice little plant photographed in the garden of Dr. John MacWatt at Morelands, Duns. It is one of the *Primulas* which, like *P. suffruticosa*, baffle a good many and prove difficult in many ways. Its New Mexican origin may account for a good deal of the trouble experienced with it, although on good authority

with Larina. The longish, rather spoon-shaped leaves are toothed. It was introduced in 1881.— A. P. PINIST

Good Herbaceous Borders in Scotland.—Mr. John Wilkinson, agent for Captain Hope of St. Mary's Isle, Kirkcudbright, has a delightful garden at The Grange, Kirkcudbright. Many things are well done there, but perhaps the most charming feature is the way in which the hardy border flowers are cultivated and arranged. This part of the garden is cared for by Mr. Wilkinson himself, and the plants, their cultivation and their arrangement all contribute to the successful results obtained. The borders are on either side of grass paths, which give an air of peacefulness and harmony

with the flowers often wanting in gardens where gravel is employed for the walks. The plants are in bold groups of one variety, and the effect through the varying seasons is very beautiful. The other day, although the great Oriental Poppies, which are so fine at The Grange, and other earlier flowers were over, the effect of the borders was charming, especially in the long borders on either side of the main pathway. Great Delphiniums, clumps of *Alstroemerias*, *Veronicas*, white and red *Valerians*, *Polemoniums*, *Violas* and many other border flowers, supplemented by such annuals as *Alonsoas*, *Dimorphotheca aurantiaca* and others, made a wonderfully beautiful effect, enhanced greatly by the surroundings of trees and shrubs and the absence of walls.—S. ARNOTT.

Roses that Vary in Colour.

The extreme variations in colour of some Roses have more than once given rise to the impression that the vendor has sent a wrongly-named plant. In the newer Hybrid Tea Rose *Sunburst* we not unnaturally find some difference of opinion as to its sterling qualities. A well-coloured flower is really a revelation in golden orange and cadmium yellows; but so often we get a quantity of flowers almost devoid of this delightful colour, and then it is by no means so great an acquisition, and has often been decried from that cause. We have another notorious example in Mrs. Aaron Ward. About an equal number of the blossoms equal a clear Indian yellow and the rest almost a creamy white, while some range from creamy white, flushed with salmon rose, up to various shades of the more striking Indian yellow. William Allen Richardson has much the same undesirable peculiarity. But it does not seem possible to altogether account for these variations. Position, soil, also whether under glass or in the open and whether sunny or dull weather predominates, are frequently put forward as causes. Other varieties that change greatly are *Prince de Bulgarie*, *Marie van Houtte*, *Edu Meyer*, *Duke of York*, *Hugo Roller*, *Souvenir de Stella Gray*, *Rambow*, *Theresa* and *Mme. Lambert*. My object in this note is to help to clear away some thoughts of dishonest trading that have more than once been expressed to me by growers.—A. P.

THE NEW ROSE G. AMEDEE HAMMOND, EXHIBITED BY MESSRS. ALEX. DICKSON AND SONS AT THE GLOUCESTER SHOW LAST WEEK. (See page vi.)

we are told that it is a hardy rock garden species. It has not turned out hardy everywhere, and is really most satisfactory in a pot, in a frame, or, better still, in an alpine-house. A soil of loam, peat and sand in equal parts, with some stones among it, or with leaf-soil in substitution for the peat, I found answer best; but it is both a troublesome and shy-flowering species in the open. The flowers, which are sometimes called "a brown crimson," are a little depreciated by this description, the colour being a nice crimson-purple, with a yellow eye surrounded by a deep crimson shading. The beauty of the flower is increased by the pretty way with which the calyx is striped

New Roses Grown Under Glass. Messrs. Alex. Dickson and Sons of Newtownards inform us that all the new Roses shown by them at the National Rose Society's London Show on July 1, and described in our issue for July 12, were grown in the open, and not under glass as stated in our report. The mistake was due to the fact that there were two classes for seedling Roses—one for those grown in the open and the other for those grown under glass—and it not being made clear in which class the various Roses were included.

Campanula G. F. Wilson.—I have seen *Campanula G. F. Wilson* in many places, but never in such plenty as in the beautiful gardens of Captain Hope, R.N., at St. Mary's Isle, Kirkcubright, where it is cultivated most extensively in the borders and rockery. There are many large clumps of great beauty, these covering themselves so freely with the dark blue flowers that hardly a leaf is to be seen. The clumps in the front of the borders, in particular, are of large size, and all are the produce of one plant which was in the gardens when Mr. James Jeffrey, the gardener, took charge a good many years ago. The variety is the green-leaved one.—S. ARNOTT.

Scent in Flowers.—In reply to Mrs. King's query on page 334, issue July 5, concerning my allusion to the American craze for size and colour, I had in my mind when writing some very large and showy Peas (miscalled "Sweet") that came from an American source, which I saw for the first time in a friend's garden some years ago; but when I tip-toed up to smell them, I discovered, to my dreadful disappointment, that they had no scent, and though so gay, would never make a *nose gay*! I had also in my mind the large and showy American Apples and other fruit (so often seen in fruiterers' shops) which we find so sadly lacking in flavour. As for the American love of everything large, that charge did not originate with me.—ANNIE AMATEUR.

Pruning Rose La France.—No doubt some cultivators of this lovely Rose will think it is quite unseasonable to talk about pruning Roses, but I think it is quite seasonable, and a subject on which readers may give their experience. I find the best results follow summer pruning, or, rather, thinning out of the old wood at this time, and thus allow the younger and stronger shoots to mature before the winter comes. Ordinary cutting back to two, three, or five buds in March has not, as far as my experience goes, resulted in the best crop of flowers being grown. Really unripe wood may be cut back, but if the summer pruning is well done, very little will be necessary in spring. General thinning out of shoots now and a little shortening back of unripe tips of shoots in March have given the best results as regards flowering, and in a few years the plants have attained to a large size, bearing dozens of blooms. Perhaps some other cultivators will give their views.—G. G.

FORTHCOMING EVENTS.

July 29.—Royal Horticultural Society's Meeting and Gladiolus Show. Masters Memorial Lecture at 3 p.m. by Professor R. H. Biffen, M.A., on "Some Factors in the Prevention of Disease in Plants."

July 30.—Midland Carnation and Picotee Show at Birmingham (two days). Flower Shows at Chesterfield, Whitechurch and Bishop's Stortford.

July 31.—County Clare Summer Show. Flower Shows at St. Ives (Hunts) and Northallerton.

August 2.—Société Française d'Horticulture de Londres Meeting.

CULTURAL NOTES ON NEW OR RARE PLANTS.

Saxifraga bursiculata.—This is probably one of the most valuable of hybrid Saxifrages raised during recent years. It was raised from a cross between *S. burseriana* major (the true plant) and *S. apiculata*, and, while embodying not a little of the vigour and freedom of growth of the latter plant and its clustering trusses of flowers, embraces all the purity of colour and earliness to bloom of that first named. It is, from every point of view, a hybrid alpine to which the term "first class" might well be applied. It is of free growth, though doubtless a year or two will elapse before it becomes either plentiful or cheap. Meantime, it will satisfy those who consider the best of everything quite good enough. By reason of its vigour it grows freely in gritty, well-drained loam. Its earliness to flower—February-March—fits it for the alpine-house.

Fritillaria imperialis chitralensis is a plant so distinct and dwarf-growing by comparison with others of the "Imperial" race that at sight it might be regarded as outside its scope. Botanists, however, have declared to the contrary, and as the plant is an early-flowering one of the bulbous order, and one that, to ensure complete success, should be planted in late summer or early autumn, note should be made of it now. It is a foot or so high, having golden yellow flowers of bell-like outline. It is a refined and pretty plant, well suited to very sandy soils and a warm situation. Flowers March-April.

Oxalis adenophylla.—Whether this pretty Chilean species will prove a little less hardy than the varieties of *O. enneaphylla*, time alone will prove. Meanwhile, it is worthy of every care and the studious avoidance of risks. In the warmest positions of the rock garden it may be safe enough, and in the drier parts of the moraine may be worth experimenting with by those who have enough for such purposes and the courage to use them. Culturally, it appears to require nothing different to the better-known plant. The glaucous, much-divided leaves form a tuft, which constitutes a pretty setting to the pinky red flowers, which appear in April and May. In the alpine-house it is one of the choicest of early flowers.

Anemone sylvestris grandiflora.—On the principle that a good variety of any plant takes up no more room than an inferior one, and sometimes not quite so much, it is suggested that all interested in the Snowdrop Windflower should secure the variety above named. Some of those sent out as the typical kind are of too weedy a nature, both in habit and flower. Occasionally one may get the *grandiflora* form when ordering the other, and where this is so, it should be taken care of. Of quite easy culture in light or medium well-drained loam, its nodding Snowdrop-like buds have a very pretty appearance before the fully-opened flowers appear in May. For good distinctive varieties of such things, the best method of increase is by division.

Dianthus Pulhamii.—For the larger rock garden in June, this fine single-flowered, deeply-fringed Pink is particularly good. The plant grows 1 foot high and has bluish pink, crimson-based flowers of 1½ inches across, which, backed by a neat tuft of glaucous leaves, make a great show. Like all its tribe, it is of quite easy culture in gritty loam and old mortar. Pippings in July are the best method of increase, though seedlings might also be raised.

E. H. J.

THE GREENHOUSE.

BEAUTIFUL PLANTS FOR HOUSE DECORATION.

(SCHIZANTHUSES.)

AS decorative subjects during the spring and early summer months *Schizanthuses* are difficult to beat, as with ordinary cultivation in a cool greenhouse a succession of bloom can be had from March till the middle or end of June by sowing at different dates in the autumn and early spring. Though autumn-sown plants give the best results, both for size and floriferousness, February sowings are not to be despised, as really excellent plants are to be obtained in 4½-inch and 6-inch pots, the chief essential in each instance being a very steady growth in a house with plenty of light and air at all times. This is especially desirable when the plants are coming into flower, for if given shade and a trifle too much heat at this time, the flower-stems become attenuated and are apt to fall about in a very ungainly manner. As decorative plants for the dwelling-house, winter garden, or conservatory, there is no annual that will give a better return for the trouble taken with them, and as the varieties are so distinct in habit and colour, they seem to adapt themselves to any and every decorative scheme.

In my early days of gardening I can only remember the old *pinnatus* type being grown to any extent, and as far as my memory serves me, they were of much more straggling habit than the strains we get now; but having a very large conservatory to furnish, they impressed me very much, as the plants were grown five or six in a 12-inch pot and attained a height of about six feet. Even now, where large plants are wanted for the conservatory, a good strain of *pinnatus* and *pinnatus rosea* are about the best. It is true that we have strains of large-flowered varieties which vary greatly in colour from white through the various shades of mauve and pink to a dull red or magenta; but none of them produce the same beautiful gauzy effect as do the first-mentioned varieties, and some of the strains, to be seen from a decorative point of view, are not worth perpetuating.

The plant shown on page 372 is of the type mentioned. It was pinched about twice in the early spring and potted finally into a 12-inch pot, and when photographed it was probably 6 feet 6 inches in height, 2 feet 6 inches to 3 feet in diameter, and was one of several such plants which were used for furnishing the winter garden here. The larger-flowering hybrids, as they are called, I find do not make such large plants, 8½-inch pots being large enough for them; but these also are very useful for house and conservatory decoration, especially if the colours are chosen with care.

The *wisetonensis* type is quite distinct, both in the habit of plant and colour of bloom, and where smaller plants are required of compact form these are excellent, the yellow markings in many of the plants making them especially desirable toils to the mauves of some of the other types. A bright rose pink form of this type sometimes met with should be developed, and if it could be had true, I am sure it would command a ready sale. Amateurs and others whose greenhouse accommodation is limited would be well advised to grow only the *wisetonensis* varieties, as a good many plants can be grown in a small space.

The *retusus* type is also quite distinct from the others. The orange or yellow blotch in the centre

of the bloom makes it quite striking in colour, the main portion of the bloom varying in different varieties from pure white to almost a carmine, and for grouping purposes, either at exhibitions or in the conservatory, they are eminently suitable. Also as cut flowers these varieties stand well, and are much admired for table decoration. Unfortunately, these latter are not quite as easy of cultivation as are most of the others; but with fairly careful watering during the winter they should present no serious difficulties to the ordinary gardener.

Cultural Hints.—To be really successful with all or any of the varieties, a sowing should be made in September or October, preferably in small pots, four or five seeds in a pot, thinning the seedlings to one in a pot when large enough to handle. Keep them during the winter on a shelf in a quite cool house, potting on as the pots become full of roots until the desired size of pot is reached. Where a really light and airy span-roofed house can be requisitioned for growing them, pinching is not necessary, unless it is to retard the flowering period, and they will make quite shapely plants without it; but when grown with other plants it is sometimes advisable to pinch them once or twice to make them a little more bushy.

In a close, stuffy atmosphere, or if too much heat is given, the growth very quickly becomes attenuated and the keeping qualities of the blooms are much impaired. When the flowering pots are full of roots, they will take liquid manure quite freely; but too much artificial manure is not advisable. At no time during their growth will they stand drought at the roots, so, in addition to plenty of light and air, careful watering is the one other detail absolutely essential to success. THOMAS STEVENSON.

Addlestone, Surrey.

CASSIA CORYMBOSA.

This lovely shrub is in full flower during the month of July when treated as a cool greenhouse subject, a little earlier when some heat is given, and during the latter half of July and the first part of August when grown in a sheltered corner outside. Half-ripened shoots root readily if inserted in a sandy compost in heat, and harder wood will form roots if placed in a cool frame. Plants may also be raised from seeds sown in April. They make splendid specimens when grown in 10-inch pots, and are most useful to amateurs who possess unheated or only slightly-heated glass structures. In the Southern Counties the plants will succeed against a south wall, and require very little protection in the winter-time. Fibrous loam two parts, peat one part, with leaf-soil and sand one part, form a suitable compost both for plants in pots and borders. The colour of the flowers is a rich buttercup yellow, and they are borne in clusters. B.

THE FRUIT GARDEN.

THE EARLY PLANTING OF STRAW BERRIES.

THE daily gathering and consuming of luscious dishes of luscious Strawberries during the past few weeks lead us to wonder how it is that this fruit receives such scant attention from the average amateur. The professional gardener has of necessity to grow it well, and keep up a succession over as long a period as possible; but in the majority of comparatively

and often better than the earliest; hence it would appear to be a good investment for anyone who would take up their cultivation on a comprehensive scale.

This brings us to the heading of this article, viz., the value of early planting. The bed from which we have been enjoying fruit for at least four weeks, and which promises to give us a good supply for nearly another three, was planted at the end of July last year, and therein lies its success. Had planting been postponed until well into September, as is too often the case, fruit would have been, to use an aphorism, conspicuous by its absence. The plot had been previously heavily manured, deeply trenched, and cropped with Potatoes Midlothian Early, which were lifted in the green state for immediate use. Then the ground was forked over, all lumps broken up well, and subsequently allowed to settle for a week or so before the Strawberries were planted.

These were put in rows about eighteen inches apart and the plants a foot asunder in the row, the idea being to remove every other plant and row after the fruit is all gathered this year. The plants were well watered until thoroughly established, so that they had every opportunity of making good crowns last autumn. It is this point that needs attention if a crop of fruit is to be obtained the year following planting. Care must also be exercised so that the crowns are not buried too deeply, and the roots should be spread out well in the soil, which needs to be made firm around them. The point of the crowns whence the roots spring should be just level with the surface of the soil after the operation of planting is completed.

We have already indicated that this bed has given us fruits for four weeks, and promises to do so for at least three more. The secret of this is that the plot was divided into three equal portions, and these were planted respectively with Royal Sovereign, The Bedford, and Laxton's Latest. The first named was the first to ripen, and a right royal crop did it yield. Before it had finished, The Bedford was giving us its earliest fruits and, if anything, in greater abundance than the first named. At the time of writing we are still gathering from the plants, and Laxton's Latest has just ripened its first fruits. Royal Sovereign is too well known to need description. The Bedford is an excellent variety, with rather rounded fruits and white flesh. It is much sweeter than Royal Sovereign and a good dessert Strawberry. Laxton's Latest produces enormous fruits, which, in spite of their size, are solid and of good brisk Pine-apple flavour. They are dull crimson in colour, but the flesh when broken is bright scarlet crimson and very luscious. There are, of course, many other good Strawberries, but for the average garden these three would suffice and keep up a succession over a long period. Plants of them are obtainable

A BEAUTIFUL SPECIMEN PLANT OF SCHIZANTHUS PINNATUS, OVER SIX FEET IN HEIGHT.

small gardens, i.e., those from a quarter of an acre to an acre in extent, and where much of the work is done by the owner, the Strawberry-bed is too often one of the most neglected features. We have wondered, too, why it is that market-growers of this fruit pin their faith solely to one variety, usually Royal Sovereign. The result of this is that for about a fortnight, especially during a good season like the present, the market is glutted with fruit, after which very little is obtainable, and that at a greatly enhanced price. The late Strawberries always make better prices than mid-season ones,

from any of the fruit nurserymen now advertising in our pages, and no time should be lost in preparing a bed and getting the young plants established.

SEASONABLE NOTES ON FRUIT.

Strawberry-Beds. Here is an excellent rule to apply to the Strawberry-bed: Clean it thoroughly immediately the crop is harvested. It is too common for this task to be deferred until late in the summer, and some cultivators even neglect it until the autumn. Any delay results in loss. The instant the fruit is pushed the nets should be withdrawn, every weed pulled or cut out, all runners not wanted for propagation removed, all leaves that show the slightest indications of disease picked off, and the bed left clean and tidy. One thus gives light and fresh air the chance to find their way to the crowns of the old plants as well as to the runners rooting in small pots, squares of turf, or the soil between the rows. The benefit is immediate as far as the runners are concerned, and is postponed as far as the crowns are concerned, but it is there, nevertheless.

Layering and Planting.—In connection with the formation of new plantations of Strawberries, two important tasks present themselves to the grower, and both are of considerable urgency. By fixing down the plantlets or runners we secure fresh stock for extensions, and it is impossible to start too soon. The present is well on the late side; but if stock is short, go ahead, and finely-rooted plants will be at command for planting soon after the middle of August. Take the first or second runner on the strig and remove all beyond. Attach securely to the soil in small pots or to the soil of the alleys, see that it never becomes dry, and progress will be quickly apparent. The important task of planting ought to be in full swing. Bear in mind that the life of a Strawberry-bed is a short one—it rarely exceeds three years, and is often shorter—and determine that it shall be a profitable one. To that end do not spare really first-class cultivation of the soil, and see that the top is beautifully friable as a result of excellent mechanical culture.

Budding.—The majority of amateurs restrict their experiments in this interesting process to the Rose garden, but they should also have a try with fruit trees. All kinds respond perfectly, and budded trees are invariably the equals, and oftentimes the superiors, of those that are grafted. The essential points to be observed are identical with those applicable to Roses, and need not, therefore, be repeated in this column. It is certain that the amateur who has successfully budded his own fruits will be a proud man.

Watering and Feeding.—Although it is customary to restrict the watering of fruit to the trees growing on walls, it pays to extend the operation to the trees in the open quarters of the garden during periods of drought. When these come, spare no efforts to thoroughly soak the soil to a depth of 3 feet, and rest perfectly assured that

the results will amply justify the time and attention that have had to be devoted to the task. As a rule, two soakings will suffice, but a third must not be withheld if it is deemed necessary. It pays, too, to supplement the clear water with liquid manure in the majority of instances, and especially so with the trees on walls. Whatever may be done in this direction must follow the water and not precede it, since there is always an element of danger in the application of liquid manure to dry soil, and this may be taken as applicable throughout all departments of the garden.

Insect Pests.—The importance of maintaining a sharp watch for insect attacks cannot possibly be over-estimated. Each tree ought to be subjected to a close scrutiny at least once a week, and preferably more frequently, because the earlier an infestation is observed the easier will eradication

A LARGE BED OF THE MOONLIGHT BROOM, CYTISUS SCOPARIUS SULPHUREUS, A BEAUTIFUL SHRUB FOR POOR SOIL.

prove to be. Most of these pests multiply with wonderful rapidity, and neglect of inspection for two or three weeks may result in a tree or trees becoming absolutely smothered with an enemy which will suck out the life juices and thus prejudice the crop of this year as well as that of the future. Whenever insects are found the shoots ought to be well syringed with some insecticide, using a syringe with a spraying nozzle, and preferably one that has a bend or elbow at the end. This enables the operator to force the liquid well on to the under sides of the leaves, a position usually selected by pests for their attacks. Often the foliage is badly curled and it is no easy task to reach the insects, hence more than ordinary care is necessary if a complete eradication of the pests is to be effected.

TREES AND SHRUBS.

THE MOONLIGHT BROOM.

(CYTISUS SCOPARIUS SULPHUREUS.)

Of the many Brooms in cultivation, none is more worthy of a place in English gardens than the Moonlight Broom, and one fails completely to understand how it is that it is seldom seen and is comparatively little known, save to the few who are aware of its great beauty. For planting in open woodland or on banks of light soil it has few equals, the sulphur yellow flowers being produced in such profusion during May and June that they appear to illuminate the surrounding landscape. Any place where the common Broom or Gorse thrives will suit the requirements of the Moonlight Broom. It is not a tall-growing plant of leggy habit, such

alas! as many Brooms are, but it is of a more or less drooping nature, flowering from the uppermost branches to the ground, as shown in the accompanying illustration. The Moonlight Broom is one of the many varieties of the common Broom, *Cytisus scoparius*. It is as hardy as the Gorse, and so exceedingly beautiful that no garden can be complete without it.

SHRUBS FOR DRY SOILS.

THE ROCK ROSES.

The Cistuses or Rock Roses are excellent plants for clothing dry, sunny banks, for they are usually of compact growth and cover somewhat unfavourable positions with greenery for nine months of the year, whereas during the other three months the foliage is in some cases almost hidden by flowers, especially during the early part of each day. The doubtful

hardness of a number of the species may be urged against them as a reason why their culture should not be general, but as they are so easily propagated, both by seeds and cuttings, this need not be accepted as a serious argument, for if a few young plants of the more tender kinds are reared each autumn in anticipation of a severe winter, they take up little room if stored in a cold frame, and come in to fill the vacancies caused by deaths from frost. Fortunately, young plants grow rapidly when planted out; therefore they soon become large enough to furnish gaps. There is one point in their culture which needs consideration, that being the provision of permanent positions when they are first planted out, for if planted in nursery quarters and afterwards transferred elsewhere a great many will die, or be seriously injured, however carefully the work is accomplished. Therefore if the position is not ready for the plants when they require planting, place them in larger pots until they can be put in their permanent position. When plants are becoming crowded, a number should be cut out and destroyed rather than try to transplant them. Cuttings of many kinds taken during summer and inserted in sandy soil in a cold frame root quite readily, while seeds of other kinds, collected when ripe and stored in a cool room until February, germinate in a few days if sown in pots of sandy soil in a little heat.

Any ordinary garden soil is suitable for *Cistuses*, even that of a light, gravelly character, providing it is dug deeply previous to planting and the plants are kept watered until established. In fact, rich soil is to be avoided, for it encourages rank growth, which is more liable to injury in winter than that of a sturdier character. Practically no other pruning is required than the removal of the flower-heads as soon as flowering is over, except a few which may be required for seeds. Where a large group cannot be formed, it is usually possible to find room for a few plants; if nowhere else, then on the rockery or wall, for they are excellent for rockery planting. It is, however, when seen as a large mass that their beauty is most apparent.

Between 1825 and 1830 the botanist Robert Sweet prepared a work on the *Cistinea*, and in that book full descriptions of most of the *Cistuses* grown at the present time are to be found, in addition to descriptions of other showy kinds which appear to have been lost to cultivation. Of the numerous species and hybrids, the following are specially worthy of note:

***Cistus albidus*.**—This is a rather tender species from South-West Europe, characterised by greyish, lance-shaped leaves and bright rose-coloured flowers.

C. corbariensis is considered to be a hybrid between *C. populifolius* and *C. salvifolius*, and it

is one of the hardest sorts. Growing about two feet high, it forms a compact bush bearing ovate or cordate leaves and white flowers. The latter are about one and a-half inches across, and from one to five flowers appear together from the points of the branches.

***C. cyprius*.**—This is a native of Cyprus and resembles *C. ladaniferus* in foliage and growth, but there is a difference in the arrangement of the flowers. It forms erect branches 3 feet to 4 feet high, bearing rather narrow, lance-shaped leaves, which are dark green above and silvery beneath.

A LARGE AND WELL-FLOWERED BUSH OF THE VINE-LEAVED ABUTILON IN A SOMERSET GARDEN.

The flowers are from 3 inches to 3½ inches across, white, with a rich crimson blotch at the base of each petal, several flowers being borne together in each inflorescence. Branches, leaves and flower-stems are rather glutinous.

***C. ladaniferus*,** a native of South-West Europe, differs from the last named by its flowers appearing singly instead of several together. In other respects they are much alike.

***C. laurifolius*,** the hardest of all the *Cistuses*, is found in the same region as the last named.

It grows upwards of six feet high, is of rather loose habit if not pruned a little when young, and is easily recognised by its ovate leaves, which are 3 inches or more long, up to 1½ inches wide, and dark green above and silvery beneath. The white flowers are between 2 inches and 3 inches across and are borne with considerable freedom.

C. Loretii is one of the sturdiest and most beautiful of all. Forming a bush at least 4 feet high and 4 feet through, it is well clothed with rich dark green leaves and bears terminal heads of large white flowers, each petal having a rich crimson blotch at the base. It is fairly hardy and is of hybrid origin. *C. ladaniferus* is said to be one of its parents.

C. monspeliensis is another hardy species from the Mediterranean region. Forming a bush 1½ feet to 2 feet high and 2 feet to 3 feet across, it represents a perfect globe of white flowers during early summer.

C. recognitus is a hybrid between *C. laurifolius* and *C. monspeliensis*. It is hardy and of vigorous growth.

Of the coloured kinds *C. villosus* is one of the hardiest. It has greyish leaves and rosy purple flowers. Several varieties of this species, such as *creticus*, *rotundifolius* and *undulatus*, are known, all of which have rose or rosy purple flowers. *C. tauricus* is another species with rose-coloured flowers, while perhaps the darkest coloured of all is *C. purpureus*. In this case the flowers have dark blotches at the bases of the petals. As a rule the species with rose or purple flowers are less hardy than the white-flowered kinds; moreover, they are somewhat more difficult to raise from cuttings; therefore care should be taken to save a few seeds each autumn. D.

THE VINE-LEAVED ABUTILON.

Of choice flowering shrubs, the Vine-leaved Abutilon, *A. vitifolium*, is one of the most interesting. A native of Chili, it is not hardy in very cold districts, but in many parts of the Southern Counties it can be successfully grown and flowered, providing it is afforded shelter from cold winds. In the Western and South-Western Counties it flourishes quite in the open, and the accompanying illustration,

from a photograph kindly sent us by Colonel H. Moore, Higher Woodcombe, Minehead, Somerset, serves to show how freely it grows and flowers there. This shrub is growing between a fine bush of *Pittosporum* and a tall plant of *Ceanothus azureus*. The flowers of this Abutilon are pale lavender blue in colour, and the leaves resemble in shape those of the Vine; hence its specific name. It needs warm, well-drained soil, and, as already indicated, protection from cold winds in all except the most favoured districts.

THE FLOWER GARDEN.

DAFFODIL NOTES.

Lists.—Ever since the season began we have had them — "Oversea List," "Preliminary List," "Foreign and Colonial List," "Surplus List," "Abridged List" and so on. Many of us have purchased and our pockets have had no time to refill, when, lo and behold! the lists begin to arrive. I read in the papers the other day of an American millionaire who lamented that he could not get even with his income. All, however, that he seemed to be doing was to charter such inexpensive things as special trains, and then do a little journey of two or three thousand miles in a few days under the scheduled time of the fastest express. Should this meet his eye, might I suggest his becoming a Daffodil enthusiast. Judging from experience, it might help matters very considerably. I do not think I have ever met anyone who has been able to buy *all* that they wanted. "I must wait until Cræsus drops to nine pounds," or "When Challenger is five pounds I intend to buy a bulb." New Daffodils soon find the cupboard bare. Next week I intend to devote the whole of my notes to the question of purchasing for shows and show matters generally. August is the last month in which we can do this, for if the bulbs are not in the ground before the end of the month, one's chances of success are jeopardised. I am glad to think that would-be exhibitors will this year have as a help what they have never had before—the "Royal Horticultural Society's Daffodil Year Book" (to be obtained from the Royal Horticultural Society's Offices, Vincent Square, S.W., for the sum of half-a-crown). In this publication, among other things, will be found a detailed list of all the prize-winning flowers shown in London and at Birmingham in 1913. I remember from my pantomime days the refrain of a certain topical song which seems to meet the case here:

"What could you wish for more, my boys?
What could you wish for more?"

The best practical advice that I can give is, "Buy this Year Book, and order it at once." I hope it will be published very early in August. Then, having got it, "Study the lists carefully."

The Merodon.—I hear complaints from various quarters of the presence of this unwelcome visitor. That hot summer of 1911 appears to have "done the mischief." Ever since then we have had the merodons in considerable numbers. Mr. Stocks of Doncaster has been "on to them" again this year, and I fancy before long he is going to give us his new experiences in print. Meanwhile I would suggest soaking the bulbs in water for twenty-four hours if there are any quantity of them that are supposed to be affected.

Fanny Currey.—I have frequently asked residents in the South of Ireland if they knew Miss Currey, and two out of three invariably said, "Do you mean Fanny Currey?" This usage of the Christian name among men denotes a good fellow or a popular chap. Miss Currey is one of the best, and accordingly, now my meaning is

clear, I make no apology for heading this paragraph as I have done. We were all exceedingly sorry to hear of her illness, and her enforced absence from all our spring shows made a gap in our ranks; but we hoped she would soon recover. I am sorry to say her recovery is but slow, and much to my regret I now learn that she is compelled to entirely give up her business. I remember Miss Currey once saying to me, "I don't think I have made many mistakes in the stocks I have bought." I do not suppose she has, for I always look upon her as a woman with great critical taste and business acumen. She has got some splendid things at The Warren Gardens, Lisnace, and her interesting side offers will well repay a perusal. I should like both amateurs and traders to rally round and buy up her remaining bulbs. There is something in her collection to suit everyone, only remember "first come, first served." I always associate the name of Fanny Currey with

see more and more people take it up. The choice of parents is so wide and the potentiality of the Narcissus family is so great that all its possibilities will not be exhausted for many a long day. There is here a mine of quiet enjoyment capable of finding a pleasant occupation for any number of willing workers. Again may I say, "Get the Year Book." JOSEPH JACOB.

ROCK AND WATER GARDEN.

A DAINTY BELLFLOWER.

(*CAMPANULA PUSILLA* MISS WILLMOTT.)

ON many occasions we have drawn attention to the merits of this charming Campanula—a dwarf variety with flowers of the softest silvery blue shade. It is one of the most beautiful of dwarf Campanulas, and

CAMPANULA PUSILLA MISS WILLMOTT, ONE OF THE MOST POPULAR VARIETIES FOR THE ROCK GARDEN.

those delicate-looking, ruffled, pure white trumpets White Knight, Lady of the Snows, Atalanta, Avalanche and Mrs. Robert Sydenham. But her taste was catholic, and among her other purchases were Challenger, Michael, Cræsus, Firetail, Warrior, and more recently still Crosheld's lovely scarlet-eyed Tara Ramee. I have said enough. It only remains for me to assure her of our deep sympathy with her in her enforced retirement.

Seeds.—The seed crop has not been a very large one. Both Mr. Engleheart and Mr. Walter Ware report large pods with but little in them. My own experience coincides with theirs. The latter ended up one of his letters to me something like this: "However, I expect there will be quite as many as I shall want." The truth is, it is a fairly easy matter to obtain seed, and as the fascination of seedling-raising is very great, I hope to

this year it has attracted more attention than usual at the summer flower shows, where it has been freely planted in the exhibits of alpine gardens. It is a profuse bloomer, producing masses of its dainty bells, being admirably adapted for growing in the crevices of old walls and between rocks and stones. One of the most effective ways of growing it is in the paved garden, where it will thrive in the chinks between the paving-stones. We have in mind a paved Lavender walk with this Campanula freely used. The study in pleasing tones of blue and grey is one not readily forgotten.

In the cultivation of Campanulas it is well to remember that all of them, more especially the alpines, love limestone. It is, for instance, on the grassy downs over chalk hills that the common Harbell, *Campanula rotundifolia*, grows so freely and flowers in wild profusion.

GENTIANA VERNA IN GRASS.

GENTIANA VERNA in the majority of cases is a difficult subject in the rock garden when planted in loose, open soil. The tufts will, as a rule, commence increasing satisfactorily, but they soon find their limit. Continued wet will often cause black patches in large tufts; then come ants and other vermin to work mischief beneath the protecting cover, earth-worms pull about the rootless new growths, and in a short time a proud tuft will look unsightly or perish altogether. *G. verna* is only truly enchanting when growing in masses, forming large colonies among the grass with hundreds of expanded blossoms on them; but how is this to be effected in the garden when every fresh effort to establish it satisfactorily ends in the same failure?

I had almost given up its culture as a bad job; but how can we do without this most beautiful gem of early spring? No rock garden would be complete without it. After racking my brains for a successful method of growing the plant, I hit upon a plan which I thought worth trying. "Back to Nature," I said, and as in summer on our excessively dry soil a good close lawn, without spending a great deal of labour over it, not to be obtained, I resolved to beautify my shabby grass plot—for the springtime at least, when it is still fairly green—by trying to establish *G. verna* thereon. It grows and flourishes to perfection on meadows and along the roadside outside my garden; why should I not get it to grow on my lawn? Instead of challenging fresh disappointments by trying it over and over again in the rock garden, I consequently started, three years ago, to sow seeds all over the grass in the autumn, and repeated the process every autumn following. This year I had the triumph of a first result in twenty-eight nice flowering tufts, and on a close search I discovered, to my intense joy, that the whole of the grass was studded with young seedlings, so that I feel justified in presuming that I shall shortly beat Nature outside my garden by a veritable carpet in blue on my own grounds. *G. verna* requires a fibrous body to root in and a clothed surface to push its young growths into, both of which can only suitably be given to it among a fairly loose grass sward.

On a close, velvet lawn, of course, success would scarcely follow. One should therefore keep a grass plot in a somewhat starved condition for the purpose. It is a mistake to suppose that *G. verna* requires a rather moist or even a wet position. The soil here is excessively dry, and in summer sometimes so utterly parched that he might be considered—by anyone not having seen it thrive and luxuriate in such positions—a bold man who attempted to prepare a similar plot for its culture in his rock garden. True, the plant also occurs in moist and even in wet places, but never there to such perfection nor in anything like such numbers.

By the annual sowings the stock is always being replenished. The same takes place in Nature. No doubt many tufts perish there annually, and yet invariably, in every spring, meadows and roadsides are replete with their hundreds and thousands of the blue stars of *G. verna*.

Planegg, Bavaria.

E. HEINRICH.

THE KITCHEN GARDEN.**SEASONABLE NOTES ON VEGETABLES.**

So far the season has not been an ideal one for vegetables, especially in cool districts and where

addition to good quality, and where plants in heavy soils are not making satisfactory progress, the cultivator should pass some well-decayed leaf-soil through a 1-inch mesh sieve, mix a small quantity of rotted manure and road scrapings with it, and top-dress the Celery, putting the mixture on in a layer about one inch deep. New roots will soon permeate the compost, and then the top growth will be much freer. When the roots are numerous, judicious feeding will help matters considerably.

Dwarf or French Beans.—A late sowing of these should be made in one of the warmest borders in the garden. Drop the seeds 9 inches apart in shallow drills 18 inches asunder; single rows are better than double ones. If the soil is very dry, pour water in the open drills before sowing the seeds and covering them; then germination will be rapid. By adopting this plan I have had some of the best crops of the season, the pods being straight and exceptionally tender.

Open-air Tomatoes.—The soil around the roots must be maintained in an even state as regards moisture, otherwise many fine fruits may be lost through splitting; when split, decay soon sets in. No feeding should be done except when the soil is moist. In order to get all the fruits ripened which are now setting on the plants, cut off the tops beyond the last-formed truss of fruits. When swelling, feed the plants regularly, and all the fruit will mature, be solid and heavy in regard to size.

Beet and Carrots.—The first named is a very tender root, and when the workman is engaged in hoeing between the rows he should be very careful to avoid stabbing the crowns with his hoe, as when bruised in any way the root bleeds considerably, and then the colour is pale instead of being deep and rich when boiled. Carrots should be eased up in the soil when lifted for use; if forcibly pulled they are bruised, and the marks show pale in colour when the Carrots are cooked and placed on the table. Both kinds of vegetables grow best when the surface soil is kept loose by frequent hoeing and free from weeds, also when the plants are exposed to all winds that blow.

Seakale and Rhubarb.—Flower-stems are more numerous on these

plants in some seasons than in others. They are not plentiful this year, but the cultivator should cut off every stem he can find, but not too low down. As long as he removes the portion bearing flowers, the object aimed at will be gained.

Asparagus.—The rule is generally observed that when Peas are plentiful the cutting of Asparagus ceases. It is never advisable to continue the cutting of Asparagus for too long a time, however fine the produce may be; but when cutting does stop, the beds are often neglected and weeds grow apace. The best policy is to keep the beds clean all the year round.

Avon.

THE NEW ROSE, MRS. F. W. VANDERBILT, AWARDED A GOLD MEDAL AT THE NATIONAL ROSE SOCIETY'S PROVINCIAL SHOW AT GLOUCESTER.

the soil is of a cold, clayey nature. Even in medium heavy soils I learn that seeds of Carrots, Onions, Beet and Peas failed to germinate. The plants from later sowings are healthy and very promising, but much later than usual.

Celery.—The mancrop plants in light soils are now growing freely. Those in clayey ground are just beginning to produce new central leaves; but, fortunately, these new leaves and stalks appear to be very strong. I have seen plants grown in a cold, clayey soil make very little progress in cool summers, and when the time came to use them the sticks were very small, but quite solid. However, the cultivator wants a fair bulk in

GARDENING FOR BEGINNERS.

HOW TO INCREASE THE SIBERIAN FLAG (IRIS SIBIRICA).

EVERYONE should make an effort to grow this plant, for there are few, if any, more beautiful yet easily-grown members of the Iris family. While *Iris sibirica* will grow in most soils and positions, those to avoid are dry and shaded spots overhung with trees. The greatest success may be looked for in a rich, moist soil and one where plenty of sunshine reaches the plants. Though few readers may be able to find it in their gardens, perhaps the happiest of all spots for this Iris is by the side of a pond, stream, or lake, and we refer readers to the illustrated notes which appeared in last week's issue on this subject. In association with water the Siberian Flag makes a glorious display during the second half of May and in early June. But there are other ways of attaining success with this Iris. It may find a place in the mixed border, the pride of hundreds of town and suburban gardens. Should the soil be rather poor, or the season a dry one, mulch the plants with some old rotten manure, and water liberally during dry periods.

Propagation.—The usual method of increase is to lift and divide the clumps or tufts during July soon after flowering, unless it is desirable to save the seeds, in which case propagation must be deferred until the seeds are ripe. Great care is necessary when dividing the clumps not to break

the roots, or, at my rate, to do as little damage to them as possible. A spade is sometimes used to chop a clump such as that shown in Fig. 1 in pieces; this is drastic treatment, from which the plants will not recover for a couple of years. The right way to divide clumps of the Siberian Iris is shown in Fig. 2. A couple of hand-forks are placed back to back in the centre of the clump and pressed outwards. This will divide the clump in two; these are again divided with the forks in the same way till the pieces are considered a suitable size to plant. It naturally follows that the larger the pieces for replanting, the quicker they will produce a good display of flowers. Fifteen inches apart is a suitable distance to plant the divided pieces, but it may vary from 1 foot to 1½ feet at the discretion of the cultivator. Water several times a week after planting till established. A mulching of flaky leaf-mould will assist in keeping the ground moist, and damping over the leaves after a hot, sunny day will be beneficial.

Seeds also form a ready means of propagation, and should be sown as soon as ripe. It, however, takes about three years to flower this Iris from seeds; consequently, except with the idea of raising new varieties, the propagation by division of the tufts is preferred.

The Siberian Flag grows 2 feet to 3 feet high, forming in time large clumps or tufts of tall, slender growths rather suggestive of a vigorous grass. The flower-spikes, which push up during May, bear a succession of showy lilac blue flowers, which are prettily veined. In addition to the type there are several distinct and attractive varieties. Perhaps the best of these are *orientalis*, with larger, deeper-coloured flowers; *orientalis* Snow Queen, a large ivory white variety of exquisite beauty; *alba*, a useful white variety of the type; *Baxteri*, blue and white; *Distinction*, violet and white; *George Wallace*, light blue, flaked with white; and *superba*, a tall variety with violet blue flowers.

HOW TO PROPAGATE HYDRANGEAS.

The *Hydrangea* is not a difficult plant to grow when the cuttings are well rooted, but rooting them is sometimes a task not easily accomplished. For greenhouses and conservatories the dwarf plants, bearing one truss of flowers, are extremely suitable. To obtain

2—THE CORRECT METHOD OF DIVISION IS BY THE AID OF HAND FORKS.

such the cultivator should put in cuttings of fairly well-ripened wood at once, and keep them growing to one stem. Each cutting should be about six inches long and possess at least two fully-developed leaves. The leaves from the lowest joint must be cut off, also the stem immediately below that joint; then the cutting will be duly prepared for insertion. Put one cutting in a small, deep pot in a loamy, gritty compost, making the soil very firm around it and settling the soil by watering it through a fine-rosed watering-can. The best position for the cuttings to root in is a cold frame with lightly-shaded glass. Keep the soil in a medium state of moisture. See to the efficient drainage of each pot. Avon.

SPINACH BEET.

To the amateur with but a limited garden accommodation and the desire to grow a few vegetables, I know of nothing more remunerative than a crop of Spinach Beet, which will yield regular pickings over a lengthened period. From seed sown at the end of April I have been picking for some weeks, and am likely to continue until the spring. Of course, as the season advances, the production of new leaves will be slower. Where there is a space of ground available, a crop of this Spinach Beet may now be sown, and it will then come into bearing early in the autumn, or even before summer has really left us, and continue till the spring. The ground should be deeply dug, and must be in good condition. If necessary, some manure may be incorporated when digging, but if it is in good tilth no fresh manure will be needed. The seed should be sown in drills from 1 foot to 15 inches apart, and when large enough thin out the seedlings in the rows to within 3 inches or 4 inches of each other. Unlike the common Beetroot, this variety devotes its energies to the production of leaves, which may, when large enough, be picked off and cooked exactly like the common Spinach. The plants must not be picked too bare at any time, and they will then continue to rapidly develop new leaves. H. P.

1.—A CLUMP OF THE SIBERIAN FLAG NOW READY FOR DIVISION.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Watering.—Naturally, freshly-planted trees and shrubs are the most likely to suffer from drought, and wherever possible, in addition to watering at the roots, they ought to be syringed overhead as often as possible in the evening. Continual working of the soil will do much to conserve the moisture in the shrubberies; but where shrubs and trees have been planted a long time, the soil will probably have become very hard to a great depth; hence there will not be the amount of reserve moisture as in freshly-dug or trenched ground.

Mulching.—This will do much to minimise the effects of drought, but do not put it on a hard, dry surface. Break the surface soil and give a good watering, put the mulch on and again water. Such treatment will probably save the lives of many trees and shrubs which are now hanging in the balance.

The Rock and Water Garden.

Many of the plants, having gone out of flower, will need trimming in somewhat, and all flower-stems and seed-pods should be removed, these latter if left on proving a great tax on the energies of the plants at this season.

Lily Ponds must be kept quite free of the various weeds which are apt to infest them, as these often grow to such an extent that they quite smother the plants which one wishes to see do well. Small ponds are easily kept clean by the use of the drag or rake, but larger ponds present more difficulties, and an old flat-bottomed boat or punt may have to be requisitioned from which to rake out the weeds.

The Flower Garden.

Border Carnations.—These should soon be making a good show, and if they are not already bursting their flower-buds, a good syringing overhead may be given occasionally. This will keep down thrips, which are often troublesome during a dry season; also a good soaking of manure-water just as the blooms are opening will increase the quality considerably.

Edging Plants used in summer bedding may require pinching to preserve a good outline to the beds, and Pyrethrums, Coleus, Fuchsias and Iresines should be regularly gone over, keeping them pinched back far enough from the edge of the bed to allow the machine to run along without damaging it.

Plants Under Glass.

Cleaning.—If the syringing will not keep down insect pests, then sponging or spraying must be resorted to, and paraffin emulsion and XL All are both excellent insecticides when used with care.

Palms and Selaginellas must also be kept well supplied with water, and, what is very important, they must be kept well shaded, as, once they turn yellow or get burnt by the sun, it will take a long time to restore them to their natural condition again. Clay's Fertilizer is a good manure for either of these subjects.

Cinerarias, Primulas and Calceolarias that may have been raised about the time recommended in the calendar and subsequently pricked off into pans or boxes should soon be ready for potting off into 3-inch pots. Primulas require a little more warmth in the early stages of growth than the other two subjects, but the soil to be used and treatment generally is on similar lines. After potting, shading in each instance is necessary, but when nicely rooted in the pots both Calceolarias and Cinerarias may have the lights partially removed on fine, dry nights. This will produce a stockiness in growth not obtained in any other way.

The Kitchen Garden.

Spring Cabbage.—Towards the end of the week a sowing of Cabbage should be made, to be followed fourteen days later by another sowing to provide the main batch. If the soil is dry, the drills should be watered before sowing. This will facilitate germination, and is much better than having to water the young seedlings as soon as they are through the soil.

Endive.—Take the earliest opportunity of planting out a good batch of this salad for autumn and winter use, and if the beds are planted about five feet to six feet wide, lights may be placed over them as desired. Needless to add, the plants will want well looking after as regards water if they are not planted during a showery time.

Fruits Under Glass.

Early Vines.—Vines from which all the fruit has been cut and again intended for early forcing next season should, as far as possible, be allowed to rest. Though the roots must on no account get unduly dry, too much moisture is apt to keep the Vines growing too long. For this reason also all syringing overhead should be stopped, though an eye must be kept on the foliage to see that insect pests do not get a footing; if so, an insecticide must be used to check them.

Peaches also must be treated in much the same way, but here any neglect of water at the root will be followed by serious results. During excessively hot weather I think it is desirable to apply a little shading to the glass, as Peaches and Nectarines, especially the early varieties, are apt to get over-ripe, and this I believe to be one of the causes of bud dropping in the early spring.

Hardy Fruit.

Strawberries.—Continue layering the later varieties of Strawberries till sufficient has been done to cover all possible requirements. Givon's Late Prolific on our heavy soil is the best cropper we have. It does not give all its fruit at one time, but covers a particularly long season. Early layers may be taken off as they become sufficiently well rooted, and if stood in a semi-shady position for a few days there will be no tendency to flag.

Old Plants that have served their purpose should be cleared off the ground, or, if there are no crops near by, all the rubbish may be burnt and the ashes spread over the surface again. Plants that are being grown on for another year should also be trimmed and the rubbish cleared away; but if the weather is dry, it is not advisable to take the straw off for a time, or the plants may suffer, and it is a good plan to give them a thorough watering. This will revive them somewhat after carrying a heavy crop.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Stock Lobelias.—The best way to raise a stock of Lobelia is to pot up a certain number of plants of each variety at planting-out-time. These stock plants should not be allowed to flower, and to prevent this the tops of the plants should be cut over two or three times during the growing season.

Chrysanthemums.—Attention should be given to tying as growth proceeds. Some stimulant may now be given to the plants, and the hoe should be kept going among them.

Herbaceous Plants.—Attention must still be given to the tying of Asters and other autumn subjects, care being always taken to avoid stiffness in carrying out the operation. All decayed flower-stems should be cut away as the various subjects go out of bloom. This is a good time for relabelling, as it is easy just now to verify the identity of any variety of which one may have been in doubt. This reminds me that in the calendar some months ago I was bewailing the disappearance of the Aeme Label Rest. I now find that I was in error, and that this excellent device is still obtainable in three sizes from any leading Northern nurseryman.

Sweet Peas.—From now onwards is the period when feeding is required. This, however, is often overdone, proving a prolific source of "streak." "Little and often" is a safe rule. Those who possess soot or old fowl-manure require nothing else. For the rest the market is plentifully supplied, as witness the advertisements in THE GARDEN from time to time. Keep all spent blooms scrupulously picked off twice a week.

The Rose Garden.

Disbudding.—Those who have been catering for late blooms by planting young stock or by

growing in rather shaded positions must practise disbudding if they would have blooms of high excellence. The first blooms are generally the finest, but one must have regard to the time when the blooms are wanted. This specially applies to exhibition blooms wanted for a particular date. Of course, a bloom can always be retarded for a week or more by means of shading.

Budding.—This work is rightly mostly relegated to the nursery experts in these days of specialising. Still, many private growers, especially amateurs, like to try their hand at the work, and there is no reason why they should not. Stocks and buds being available, all that is wanted is a good eye and deft fingers. T budding is the most popular system. Care should be taken not to damage the cambium on the stock, either when lifting the bark or inserting the bud. The more quickly the operation is performed the better, as the cambium is very delicate and exposure to the air soon injures it.

Plants Under Glass.

Layering Malmaison Carnations.—Although now put somewhat in the shade by the Perpetuals, the handsome blooms of the Malmaisons still find many admirers. It is now fully time that layering was proceeded with, and a cold frame partly filled with soil is the best place for the work. Turn a few old plants out of their pots and plunge them in a reclining position. The work of layering can then be proceeded with, using some fibrous, sandy loam for working in about the layers. Give a good watering when the operation is completed and shade lightly during bright sunshine. Keep the frame rather close till roots are emitted.

Cinerarias.—These must be potted on as necessity requires, using a rich, light soil. Unless the frames are facing north, the pots should be plunged in coal-ashes or other cool, porous material. Shade from bright sunshine, and if the leaf-mining maggot appears, spray occasionally with Quassia extract.

Primulas.—The remarks on Cinerarias apply generally to such Primulas as sinensis, obconica and malacoides, except that Primulas enjoy a rather finer medium than the Cinerarias. It should be borne in mind that some persons cannot operate with P. obconica barehanded with impunity.

Propagating Edging Plants.—A fresh batch of such edging plants as Panicum variegatum, Tradescantias and the trailing Coleus should now be rooted to keep up a fresh supply during the autumn and winter months.

Fruits Under Glass.

Shading Black Grapes.—It is now a generally accepted truth that black Grapes are frequently more or less injured by being exposed to the full blaze of the sun, and careful cultivators who have had such an experience afford the crop a slight shading.

The Hardy Fruit Garden.

Peaches.—Earwigs often prove troublesome at this season. If lengths of Beanstalks are adjusted among the shoots, the enemy will take shelter in these during the day. Go over the traps in the morning with a bottle, partially filled with water, in one hand. With the other insert one end of the Beanstalk in the mouth of the bottle and blow smartly into the other end of the hollow stalk. This will dislodge the enemy and drive him into a watery grave.

Morello Cherries.—After seeing to it that all the requisite wood is laid in and the remainder cut out, the trees should be netted.

The Vegetable Garden.

Leeks.—If the hoe is run lightly in between the rows, it will partly earth-up the earlier planting if the operation was carried out as advised in the calendar at the time. Planting may still be done to obtain Leeks for spring use on quarters which have been occupied by early crops.

Vegetable Marrows.—Continue to thin out and regulate the shoots, and pollinate the female blooms as they appear. The fruits should be cut at an early stage, else they deteriorate in quality and rob the succession fruits.

Peas have so far done splendidly with us. If drought sets in, however, watering must be the order of the day. Senator is still greatly prized here.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

OBITUARY.

ROBERT SYDENHAM.

It is with the deepest regret that we have to record the death of Mr. Robert Sydenham, head of the firm of Robert Sydenham, Limited, Tenby Street, Birmingham, which occurred suddenly on Saturday morning last. Mr. Sydenham attended his office in the usual way and was taken ill about 11 a.m., and expired almost immediately. It was only on Thursday of last week that we had the pleasure of meeting him at the National Sweet Pea Show, and also at the dinner of the judges and committee held at the Hotel Windsor in the evening, when the last toast proposed was that of Mr. Sydenham. The news of his death will come as a great shock to horticulturists in all parts of the world, as there were few phases of gardening that he did not take an interest in.

Born at Salisbury in 1848, his career in the horticultural world has been a most remarkable one. Up to the year 1881 he was actively engaged in the wholesale jewellery business of Sydenham Brothers, and it was in that year he disposed of a few surplus bulbs from his garden among his friends, little thinking at the time that he was laying the foundations of a business which to-day is one of the foremost in the country, and which a year or two ago dealt with nearly thirty-nine thousand bulb and seed orders in one season. A year or two ago Mr. Sydenham decided to turn his business into a private company, and with his characteristic generosity allotted shares to his employes, his object being not to raise additional capital, but to give a direct interest in the business to those members of his staff who had been with him for many years. Up till the time of his death he, however, still retained full control as governing director. The active interest that Mr. Sydenham took in the Midland Daffodil Society is known the world over, and to his personal and generous support the success of that society is largely due. It was his custom for some years to entertain the judges and numerous friends at dinner at the Grand Hotel, Birmingham, on the evening of the first day of the Daffodil Show, and at these dinners he gathered together Daffodil experts from all parts of the United Kingdom, the Continent, and at times from New Zealand, Africa and other parts of the world.

Sweet Peas were a favourite flower of his, and he took a very active interest in the affairs of the National Sweet Pea Society, occupying the presidential chair last year. The portrait reproduced here portrays him in a characteristic attitude among the National Sweet Pea Society's trials at Sutton Green. His little book, "All About Sweet Peas," was a publication that he took very great pains to keep as up-to-date and useful as possible, and many lovers of this flower have found it of great interest and value. He took a very keen interest in the Horticultural Club, and, indeed, it would be impossible to name any phase of gardening that did not, at some time or other, receive support from him. It would be difficult to mention any man who enjoyed a wider circle of friends in the horticultural world. His genial personality made friends of all who came into contact with him, and his generosity was never appealed to in vain. As an indication of the friendship that existed between him and horticulturists generally, we may mention that he was usually referred to as 'Uncle Robert.' We numbered him among our personal friends, and, in common with many of

our readers, mourn his loss. To his widow and family we tender our deepest sympathy in their sad bereavement. The funeral took place at Lodge Hill Cemetery, Birmingham, on Tuesday, the 22nd inst., and many tokens of esteem, a large number of horticultural friends being present to pay a last tribute to a great and generous man.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Dendrobium Dearei McBean's Variety. From Messrs. J. and A. McBean, Cooksbridge, Sussex. This was removed before a description could be secured.

AWARDS OF MERIT.

Odontioda Thwaitesii Purple Emperor.—The name is descriptive of one of the largest of these hybrids, though the colour will not

THE LATE MR. ROBERT SYDENHAM.

appeal to all. From Mr. E. H. Davidson, Orchard Dene, Twyford.

Odontioda Cooksonii venustum. A brilliant ruby crimson having a white-margined lip and slight yellow crest. From Sir George Holford.

Paphinia cristata.—The sepals and petals are 3 inches to 4 inches long, acute and heavily lined chocolate on a white ground. From Messrs. Charlesworth.

Carnation Firefly.—A gloriously brilliant scarlet of the largest size and nicely perfumed.

Carnation Bookham White.—Handsome creamy white flowers of fine form. Both from Mr. J. Douglas, Great Bookham, Surrey.

Delphinium Mrs. W. J. Sanderson.—A single-flowered variety of intense blue colour and pure white centre. The contrast is very fine. From Mr. J. Sanderson, Eastfield Hall, Warkworth.

All the foregoing were shown before the Royal Horticultural Society on the 15th inst., when the awards were made.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

SLUGS AND CANTERBURY BELLS (*Colony*).—In watering the plants of the slugs with a solution of potassium permanganate, 1oz. to one gallon of water. Trapping may be of advantage.

FUNGUS ON CAMPANULAS (*A. S. T.*). The fungus on *Campanula stenocodon* is called *Coleosporium campanulae*. It is not liable to attack other plants than various species of *Campanula*, many of which are liable to be attacked, as are species of *Adenophora*. It is probably connected with a fungus which occurs on Pines early in the season, and passes from one to the other alternately. The only thing likely to be of much avail is to spray the plants with a rose red solution of potassium.

SWEET WILLIAMS AND EELWORM (*Woburnham*).—The Sweet Williams are badly attacked by the stem eelworm (*Tylenchus deva-tratrix*). When once the plant is attacked, nothing is likely to cure it, and the only thing to be done is to try to prevent the recurrence of the trouble in a succeeding year. We would recommend the immediate destruction of the affected plants by fire, so as to check the spread of the pest in the earth, to which it will go when the plant dies. The soil in the affected places should be treated with sulphate of potash in spring, or have a good dressing of kainit in autumn.

CALCEOLARIAS FAILING (*J. M.*). We recommend you to avoid growing *Calceolarias* again in the soil in which these have been growing. A fungus which inhabits the soil gains entrance to the plants through the roots, and does much damage where these plants are grown repeatedly on the same soil. There are other plants which may be used to give yellow effects, such as *Tagetes signata* *pinnata*, which are not subject to this disease, and can therefore be planted for a few years until the soil has become free from the fungus again.

WEED IN LILY OF THE VALLEY BED (*H. H.*).—The weed is the Dog's Mercury (*Mercurialis perennis*), and you will find it less difficult to eradicate than such as the Bindweeds or Goutweed. You will of necessity have to exercise vigilance and reduce the clumps of the Lilies to small size to ensure getting out all the roots of the weed. Having done this, you might still be troubled with seedlings, though from this cause alone there is no great occasion for worry. Any time from the latter half of September would be suitable for dealing with the Lilies.

CINERARIA MARITIMA AND POTENTILLAS (*N. E. L.*).—*Cineraria maritima* may be increased by cuttings of young shoots inserted in sandy soil in a close frame in spring, and by seeds sown in a warm greenhouse or frame in February or early March. Plants raised from seeds in February form useful specimens the first summer. The shrubby *Potentillas* do not require any regular pruning. As a rule, nothing is done to them until they become dense, then a little of the older wood is removed. They do not flower well until they are four or five years old. Spring-flowering *Spiraeas* do not require regular pruning, as is necessary with those which bloom during summer and autumn. They may be left unpruned for several years, then be lightly thinned or cut back if outgrowing their positions.

MISCELLANEOUS.

ERADICATING THE STINKHORN FUNGUS (*Rouder*).—We fear it is impossible to destroy the Stinkhorn fungus over a whole garden. We recommend you to thoroughly water the parts where it appears with a solution of 1lb. of copper sulphate to twenty-five gallons of water, but take care not to touch the plants.

JUDGING COTTAGE GARDENS (*A. S.*).—It is impossible accurately to judge cottage gardens and allotments, except by marks. Your best course will be to allow a maximum of twenty for order, neatness and system of cropping in combination; or twelve each for all flowers and all fruits; and of six each for every vegetable crop grown. You must be exceedingly careful not to point high in the first garden, or you will find trouble later.

COLD FRAME (*Wafford*). In a frame 6 feet by 4 feet you are not likely to grow many plants suitable for house-decoration. A vast number of subjects may be grown in a cold frame during the summer months; indeed, they are better there than in a warmer structure, but a heated house is necessary for them in winter. This applies particularly to *Cyclamen*, concerning which you enquire, but tuberous *Begonias* may be grown in a cold frame providing the tubers are wintered in a frost-proof spot. *Chrysanthemums* may be grown out of doors and protected by the frame when the nights get cold till the blossoms expand, but for this purpose the frame would have to be of considerable depth; in fact, too deep for other plants to be grown successfully therein. As the season is so far advanced, there is nothing that we can recommend for present sowing likely to give satisfactory floral returns before winter. The *Schizanthuses* are just now very popular as decorative plants, and seeds of these may be sown about the end of August. The resultant plants may be potted into small pots and wintered in the frame, taking care that they are covered during severe frost.

NAMES OF FRUIT.—*Miss Dombain*.—Gooseberry, Lancer; Currant, White Dutch.

NAMES OF PLANTS.—*T. C. Ashdown*.—Shrub, *Deutzia gracilis flore pleno*. Rose, *Rève d'Or*.—*Mrs. M. Matland Gardner*. Rose *Paul's Early Blush*.

R. E. S. 1. Jean Soupett; 2. Mrs. W. J. Grant; 3. Alfred Grant; 4. Kaiserin Augusta Victoria; 5. Dean Hole; 7. Beauty of Waltham; 9. Marie van Houtte. The others had fallen.—*Mrs. W. L. Barry*.—1. Louis van Houtte; 2. Helen Keller; 3. Lady Waterlow; 4. Baroness Rothschild; 5. George C. Waud; 6. Merville de Lyon;—*M. R. Touquet*.—*Medicago scutellata* (small-like); *Medicago eburnea* (hairy fruit).—*S. H. B.*
Placchia tanaetifolia.—*E. E. B.*.—*Anemone* species, specimen dried up.—*E. H.*.—1. *Campanula rotundifolia*; 2. *Sedum spurium*; 3. *Armeria maritima* variety probably *lauchiana*; 4. *Sedum Telephium*; 5. *Bocconia cordata*; 6. *Phragmites communis variegatus*; 7. *Polygonum cuspidatum*; 8. *Fuchsia macrostemma* variety; 9. *Rudbeckia* species, specimen too scrappy; 10. *Achillea Ptarmica* The Pearl; 11. *Helianthus autumnale pumilum*; 12. *Mertensia* species, send when in flower; 13. *Eryngium giganteum*; 14. *Chrysanthemum maximum*; 15. *Campanula persicifolia alba*; 16. *Chrysanthemum Parthenium* fl. pl.; 17. *Spirea Filipendula*.—*C. Lemuel Adams*.
Astilbe species; specimen too small for identification.
C. K. 1. *Sedum album*; 2. *Lysimachia vulgaris*; 3. *Astrantia major*; 4. *Sapina procumbens*; 5. *Inula orientalis*; 6. *Arrhenatherum bulbosum* variety variegatum.
—*H. G. G.*.—*Hieracium rubrum*.—*John Burn*.—*Habenaria bifida*.—*Miss McMustee*.—1. *Sedum Lydium*; 2. *Saxifraga triaurata*; 3. *S. geranioides*; 4 and 5. *S. Gemu* variety; 6. *S. acanthifolia*; 7. *Centaurea dealbata*; 8. *Achillea Ptarmica*; 9. *Lysimachia punctata*; 10. *Malva moschata*; 11. *Sidalcea malvaeflora*; 12. *Iris* flowers, decayed; 13. *Heuchera*, garden hybrid; 14. *Cephalaria alpina*; 15. *Artemisia paniculata*; 16. *A. spicata*; 17. *Calamintha grandiflora*; 18. *Origanum* species, send in flower.—*Hodius*.—*Tropaeolum speciosum*.—*E. S. H.*.—*Hemantus tigrinus*.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

At the fortnightly meeting, held at Vincent Square on the 15th inst., there was a smaller show than usual, and visitors were by no means plentiful. Some very fine exhibits were, however, staged, and special mention must be made of the beautiful border Carnations from Mr. James Douglas and the pot fruit trees from Messrs. J. Veitch and Sons.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. W. J. Bean, B. Crisp, J. Green, G. Reulhe, C. R. Fielder, J. W. Moorman, G. Gordon, J. Jennings, J. E. McLeod, J. Dixon, C. Dixon, A. Turner, C. E. Pearson, W. Culbertson, J. T. Bennett-Poe, E. H. Jenkins, W. P. Thomson, W. J. James, W. A. Bilney, E. A. Bowles, G. Paul and T. Stevenson.

Mr. James Box, Lindfield Nurseries, Hayward's Heath, arranged a gorgeous bank of the finest herbaceous plants, the group stretching from the entrance to the Orchard Annex. It was perhaps one of the finest groups of these plants ever staged, and being arranged on the floor, had a most telling effect. It is not easy to particularise when all is so good, though we may remark upon *Penstemon*s, *Phloxes*, *Glaucolias*, *Princeps*, *Astilbes*, *Iris*, *Kaempferi*, *Panther Lilies* and *Water Lilies* among the greater host of plants now in flower. The arrangement of the whole was good, the effect of quite an imposing character.

Messrs. Bunyard and Co., Maidstone, had a particularly good table group of herbaceous flowers, *Phloxes* of the best varieties, *Romneya Coulteri*, *Heucheras*, *Chrysanthemum maximum* in variety, the old-seedlet *Lychnis* and other good plants. There were some fine *Gaillardias* in the group, the blue *Scabiosa caucasiaca* being very good in colour.

Mr. Boward H. Crane, Highgate, N., had a charming set of *Violas* and *Violtetas*, the latter of quite fairy-like character and delightful in the extreme. Of the *Violtetas*, *Osyth* (yellow), *Laxima* (mauve), *Purity*, *Sulphurea*, *Rock Lemon*, *Mollie* (rich golden), *Adeline* (violet blue), *Maive Gem*, *Violetta* and *Vesta* (both of which approximate to white) were shown. For massing in beds these are simply ideal.

The group of herbaceous plants from Messrs. T. S. Ware, Limited, Feltham, was replete with good and seasonable flowering subjects, the best of the *Phloxes*, *Campanulas*, *Alstromerias*, *Gaillardias*, *Hollyhocks* and other good plants being noted.

Messrs. F. Smith and Co., Woodbridge, had a well-arranged group of hardy flowers, white and blue *Scabiosa* being very fine. Excellent *Phloxes* were also shown, and a goodly mass of *Lathyrus latifolius* The Pearl, *Chrysanthemum maximum* The Speaker is perhaps the largest of this fine race of flowers, and was particularly well shown. *Verbasinums*, *Gaillardias* and *Alstromerias* were alike good and well represented.

Colonel the Right Hon. Mark Lockwood, M.P., C.V.O., Romford, showed three fine fruiting specimens of *Thladanthe dubia*, the scarlet fruits being of the size of a hen's egg and most effective.

Messrs. G. and A. Clark, Limited, Dover, showed a capital collection of herbaceous cut flowers, making a fine central group of the pure white *Carnation Downer's Pride*. The variety has not the merit of great fragrance, but to purity and freedom would, we think, be hard to beat. It was the finest plant in a goodly group.

Messrs. H. P. May and Sons, Edmonton, displayed a miscellaneous group of greenhouse Ferns, such genera as *Polypodium*, *Nephrolepis* and *Gymnogramme* being among others, well represented, Messrs. May also

exhibited a splendid group of standard-grown *Fuchsia Coralie*, a brilliantly-flowered triphylla hybrid of much merit.

Messrs. G. Bolton and Son, Buntingford, Herts, staged a good table group of *Roses*, such as *Melody*, *Lyon*, *Mrs. A. Munt* (cream), *Richmond*, *Mrs. Aaron Ward* (very pretty in the bud state), *Hugh Dickson* (very fine), *Rayon d'Or* and *Avoca* (the last two being particularly fine). *Mrs. A. Tate* was also good.

Messrs. William Cutbush and Sons, Highgate, N., displayed a table group of miscellaneous greenhouse plants, *Justicia carnea*, *Hydrangeas*, *Dracaenas*, *Caladiums* and *Lilies* all being well shown.

Messrs. Dobbie and Co., Edinburgh, had a very fine exhibit of new Sweet Peas, novelties chiefly for 1915, in King White, Early Cream, Blue Picotee, New Margin and Ruby Palmer were among the more distinct, though many more, equally so, were only under numbers at present.

The Guildford Hardy Plant Nursery had a mixed group of hardy cut flowers, *Eryngiums* and *Inulas* being prominent.

Hobbies, Limited, Dereham, had a small yet choice group of *Roses*, *Dream*, *Effective*, *Pink Pearl*, *Rayon d'Or* and *Lemon Queen* (a nearly pure white flower of large size) being among the more important.

Mr. G. Reulhe, Keston, Kent, had a mixed group of alpinos and shrubs, together with many choice *Lilies*, a large bush of *Desfontainea spinosa*, with bell-shaped flowers of scarlet and gold, claiming immediate attention, *Veratrum nigrum* and *Romneya Coulteri* were also good outstanding features.

Messrs. William Fells and Son, Hitchin, had a rockwork exhibit on tabling, *Campanula Stansfeldii* and *Oenothera eximia* being among the more prominent subjects.

Mr. G. W. Miller, Wisbech, showed a general collection of cut herbaceous plants, quite a number of seasonable flowers being included.

Mr. M. Pritchard, Christchurch, set up a very fine group of cut herbaceous flowers, with plants of *Spirea palmata* and the finer *Astilbes*, *Iris Kaempferi*, *Hemerocallis citrina Baronii* and *Sparaxis pulcherrima* were also noteworthy in the group. *Herbaceous Phloxes*, too, were excellently displayed.

Messrs. Stuart Low and Co., Enfield, staged an excellent lot of *Roses*, arranging *Rayon d'Or*, *Lyon*, *Sunburst*, *Lady Pirrie*, *Mrs. Alfred Tate*, *Pharisæer* and *Lady Hillington* in huge stands, which were most effective. A small yet resplendent group of good things.

Messrs. Carter Page and Co., London Wall, had a most extensive collection of *Violas* arranged in pans. Quite a large representative gathering.

Messrs. Camell and Sons, Swanley, showed *Roses* and *Pelargoniums* in great variety.

Mr. L. R. Russell, Richmond, had a fine lot of pans of *Veratrum depressa* in fruit, fronting a select lot of hardy flowers.

Mr. J. Douglas, Great Bookham, had a superb lot of *Carnations*, *Bookham White*, *Fragily* (both of which received awards of merit), *Jean Douglas* (rich scarlet), *Mrs. G. A. Reynolds* (bright orange with buff), *Elizabeth Shiffner*, *Linkman* (fancy) and *Agnes Sorrell* (crimson variegated with fine perfume) being among the best in a particularly choice and well-grown collection.

FRUIT.

Lady Wrenner, Luton Ho, Luton (gardener, Mr. A. W. Metcalf), showed boxes of *Strawberries* in splendid condition. *Given's Late Prolific* and *Waterloo* were the two varieties shown.

Messrs. James Veitch and Sons, Limited, Chelsea, received a gold medal for a splendid collection of fruit trees in pots, the collection comprising *Apples*, *Plums*, *Peaches* and *Nectarines* in the finest condition. Of *Peaches*, *Peregrine*, *Early Alfred*, *Dymond*, *Rivers'* *Early York*, *Crimson Galande* and *Royal George*; of *Nectarines*, *Goldoni*, *Pineapple*, *Early Rivers* and *Lord Napier*, and of *Plums*, *Early Transparent Gage*, *Jefferson's*, *Kirkle's*, *Denniston's Superb* and *Brandy Gage* were the best, while of *Apples*, *Lady Sudeley* and *James Grieve* were good.

ORCHIDS.

Four orchids were exhibited, Messrs. Sander and Sons, St. Albans, showing a collection of *Odontoidas*, *Vanda coelebs* (a very excellent variety), *Dendrobium Pearcei* and others.

Messrs. Charlesworth and Co., Hayward's Heath, had a small but choice lot of *Orchids*, such good things as *Cyclopis chlorochiloides*, *Laelio-Cattleya*, *Ceres*, *Angulata Chittum*, *Odontoglossum Othello* and *O. Mendis*.

A fine imported plant of *Aerides odoratum*, bearing six specimens of flowers, was shown by Mr. A. W. D. Oakes, Knockwood, Shortlands, Kent.

Messrs. Stuart Low and Co., Enfield, also contributed a small group.

SOUTHAMPTON SOCIETY'S SUMMER SHOW.

The summer show, held on July 15 and 16, which included the Southern Counties *Carnation* and *Sweet Pea* section, was a very beautiful one, notwithstanding the fact that a few classes were not very well filled. In many others, however, the competition was keen, good quality being a feature throughout. Mr. Ellwood's collections of vegetables, Mr. T. Hall's grand *Madresfield Court Grapes*, Messrs. Sutton and Son's superb exhibit of *Sweet Peas*, Mr. Dutton's *Carnations*, Messrs. W. H. Rogers and Son's old-world *Rose garden*, Messrs. Togood and Son's *Sweet Peas* and vegetables, Messrs. E. Lathams' alpine garden, and Messrs. Hillier and Son's herbaceous flowers, *Carnations* and *Water Lilies* were all outstanding features of the show. Mr. Fudge, the courteous secretary

had a plan of the tents, and all exhibits were neatly staged under his experienced supervision.

CARNATIONS.

In Class 1, for twelve vases of selfs, *Lancets* and yellow-ground *Picotees*, Mr. H. Mathias, Medstead, was first, staging *Linkman*, *Leslie*, *Mrs. R. Percy Smith*, *Margaret Thurston*, *Maud Allen* and a seedling in good condition. He secured nearly all the first prizes in Classes 2, 3, 6, 7, 8, 9 and 10 respectively for blooms shown in vases and on boards. Mr. J. J. Keen and Mr. H. M. Elford of Winton, Bourne-mouth, were also prominent prize-winners in these classes. The last named is a new exhibitor and an expert grower, and will, no doubt, make his mark in future in the show tents.

In the classes open to amateurs, Mr. J. A. Fort was the champion prize-winner. In many classes he did not have much competition, but his blooms were so good that first-prize cards were awarded.

In Class 30, for five vases of Tree or American *Carnations*, Mr. Usher, gardener to Sir Randolph Baker, Bart., was first, *Scarlet Glow*, *White Wonder* and *R. E. Felton* being very fine blooms.

In Class 31, Mr. Ellwood, gardener to W. H. Myers, Esq., was first for three distinct varieties of American *Tree Carnations*. Notable premier blooms were *Viola* in Class 9, shown by Mr. Keen; *Mrs. G. Marshall* in Class 8, and *R. Houlgrave* in Class 6.

SWEET PEAS.

In Class 40, for four distinct varieties, Mr. White, Eastleigh, was first.

Mr. Fisher was premier prize-winner in the class for six bunches in six varieties, the prizes being offered by Messrs. Sutton and Sons, Reading. Mr. Bealing, Bassett, and Mr. Clemson, Millford-on-Sea, were second and third respectively.

In the class for nine distinct varieties (prizes given by Messrs. Togood and Sons, Southampton), a second prize only was awarded, the other exhibits being disqualified, as they were not staged according to schedule.

For the best six distinct varieties, Mr. E. Bealing was first. The same exhibitor was placed first for eight bunches, the prizes being provided by Messrs. Webb and Sons. He again was successful in Class 46, for nine distinct varieties, winning the chief prize offered by Mr. Robert Sydenham, Tenby Street, Birmingham.

The *Sweet Peas* in the competitive classes occupied tables all round one large tent.

GROUPS AND POT PLANTS.

For a group of miscellaneous plants arranged for effect, Mr. C. Greenaway, gardener to Mr. C. H. Ashley, Bassett, was first. He made good use of *Francoa ramosa* and well-coloured *Crotons*. Mr. T. Hall, gardener to Ellen Lady Swaythling, was a very close second. His plants were well grown and choice, but rather closely arranged.

Mr. Hall had the best single specimen stove or greenhouse flowering plant—a well grown and flowered *Stephanotis*. Mr. Greenaway had the best single specimen foliage plant. Mr. C. Hoxey staged six giant and freely-flowered *Zonal Pelargoniums*, and was easily first. He had also the premier four *Ferns*, distinct, and six *Gloxinas* respectively; and Mr. Hall won with a grand lot of *Caladiums*, grown as one frequently saw them some twenty years ago.

Mr. Madingley, gardener to Admiral Sir J. Hopkins, won in the class for nine vases of hardy border flowers, distinct, Mr. W. Palmer, Andover, being a close second.

TABLE DECORATIONS.

These were very pretty, being low and lightly arranged. In one class Mrs. Bealing scored. *Carnations* or *Picotees* or both were to be used. In another class, *Orchids* only being excluded, Miss Mimmie Snellgrove won. *Sweet Peas* were used, and the effect was charming. *Epergnes*, *sprays* and other floral arrangements were equally beautiful.

FRUIT AND VEGETABLES.

Mr. T. Hall won in Class 69 for four dishes of fruit, staging *Madresfield Court Grapes*, *Sutton's Scarlet Melon*, *Lord Napier Nectarines* and *Dymond Peaches*. The same exhibitor won in the class for two bunches of black *Grapes*, again staging superb *Madresfield Court*. Mr. Ellwood was second with fine, even clusters of *Black Hamper*. Mr. Hall was again a winner in the class for one dish of *Peaches*. Mr. Usher had the best *Melon*.

In all the principal classes for collections of vegetables Mr. Ellwood won, staging grand produce in his well-known attractive style. The prizes were offered by Messrs. Togood and Sons, Messrs. James Carter and Co., Messrs. Sutton and Sons and Messrs. Webb and Sons respectively. Mr. Ellwood also had the best dish of *Tomatoes*.

NON-COMPETITIVE EXHIBITS.

Gold Medals.—A large gold medal to Messrs. Sutton and Sons for *Sweet Peas*; a gold medal to Messrs. W. H. Rogers and Son, Limited, for an old-world *Rose garden*; and a similar award to Messrs. E. Lathams, Limited, for an alpine garden and herbaceous flowers.

Silver-gilt Medals to Messrs. Togood and Sons for *Sweet Peas* and vegetables; Messrs. Hillier and Sons for herbaceous flowers, *Carnations* and *Water Lilies*; Mr. A. E. Dutton for *Tree Carnations*; and Mr. F. Longster for *Sweet Peas*.

Silver Medals to Mr. C. Fay for *Carnations*; and Mr. E. Wells for stove and greenhouse plants.

Awards of Merit to Messrs. Jarman and Co. for *Roses* and *Carnations*; and to Mr. F. Gullick for a lovely lot of *Violas*.

Mr. J. A. Medland had some charming vases of flowers finely fixed in his patent holders, and also some very *Strawberry* protectors.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Transplanting Bulbs in Grass.—Anyone desirous of transplanting or taking up spring-flowering bulbs in grass or under trees should not delay doing so, for although the tops are dormant and will remain so for a long time, the roots will soon commence to get active, and are then best left undisturbed.

Blackberries.—These provide a very useful crop during the early autumn, and the plants are greatly benefited by one or two good soakings of manure-water, especially during the time the fruits are setting. Green fly is sometimes troublesome, more particularly about the time the plants are in bloom, and if the insects are noticed the plants should be sprayed at once, or the fruit may be spoiled.

Lilium Brownii.—This is without doubt one of the most satisfactory of all garden Lilies. Recently a beautiful colony of this Lily, growing among peat-loving shrubs, was to be seen in the American Garden near the Palm House, Kew. It has been grown in the same bed for at least four years, and the fact that it continues to flourish and flower profusely is proof of its great value as a garden Lily.

Work Among Border Flowers.—To preserve the herbaceous border in a nice condition it should be gone over regularly, cutting down the plants that have bloomed, and thinning out and staking those that are coming into bloom, not forgetting to give those plants water and nourishment that most require it. The autumn-blooming plants are now making rapid growth, and such plants as Phloxes, Asters, Helianthus and Rudbeckias will be all the better for a little help in this direction.

The Iceland Poppy.—Few plants are more valuable for the garden or for use as cut flowers than the Iceland Poppy, *Papaver nudicaule*. The orange, yellow and white flowers blend well together, and are equally as effective when grouped in separate colours. Seeds sown now will produce plants to flower next spring, when they will be followed by the spring-sown ones. Poppy flowers will be found to last longer if the stalks are slightly burned at the tips before they are put into water.

A Useful Late-Flowering Broom.—The Mount Etna or Sicilian Broom, *Genista aetnensis*, is a valuable subject for the pleasure grounds and shrubbery borders, being one of the last members of the Broom family to flower. It is a particularly graceful shrub, 12 feet to 15 feet or more in height. Old specimens develop quite a thick, woody stem, with numerous main branches, from which hang the green, whip-like shoots, very freely dotted with small, yellow, pea-like blossoms. Seeds ripen freely in this country, forming a ready means of propagation. They may be scattered thinly where it is desired to grow them. The seedlings can be raised in a frame and the plants grown for

a couple of years in pots till large enough to safely establish in the woodland, pleasure grounds, or shrubbery borders. Single specimens are effective, but the Mount Etna Broom is seen at its best planted in informal groups of six to a dozen plants.

Rambler Rose Lady Godiva.—Although this sport from Dorothy Perkins was obtained by Messrs. Paul and Son five years ago, it is seldom that one finds it growing in gardens. Why this is so is difficult to understand, because it is unlike any other variety. The flowers are pale salmon pink, resembling closely in colour that charming Perpetual-flowering Carnation Mrs. H. Burnett. It is as vigorous and free-flowering as Dorothy Perkins, and deserves to be more widely known.

A Useful Dwarf Flowering Shrub.—It is difficult to understand why that charming little dwarf shrub *Spiraea japonica* Anthony Waterer is not more freely planted. For filling a large lawn bed or for grouping towards the front of the shrub border it is excellent, and has the merit of doing well in rather poor soil. If pruned hard back each winter or spring, as it should be, it only grows from 15 inches to 18 inches high, and in July and early August is covered with its large heads of deep rose red flowers.

Poplar Leaves Diseased.—At a recent meeting of the scientific committee of the Royal Horticultural Society, the Ven. Archdeacon Meredith sent leaves of a Poplar with large golden yellow areas upon them, occupying in some cases half the leaf surface, and due to *Ascomyces aureus*, a fungus nearly allied to the one producing leaf-curl in Peaches, &c. One or two of the leaves showed on their upper surfaces the silvery appearance characteristic of the attack of *Stereum purpureum* as seen in Plums.

Two Silver-Leaved Shrubs.—The genus *Eleagnus* comprises a number of ornamental shrubs, two of the best being *E. argentea* and *E. macrophylla*. The former is a native of North America, and is commonly known under the dainty name of Silver Berry. *E. macrophylla*, or *Fon Gum*, native of Japan and Formosa, has beautiful silver grey foliage, and is one of the best shrubs for planting in isolated beds on lawns where tall subjects are not desirable. The bright silver foliage of these shrubs stands out in pleasing contrast to the sombre appearance of coniferous evergreens.

Bed of Pale Lilac Shrubs.—A very charming bed at Kew just now is situated in front of the large Temperate House, a beautiful pale lilac effect being created by the use of *Ceanothus Ceres*. The large panicles of cloud-like blossoms are very freely produced on plants not more than 2 feet high. Judging from their appearance, these are pruned back almost to the ground-level each winter or spring, the flowers being produced on wood made this year. Near by is a bed, not quite so well filled, of the beautiful azure blue-flowered variety *Gloire de Plantières*, which has evidently been treated in a similar manner.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Zonal Pelargoniums Without Pots.—As I required a flower-pot many months ago of a particular size, I could only find one suitable in which a nice plant was then growing. However, I turned out the plant and simply placed it in a saucer, minus the pot. Occasionally water was poured into the saucer, but very often the ball of soil was quite dry and no water in the saucer. Finding, however, that the plant was thriving in the circumstances, I had it supplied with water as required, the latter being poured into the saucer. I am surprised to see how well this plant has grown and flowered in the circumstances. It was, when turned out, well established in a 6½-inch pot, and the ball of soil quickly absorbed the water from the saucer. Young roots stand out like bristles from the ball of soil. I refer to this plant as I firmly believe that we give too much water to Zonal Pelargoniums generally; hence so many yellow leaves.—SHAMROCK.

Lilium giganteum.—Upon reading the paragraph *re* *Lilium giganteum* in THE GARDEN of July 19, page 358, it occurred to me you might like to see the enclosed photograph, taken ten days ago, of *L. giganteum*, which has flowered here in my garden. The bulb was planted four years ago in a shady place; in fact, surrounded by shrubs, except to the north, as I find this Lily does far better in shade than in sun. There were nine spikes of bloom in all, bearing seventy-three blossoms between them. The tallest stem was 9 feet high with a head of thirteen blossoms; the next two, 8 feet 2 inches and 8 feet, with thirteen and eleven trumpets respectively. Then came one of 6 feet 9 inches, with the other five rather shorter and more hunched together. Lord Trevor, who is in the photograph, is about five feet eleven inches high. I have several more of these Lilies in the garden in sunny positions. None has more than one stem, and that not over 6 feet high.—ROSAMOND TREVOR, *Brynkinall, Chirk.*

Four Little-Known Roses.—There are four Roses not generally found in English catalogues which, I think, many would be glad to know. They are *Angèle d'Arnix*, a clear, warm pink of most distinct appearance, large size and upright growth. A good garden plant, and the bloom always opens well. *Reine Mère d'Italie* is certainly among the deepest of the yellow-hued Roses, and is very striking. Both the above are recent introductions of M. Bernaix, by whom they were kindly sent me. *Marquise de Ganay* is with me a tremendous bloomer, the flowers reminding one of Gustav Grunerwald, only of a better colour, being a pure light rose shade without any trace of magenta. What a splendid garden Rose is *Leuchtfleur*! It is a most brilliant thing and ever-blooming; in size and fulness it is equal to many a Hybrid Tea, especially in the early part of the season.—ERNEST BRVSON, *Yewtree Cottage, St. Briavels, Glos.*

About Garden Roses.—I was interested in reading an article headed "About Garden Roses" in your issue of July 19, page 359, signed by Edward H. Woodall, wherein was mentioned that the climbing wichuraiana hybrids *Gardenia* and *Alberic Barbier* were both equally good. I planted both these Roses only last November in different parts of my garden. Although only its first season, *Gardenia* has borne a profusion of blooms, and *Alberic Barbier* has supplied me with cut buds for the drawing-room and adorned the new archway up which it is planted in a manner quite unexpected for so young a plant. Both of these Roses are very highly to be praised on account

to suit it best. Now, while the other Roses are resting temporarily after their first blooming, *Lady Ilchester* is still to the fore, affording me flowers which, in the bud and half-developed stage, are very striking; but the flower opens too quickly to flat form, although even then the centre is well filled and the bloom of good lasting quality. It keeps its colour in sunshine and stands wet well. So far I have not found this Rose a very good autumnal variety. It is by no means the latest bloomer among the Hybrid Teas here. In growth, on dwarf stocks, the plants are inclined to be leggy; in other respects the growth is good. I find that this variety likes the knife no better than does J. B. Clark.—R. C. W. DIXON, *Southampton.*

Grouping Flowers for Colour.—Studies and experiments in this delightful aspect of gardening become more and more interesting and attractive. There is a fine old border plant, *Salvia Sclaria*, that seems to have gone out of use of late, but that is well worth restoring to favour. It throws up stems 4 feet high that bear large, loose, thyrse-shaped masses of bloom, each flowery top being 2 feet high and 15 inches wide. The upper lobes of the bloom are of a tender lilac colour, with a lighter lip and a warm white hanging pouch. The large mauve pink bracts combine with this to form a wonderful harmony of related colouring when seen close by, and a cloud of tender tinting when viewed from a little distance. Grouped with it is *Salvia virgata*, whose bloom is a strong purple that is made all the richer by the deep red-brown of the calyx. The two plants, in a group that covers several square yards, help each other in effect in a way one would hardly have thought possible. At the foot are pale pink *Snaydragons* and spreading masses of the quiet grey of *Artemisia stelleriana*; above, a little distance away, comes an arch of the pink bloom of *Rose Euphrosyne*.—G. JEKYLL.

A Late-Flowering Greenhouse Heath.—Comparatively few of the greenhouse Heaths flower at this season of the year, but of the limited number *Erica cerinthoides* is one. It is also one of the brightest-coloured members of the genus, and belongs to what is usually termed the hard-wooded Heaths, in contradistinction to such well-known kinds as *E. hyemalis*, *E. gracilis*, *E. spencertiana* and *E. willmoreana*, which are known as soft-wooded kinds. The species under notice forms a rather upright-growing plant, whose flowers, borne a dozen or so together in a terminal head, are tubular in shape, each about an inch long, and of a bright crimson-scarlet colour. As with many other members of the genus, the exterior of the blossoms is clothed with hairs more or less sticky. From its bright and distinct appearance a group of this Heath forms a pleasing feature in the greenhouse during the latter part of the summer, while it also sometimes extends into early autumn. Another species somewhat in the same way and flowering at much the same time is *E. verticillata*, whose flowers are in whorls on the upper parts of the main shoots.—H. P.

LILIUM GIGANTEUM IN LADY TREVOR'S GARDEN AT CHIRK.

of their foliage and the entire absence of smother fly or mildew. But in my opinion *Aviateur Blériot* surpasses either of these. It is about the same size, has flowered at the same time, is a lovely shade of orange yellow, highly perfumed, a vigorous grower, and has lovely foliage.—HONOR T. PITTS, *The Rectory, Loughborough.*

Rose Mary Countess of Ilchester.—I see that your correspondent Mr. E. H. Woodall, page 359, July 19 issue, invites accounts of the behaviour of this Rose in English gardens. Soon after this variety was issued I put it on both dwarf and standard stocks. The latter form, as in the case of most Hybrid Teas with me, seems

A Huge Rhododendron.—The enormous Rhododendron in the gardens of the Marquis of Ailsa at Culzean Castle, Ayrshire, has often attracted the notice of visitors, who can hardly, however, realise its great size. The tree is the ordinary *R. ponticum*, is no less than 21 feet high, and is, according to the measurements taken in 1912, 266 feet in circumference. It is understood to be one of, if not the largest specimen in the kingdom, and is in perfect health and showing no signs of decrepitude.—S. A.

The Future of the North of England Horticultural Society.—Allow me as a private individual to intimate to the gardening fraternity in general, and Northern horticulturists in particular, the opportunities that exist at present for development. The cards have been dealt and the call for trumps has been given. Has it been noticed, and will the response be forthcoming? There are two grand openings lying right in front of the North of England Horticultural Society, and it would appear that too much caution may prevent an advance through these open doors. (1) Without going into details, which are being thoroughly overhauled by legal and other interested persons, there is undoubtedly a crying need for a Northern School of Horticulture. The general idea is a Government Garden Institute, with the North of England Horticultural Society co-operating, with the object of training horticulturists capable of developing the economic resources of the soil at home or in the Colonies. (2) There is another clear call—the establishment of a North of England Horticultural Society's Rock Garden. Such a Mecca for lovers of rock gardens would be popular and useful. To me one thing is certain. When at a general meeting, to be called shortly, the music is faced, the tune will be played, for it is preposterous to think that the many enthusiasts who have sacrificed, gladly and willingly, their time and money will allow this Northern movement to end in failure. It is not as if cash was not forthcoming. All that is required is a strong lead and similar enthusiasm such as was displayed over the new Royal Horticultural Society's Hall and the Royal Horticultural Society's Gardens. Notwithstanding deaths and withdrawals, the North of England Horticultural Society still increases its membership. A seedling cannot be forced without harm being done. Also all progress comes through and by suffering. It is disappointing, too, to note that three Northern societies outside Yorkshire have accepted from the North of England Horticultural Society, which has tried to be true to name, free judging, costly medals, or other practical support, and then given nothing or practically nothing in return.—J. BERNARD HALL, *Rawdon, Leeds.*

FORTHCOMING EVENTS.

August 4.—Flower Shows at Bletchley, Atherstone, Epsom, Thornton Heath, Eye, Lichfield, Ashby-de-la-Zouch, Marlow, Sandway, Stourport (two days), Mansfield, Datchet and King's Lynn.

August 5.—Flower Shows at Leicester (two days), Navan and Aberdare. Scottish Horticultural Association's Meeting.

August 6.—Flower Shows at Cookhill and Clevedon.

August 7.—Flower Shows at Madresfield and Kenilworth. Perthshire Sweet Pea Show.

August 8.—Flower Show at Darwen (two days).

August 9.—National Carnation and Picotee Society's Show (Northern Section). Flower Show at Winshall.

ROCK AND WATER GARDEN.

ROCK GARDEN PLANTS FOR LATE SUMMER AND AUTUMN.

IT is a common complaint that the rock garden is dull and uninteresting in late summer and autumn, due to the fact that the vast majority of the plants we call alpine bloom early in the year. The complaint is doubtless well founded; but now that we have so many plants available from almost all parts of the world, it is possible to render the rock garden bright with at least a certain amount of bloom almost all the year.

Apart from the flowers which bloom naturally at the later season, it is possible by some consideration to plant some of the alpine in such positions that they will retain their beauty long after their sisters have ceased to flower. Many of these plants will bloom as well in shade or semi-shade as in sun, and, by keeping this in view, a fortnight or more may often be gained in the prolongation of the flowering period. Another point which deserves consideration is that there are some alpine which, under favourable conditions, will flower for a second time in autumn, though, it may be, more sparsely than in spring.

To ensure the full beauty of the rock garden in late autumn, it is highly desirable to include a number of the autumn-flowering Crocuses and Colchicums, as these are simply invaluable. In suitable, sunny, sheltered places the autumn Crocuses and Meadow Safrons look delightful. *Crocus speciosus*, its variety *Atchisonii*, pulchellus, iridiflorus, zonatus, asturicus, Salzmanni, longiflorus and nudiflorus are all comparatively cheap, and others will be found from the lists of the dealers for those who can afford more expensive plants. Of the Meadow Safrons the best are the varieties of *Colchicum speciosum*, including the grand white one, the double varieties of *C. autumnale*, *C. Bornmuelleri*, *C. giganteum* and *C. variegatum*. Then the dainty *Cyclamen neapolitanum* will give its rose or white flowers in September. *Leucojum autumnale*, a charming thing, flowers from July until frost in warm, sandy soil. The pretty little *Oxalis lobata* is another late-blooming plant, which, with *Saxifraga Fortunei*, will bloom even as late as October in warm, sheltered places.

Of other plants than those of bulbous or semi-bulbous character we find the *Tunicas* really indispensable. *T. Saxifraga* (rose) is best known, but *T. olympica* (white) and the double *T. Saxifraga flore pleno* are fine. Then *Silene Schaltia* is also most valuable, as it will bloom from July until frost.

A gem of the first water is *Androsace lanuginosa*, which, with its form *oculata*, will bloom all the summer through, and even until sharp frost intervenes. But for its toxy smell, *Phuopsis* or *Crucianella stylosa* would be more appreciated, but it blooms for months at a stretch. Some of the *Helianthemums* are grand flowers for our purpose, and the best are the double varieties of *H. amabile*. The red one, often known as Mrs. Earle, is hardly ever out of flower, and its yellow sport, *Jubilee*, and the one called *Old Gold* are equally floriferous.

Some consideration in planting in cool places will prolong the flowering of the dwarf *Campanulas* till the end of July in most seasons, and often later, and the writer will have some of these until well into August this season. The varieties of *C. carpatia* lend themselves well to this. *Ethio-*

nemas, beautiful in themselves, give a few valuable late bloomers, and among them I find *grandiflorum*, *cordifolium* and *cordatum* perhaps the best.

Dianthus, e.g., varieties of *plumarius*, most of the *Mule Binks*, and a few species, such as *deltoides*, *neglectus* and *gracilis*, are long flowerers. *Hypericum* give us a goodly variety, all with yellow flowers. *H. reptans*, *H. Coris*, *H. fragile* and *H. verticillatum* are among the best of the dwarf species. Though rather tall and coarse, *Alyssum sinuatum*, about a foot high, gives masses of yellow in late summer and autumn, and is useful for rough rockwork. *Jasione perennis*, blue, a foot high; *Globularia nana*, also blue, 3 inches or 4 inches; *Achillea tomentosa*, yellow, 6 inches; and *A. rupestris*, a white trailer, may all be named.

Erodiums afford us a useful variety, and any of these may be chosen with confidence. *Gypsophila prostrata* is fine, and *Polygonum vacinifolium* most valuable. *Oxalis corniculata* gives tiny golden stars; *Corydalis lutea*, though a little coarse, is good on a rough rockery. *Antirrhinum asarinum* will give blooms for some time, and *Heucheras* in suitable positions bloom well. *Arenaria montana* in the shadier, moister parts will afford some bloom; *Geranium lancastriense* and a few others will flower for a long stretch; and *Origanum hybridum* and *Tournefortii* and *Astragalus minor* and *gracilis* may be used.

The autumnal Heaths and the *Menziesias* are indispensable, and a full planting of these should be made, not forgetting *Erica hybrida* for still later bloom. With these and a few of the dwarfest annuals, such as *Ionopodium acule* and *Sedum caruleum*, the rock garden may be made delightful in autumn, if not so full of colour as in the earlier months of the year.

S. ARNOTT.

STERILISING SEEDS WITH HYDROGEN PEROXIDE.

THE current issue of the *New Bulletin* contains a most interesting article by Miss Ivy Massee on the sterilisation of seeds with a view to destroying spores of injurious fungi that might be present. A great many kinds of seeds have been experimented with, and we cannot do better than quote Miss Massee's summary: "The spores of fungi, also some kinds of bacteria, are as a rule killed by an hour's immersion in hydrogen peroxide; no spores experimented with germinated after similar treatment for two hours. In nearly every instance the germination of seeds immersed in hydrogen peroxide was retarded. Seeds immersed for four hours were on an average one to two days later in appearing above ground than untreated seeds of the same kind. Seeds treated for twenty-four hours were retarded from two to eight days, or in most instances were killed outright. The period of retardation is much less in seeds which germinate quickly than in the case of seeds whose germination is normally slow. After treated seeds have germinated growth is rapid, and in a short time the plants are equal in size and vigour to the plants from untreated seeds sown at the same time. In some cases the plants from treated seeds are distinctly larger than those from untreated seeds at the end of three weeks. For all practical purposes, soaking seed in hydrogen peroxide for three hours will kill all superficial fungus spores and the seed will not be injured. This method is to be recommended as a substitute for fumigation, which, as a rule, does not kill fungus spores, unless continued for such a time as to damage the seed."

TREES AND SHRUBS.

SHADE AND AIR IN THE GARDEN.

THE VALUE OF WEeping TREES.

SOME trees stand out prominently in the landscape by reason of their habit of growth, their distinct foliage and flowers, or possibly some other peculiarity. Among these the most distinct are, perhaps, those of weeping or pendulous growth. Very picturesque and charming effects can be made with them in large or small gardens, owing to the fact that they form a pleasing change from trees of normal growth. It is when planted as lawn specimens, with their graceful pendent branches just reaching to the grass, that the trees show off to the greatest advantage. Pendulous trees should stand out as specimens quite distinct from their neighbours. It is no use huddling them away in a shrubbery border with other trees and shrubs, as this at once destroys or, at any rate, partly robs them of their picturesque character. As a rule, trees of pendulous growth must be confined to the pleasure grounds and the immediate surroundings of the house. When planted in the park it is necessary to surround them with a fence as a protection against grazing cattle; this, it will be readily seen, detracts very much from their beauty.

Their Value for Shade.—One of the best and most valuable uses of a good weeping tree, particularly in a garden of moderate size, is as an arbour or retreat. While the pendulous branches hang down like a curtain and form an effective screen from the sun and surroundings to a large extent, the air beneath one of these weeping trees is never so close and oppressive as in the ordinary summer-house. These weeping trees readily respond to a little pruning and training with the idea of forming a shapely arbour.

Propagation is Important.

One of the most important items in the cultivation of weeping trees is their propagation. Grafting on the different types of the respective trees is the most satisfactory and only really feasible method. Seeds of some can be obtained, but the majority of the young plants would revert to the type. Layering and propagation by cuttings in some cases are possible, yet they are seldom, if ever, satisfactory, and in any case would take years to make a tree of any size. Much the quickest way to obtain specimen weeping trees is to graft them high up on stocks of the normal trees, 6 feet to 12 feet or even more in height.

Early Training.—The training of the leader of weeping trees in the early years of their growth is most important, always endeavouring to make them go upwards till they attain a good height. Too much stress cannot be laid upon this early training, for on it depends, to a very great extent, the future

of the tree. Some weeping trees, when grafted on a high stock, make fairly regular and symmetrical growth, e.g., the Elms and the Ash. On the other hand, some are most erratic in growth; take, as an example, the Weeping Mountain Ash, *Pyrus Aucuparia*. If this is not carefully staked and trained, the branches will be sprawling on the ground instead of hanging gracefully in streamers from an upright leader. We find it necessary to thin out the growths of the Weeping Holly and the Weeping Thorn fairly liberally about mid-summer in alternate years, or a little may be done about this time each year, otherwise the growths soon become a tangled and unbalanced mass of twigs and branches.

Elm, *Ulmus montana pendula* (illustrated on next page), and the Pendulous Feathered Elm, *Ulmus glabra pendula*. Both form large trees, the Weeping Scotch Elm in particular being in summer a luxurious mass of dark green leaves. There are several pendulous forms of the common Beech (illustrated). The best known is *Fagus sylvatica pendula*, which is often represented by large specimens covering a considerable area of ground. The trees exhibit great variation in the disposition of the branches. Some are fairly regular in outline, others throw out a stiff, vigorous branch on one side of the tree only, or perhaps at irregular intervals, giving the tree a rough, ragged outline. The leader of a young Weeping Beech will sometimes grow out almost or quite at right angles, and unless noticed in a young state, cannot be tied up straight, being too stiff. One of two alternatives may be taken, e.g., take up a fresh lead, cutting off the end of the old leader, or allow the tree to grow in its own erratic way. Two distinct forms which originated on the Continent are *bornyensis*, which has an erect stem and pendulous branches, and *remillyensis*, a Weeping Beech with pendent branches shaped more or less like an umbrella. There is a very pretty weeping variety of the Copper Beech boasting the long name of *Fagus sylvatica purpurea pendula*. There are also several pendulous forms of the Ash. The best known is *Fraxinus excelsior pendula* var. *Wentworthii*, which forms a tall, narrow tree, the leader being quite upright, with small branches disposed regularly round the trunk. *F. angustifolia pendula* is an elegant tree of tall, columnar outline.

Two Weeping Aspens should find a place in large gardens—*Populus tremula pendula* and *P. tremuloides pendula*. Two of the most graceful weeping trees are *Betula alba pendula* and *Youngii*. The former is tall and slender in growth, and *Youngii* broad and spreading. One of the best-known weeping trees among the general public is *Salix babylonica*, the Weeping Willow, a tree unequalled for effective planting by the lakeside, stream and swamp. The species in this case is a weeping tree. The main branches are more or less upright, with graceful, pendulous, leafy twigs. There are weeping varieties of the common Crab, the Siberian Crab and the Mountain Ash. In the *Prunus* family there are weeping forms of the Almond and Japanese Apricot. The Gean, a lovely tree when covered with white flowers in spring and suitable for small gardens, is catalogued as *Prunus Avium* var. *pendula*. The Rose-bud Cherry, *Prunus pendula*, from Japan, is a charming weeper, with dainty pink blossoms borne on slender twigs in April. The best of all the pendulous *Prunuses* for large gardens is the Weeping St. Lucie Cherry, *P. Mahaleb* var. *pendula*, which forms a glorious sight in spring when covered with blossoms. Another small-growing tree for

A WEeping BEECH OVERHANGING THE CARRIAGE DRIVE IN MR. W. A. BILNEY'S GARDEN AT WEYBRIDGE.

The Best Kinds.—The trees of drooping or pendent habit belong to widely different genera, and, as is only to be expected, differ considerably in height, habit, and other characteristics. One of, if not the tallest weeping tree in this country is at Elvaston Castle, the seat of the Earl of Harrington. The tree is 98 feet high, and one of the longest streamers hangs down to within 20 feet of the ground. An illustration of this famous tree appeared in *THE GARDEN* for December 23, 1905, page 400. Among specimens covering a large area of ground, the Weeping Beech is one of the most noteworthy. Two of the strongest-growing and most favoured pendulous trees for large gardens are the Weeping Scotch

tree. The main branches are more or less upright, with graceful, pendulous, leafy twigs. There are weeping varieties of the common Crab, the Siberian Crab and the Mountain Ash. In the *Prunus* family there are weeping forms of the Almond and Japanese Apricot. The Gean, a lovely tree when covered with white flowers in spring and suitable for small gardens, is catalogued as *Prunus Avium* var. *pendula*. The Rose-bud Cherry, *Prunus pendula*, from Japan, is a charming weeper, with dainty pink blossoms borne on slender twigs in April. The best of all the pendulous *Prunuses* for large gardens is the Weeping St. Lucie Cherry, *P. Mahaleb* var. *pendula*, which forms a glorious sight in spring when covered with blossoms. Another small-growing tree for

STEPPING STONES AND POOL IN THE NATURAL GARDEN AT MOUNTON.

ANOTHER FORM OF WEeping BEECH THAT MAKES A GOOD RETREAT ON A SUNNY DAY.

gardens of moderate size is the Weeping Hawthorn, a variety of *Crataegus Oxyacantha*.

Evergreen Kinds.—Among evergreens the most important tree with pendulous growths is the Weeping Holly, *Hex Aquifolium* var. *pendula*. There are also two very useful and attractive variegated Hollies, *argentea pendula*, known as Perry's Weeping, and *aurea pendula*, Waterer's Gold Weeping. The conifer family provides us with a number of exceedingly attractive trees. A few of the best and most distinct are the Weeping Lawson's Cypress, *Cupressus lawsoniana*, *C. pisifera* var. *filifera*, *C. nootkatensis* var. *pendula*, *Thuja occidentalis pendula*, *T. plicata pendula*, *Tsuga canadensis* var. *pendula*, and the Weeping Douglas Fir, *Pseudotsuga Douglasii*. The foregoing may appear a rather lengthy list, but it by no means exhausts the number of pendulous trees grown in the collection of trees and shrubs at Kew. Six of the best weeping trees for a garden of moderate size are the pendulous forms of the Green Holly, Perry's Holly, Hawthorn, common Ash, Young's Birch and Copper Beech. To these should be added to complete a list of twelve for extensive pleasure grounds Scotch or Wych Elm, Beech, Lawson's Cypress, St. Lucie Cherry, *Salix babylonica* and *Cupressus pisifera* var. *filifera*.
A. O.

THE FRUIT GARDEN.

THE LOGANBERRY AS A COMMERCIAL FRUIT.

THERE have been many new berry hybrids of the Bramble type introduced during the past fifteen years, all claiming some particular merit over others already in cultivation. Time and experience reveal the truth or otherwise of these claims. Among these are the Mahdi; the Hailshamberry, since proved to be an autumn Raspberry; the Lowberry, said to be excellent when grown under glass, but no good when grown out of doors—this is my experience of it; the King's Acre

Berry, of which I have had no experience; and the Newberry, which promises to be a success. It has been exhibited at the Royal Horticultural Society's meetings on several occasions. The branches are heavily laden with handsome fruit, which appears to be coreless—a considerable advantage.

Of the Loganberry there is no manner of doubt about its value and usefulness. It is now well known, much appreciated and sought after by the common people, and is now on sale at every greengrocer's shop, fetching here about 4d. to 6d. per pound. The gentleman first to find and practically

to point out the merits of the berry was Mr. Crump of Madresfield Court. Among Mr. Crump's varied activities in the county of Worcester, directing attention to the value of horticulture and more particularly fruit-growing for profit, both for farmers and cottagers, were, and are, the lectures he delivers for the Madresfield Agricultural Club. On one occasion his subject was the Loganberry; this is a good many years back. He had thoroughly tested this fruit, and was absolutely convinced of its great value, especially its commercial value for converting into jam and jellies, and therefore spoke of its merits with force born of conviction. In the audience was a gentleman farmer interested in the matter, and at question-time, to test the genuineness of Mr. Crump's conviction, asked him whether he would be prepared to share the loss with him if he planted an acre and it failed. Sportsmanlike, Mr. Crump said he would. Result, three parts of an acre planted; returns, £80 the second or third year after planting. The same gentleman grows tons of the fruit every year now, and has good reason to be satisfied with the results. Mr. Crump made a mistake in not stipulating for half the profits! This is an American fruit, and is a cross between a Raspberry and a Blackberry; and a very even cross it is, possessing, as the plant does, the vigorous growth of the Bramble and its heavy cropping qualities with, partly, the shape, size and flavour of the Raspberry, with a distinct briskness added of its own, which, however, disappears when the fruit is perfectly ripe, followed by a sweet flavour which I consider refreshing, not unlike the flavour of a dead ripe, well-grown Blackberry.

I have already drawn attention to the commercial value of its fruit. I wish also to as emphatically recommend its growth to the cottager. There is no other berry plant with which I am acquainted which will give him a better return for the little labour required in its growth. It seems to thrive well in almost any position, and is not particular as to soil. I have one plant growing and thriving well near the roots and in the shade

THE WEeping SCOTCH ELM, *ULMUS MONTANA PENDULA*, A HANDSOME TREE WITH DARK GREEN LEAVES.

of a Poplar tree, on cold, clay soil; but, of course, it would grow and bear fruit much better in the open quarter.

Culture and Propagation.—Like all the Bramble tribe, it will grow freely from seed, but being a hybrid plant, there is danger of its reverting to one or other of its parents under this mode of propagation. The best way is to grow it from layers. This is done by pegging the points of the long shoots to the ground at the end of July, burying the part pegged with soil to the depth of 3 inches or 4 inches. Tread the soil firmly down, leaving 6 inches or 7 inches of the extreme end of the shoot to grow into a young separate plant in the autumn after it has rooted and been cut away. Such rooted layers may then be planted in their permanent quarters 9 feet apart. If planted in rows, the rows should be 5 feet apart. The growth of the shoots in one year is phenomenal, often attaining a length of from 12 feet to 16 feet. Whether one trains the shoots to stakes or to a wire fence, these should be at least 6 feet high, and the shoots should be trained in a horizontal, not vertical, way. Another method of training to which the plant lends itself well is to cover arches, arbours, or screens to hide ugly corners of the garden in summer.

Pruning.—It should be pruned in the same way as the Raspberry, namely, by cutting away (down to the ground) all the shoots which have borne fruit, and that as soon as the fruit has been gathered. This will generally be at the end of July. One's attention must then be directed to the new canes, the growth of the current year, as it is these which will produce the fruit of the next year. They should be tied loosely to the stakes or whatever the old ones have been trained to. They will then be exposed to and have the advantage of all sunshine and air possible until the end of the autumn, when they can be secured to the stakes for winter and next summer. The branches must not be tied too closely together. They should be at least 2 inches apart. About ten inches of the tip end of the shoots should be cut back at the time of tying in in autumn or winter.

Winter and Summer Treatment.—In summer keep clear of weeds by hoeing or hand weeding. Gather the fruit closely every day as it ripens, or the birds will have it. Feed the trees when in fruit with manure-water if possible. It will pay one well to do so. In winter hoe the ground clear of weeds, and then fork the surface soil about two inches deep without disturbing the roots. Give a dressing, 3 inches deep, of good rotten manure to the surface of the soil over the roots as far as they extend. This will mean, when the plants are established, that all of the ground between the rows of plants will have to be manured. The best time to plant is early in November or at any time after until the end of February.

OWEN THOMAS, V.M.H.

A WATER GARDEN IN THE NATURAL STYLE.

[See *Special Supplement*.]

IT is a little difficult for us now to understand the fury of the battle between the formalists and the naturalists in garden matters which raged only twenty years ago. We now know that these are not opposing principles, but that each method should be used in its own sphere. The lay-out of a garden is right or wrong according as the limits of these two spheres have been thoroughly understood. Each case needs a practised eye to determine those

uncapable to be cast into a Level seldom make handsome gardens." If this were true, a more hopeless task than the making of a garden at Moun-ton could not have been imagined. Luckily, we now not only recognise the great beauty of such a site, but we have sound views as to how it should be treated. We are convinced that when hill and rock and rushing stream arrest attention by their pronun- cence, they should be accepted as the chief lines of a lay-out, that artifice should follow in their train and not oppose them, that man should, in such surroundings, leave the compass and the spirit-level and study Nature's own modes of expression. That has been the attempt at Mon-ton, and the results are to be judged by the

accompanying supplement. The site was a rocky limestone gorge, with sheer cliffs alternating with steep tree-clad bangers. At their foot a stream wound its way, sometimes surging round a bluff, at others running easily in the midst of a narrow meadow composed of the sandy soil brought there by the water's action of a million years. The general scheme of the grounds comprised a high and airy tableland, which could adequately accommodate on its comparatively flat surface a house and its terraces. The latter were to be separated by some broken rocky ground set with Heaths and low shrubs from the wooded slopes and precipitous sides of the limestone formation, which offered great scope for picturesque wild gardens. Pathways were engineered along the sides of these slopes, and they lead to the level bed of the stream and to what was a little meadow that lay between it and the lane. There was no hurry whatever to realise all this scheme. It was begun ten years ago, and the house and much of the formal lay-out on the upper flat still remain unaccomplished. The owner lives in the next parish, and this is the work of his leisure moments and for the employment of available labour in the winter months. The present purpose is not to describe the whole grounds, but only the water garden, made out of the stream itself, with the meadow on one side of it and the edge of the slope on the other. It was at first proposed to use the original

A BROAD EDGING OF THRIFT OR SEA PINK, A USEFUL PLANT FOR POOR SANDY SOIL.

limbs; but, roughly speaking, it may be laid down that, where Nature refuses to use her powers of attraction, the formalist can have sway, but that she should rule when- ever she has given herself the trouble to assert herself. This means that where natural forms are decided, varied and characteristic, the lay-out should give them full value and consideration, but that where the ground lacks distinction and feature, architectural and geometrical treatment may be resorted to. That is why gardeners of old, who were wedded to formalism and formalism alone, liked flat ground to work on. "The most graceful ground is an entire level," wrote John Rea in 1665; "hanging gardens

stream-bed and its banks for gardening purposes; but when, after some very heavy rains, much of the new planted stuff was swept away down stream to Severn Sea, and when at the close of a dry summer that which had not been swept away in the winter suffered severely from drought, owing to the stream becoming a mere rill, it was realised that serious alteration of the stream was necessary and that an artificial stream-bed where the water would be under command was essential.

It is not easy to get the ordinary gardener or labourer to understand natural forms. He can dig you a ditch or a canal, or even serpentine you a walk. But they will be set out with great

precision by means of pegs and a garden line. The making of the new stream-bed, therefore, needed close supervision and even the direct labour of the designer. Just before the original stream-bed took a decided turn from east to south he ordered a trench to be dug about twelve feet wide and five feet deep. This lay in the meadow, started within a few feet of the stream bank, and re-joined the original stream some eighty yards lower down. The top soil was wheeled well away, in order that it might not be buried, but be replaced as the top soil in the new arrangement. The under soil was tossed on either bank as unevenly as possible. All this preliminary work could be carried out by the labourers alone, but that done, the constant attention of the designer was essential. Uneven side bays were dug out on each side of the trench, while portions of the heaped soil were raked back into it. The accidental unevennesses produced by this process were used as a basis for establishing curves, levels and contours as closely as possible resembling those of Nature. At the bottom of the trench a small waterway was engineered, its windings being made reasonable by the introduction of realistic bluffs, and the differing widths being made convincing by the placing of barrier rocks. The same system makes all the zigzags and ups and downs of the pathways reasonable, the paths themselves being mostly laid with rough limestone paving procured from a stratum in a neighbouring quarry, which works out into slabs 2 inches or 3 inches thick and with fairly flat surfaces. The water was let in from the natural to the artificial stream-bed through a pipe in the bank, which can be closed, half opened or fully opened at will. The water is made to look, at its entry, as if it bubbled up amid great stones from a spring. It then dances rapidly down over stones and round corners until it reaches a wider and more level portion of the bed, where it lies placidly, and is crossed by the stepping-stones that form the foreground of the supplement. There are considerable areas of much-broken and often rocky ground encompassing both stream-beds, all of which is planted. Away from streams or paths flowering shrubs of some size are set. Lilacs, Japanese Guelder-Roses, Judas-trees, Weigelas, Deutzias and Philadelphuses represent the deciduous section, while for evergreens we find Choisyas and Savins. Tall perennials group with these or stretch out beyond them, such as Rudbeckia laciniata, Anemone japonica and Phloxes. Lower growths at first intermingle and then dominate as the path is approached. Lavender bushes, prostrate Junipers and Cotoneaster horizontalis are associated with Harebells, Foam-flower, dwarf Irises, Stonecrops and their like. The stream edge is set with water-loving plants. The great leaves of Saxifraga peltata and Rodgersia podophylla give horizontal lines, while New Zealand Flax and Siberian Irises soar aloft.

The whole race of Astilbes flourishes amazingly and reproduces itself by seed. This planted ground

has taken up half the width of what was meadow, but the other half is used as lawn. Next to the road there are a wall, a shrubbery border and a path. The open shed that served for the animals that pastured in the meadow is used as a tool-house, but its eaves are brought forward so as to afford a sheltered and covered seat, from which the water garden and the great cliff can be enjoyed by the eye. The lawn itself is no longer level like the meadow was, but presents the appearance of an unused stream-bed grassed over. The effect is very satisfactory, but the plan was adopted for purely practical reasons. The occasional torrential rains of this Welsh borderland bring down such masses of water that injurious floods occur. Their destructive action can only be obviated by getting rid of the water as quickly as possible. The sharp bend of the old stream tends to hold it back, and so a flood-gate is introduced at the head of the lawn, and when much pressure of water threatens

THE FLOWER GARDEN.

THE THRIFT AS AN EDGING.

TOO often in these days of new plants the merits of many old ones are overlooked, to the detriment of our gardens. One such plant is the common Thrift or Sea Pink, *Armeria vulgaris*, than which none is better for forming a neat and attractive edging to a pathway, particularly where the soil is sandy and thus unsuitable for many kinds of plant-life. The Thrift is a good-natured subject, and once planted will take care of itself, except that it may occasionally be necessary to curtail it somewhat when it encroaches too far on other domains. The illustration on page 386 depicts a broad edging of one of the varieties of the common Thrift, and shows how effective it is when in

A LITTLE-KNOWN SHRUBBY CALCEOLARIA, *C. INTEGRIFOLIA*, IN A SOUTH DEVON GARDEN. THE PLANTS ARE OVER FOUR FEET HIGH.

it is opened, and a great part of the water pours down the centre of the lawn, obviating all danger to the garden and to the low-lying gardener's cottage.

Despite its vagaries of water-level, a good deal of gardening, prudently ordained, takes place on the banks of the old stream. More delicate planting of water subjects takes place along the sides of the artificial stream. Here one of the greatest successes is *Primula rosea*. This Himalayan variety, while by no means so particular and miffy as others of the family, is not everywhere at home. Here it not only grows luxuriantly, but sows itself freely, and considerable stretches of damp ground on either side of the stepping-stones are studded by myriads of bright pink blooms in March.

H. AVRAY TIPPING.

flower. The blossoms last in good condition for at least six weeks, but even when they are absent the neat carpet of green foliage makes a useful and not unattractive edging. C.

A LITTLE-KNOWN CALCEOLARIA.

CALCEOLARIA INTEGRIFOLIA is apparently a rare plant, as when I sent flowers to Kew for naming I was told that they did not possess it, so I sent them some cuttings. It is extremely common in the gardens near the mouth of the River Dart, where it attains large proportions, and is one of the finest of summer-flowering shrubs. It is termed "shrub" because it is of woody growth, and a specimen here a few years ago was 6 feet in height and 7 feet in diameter. This would have considerably increased in size if it had not been cut back.

This *Calceolaria* has been growing at Kingswear for over forty years, but it is impossible to discover the source from which the plants originated. It has now spread from Kingswear over the greater part of the south-west of England, and has apparently been grown merely as a showy subject of easy culture, rather harder than the majority of shrubby *Veronicas* so much in evidence along the south-western coast-line. It is at its best in July, when it is a perfect sheet of gold, and it carries a fair amount of blossoms until well on into October. It is to be found in cottage and farmhouse gardens as well as in the ground surrounding the larger residences, and is invaluable for its masses of glowing colour. Some writers on the *Calceolaria* have stated that this species is useless for outdoor culture in England; but at Kingswear it is never harmed by the frost, which is rarely severe in that locality, as it is entirely sheltered from the north and east, while the steep slope immediately overlooks the salt water. Old bushes, however, have a way of becoming bare in their lower branches, when they are usually destroyed and their places filled with younger plants. In the severe weather of February, 1912, some plants on the borders of Dartmoor experienced 27° of frost, but though every leaf was browned, the shoots broke well again in the spring and now are fine plants, so that it is evidently far harder than has been imagined.

The plants in the border shown in the illustration on page 387 average over four feet in height, and, as will be seen, are well clothed with foliage to the ground-level. As these occupy a sheltered site, they will in all probability retain their lower leaves for a longer time than examples standing in a more exposed position. This *Calceolaria* has the advantage of being quite indifferent to soil. In rich and deep ground it forms exceptionally strong growth and flowers profusely; while in poor, stony and shallow soil, though making but little growth, it blossoms with equal freedom. At Kingswear a line of plants is growing in very shallow, stony soil immediately at the top of a dry wall, over which *Mesembryanthemums* hang in sheets, and backed at a distance of 18 inches by an old hedge of *Laurustinus*. This site, facing due south and entirely unshaded, is dust dry during the summer heat, owing to the combined action of the burning sun and the roots of the *Laurustinus*, but the plants, though making but little growth, never fail to bloom abundantly. WYNDHAM FITZHERBERT

A BEAUTIFUL CINQUEFOIL.

A CHARMING plant flowering just now is *Potentilla nepalensis*, known in a good many gardens as *P. willmottiana*. It somewhat resembles a *Geranium* in habit, the prostrate, spreading branches being freely bedecked with flowers of good size. It is a useful plant for either the border or the rock garden.

THE ROSE GARDEN.

SEASONABLE WORK AMONG ROSES.

NOW that our first show of Roses is past, it is well to do all we possibly can to help in the future displays; and much can be accomplished by cutting away any crowding and superfluous wood. The large trusses of spent blooms might often be cut off a little lower than is generally practised. In fact, the removal of stale flowers might be done rigorously enough to form a sort of summer pruning. We notice that our chief growths push from the terminal eyes of the shoots, and this often leaves several

NEW SEEDLING ROSE GORGEOUS, AWARDED A GOLD MEDAL AT THE NATIONAL ROSE SOCIETY'S PROVINCIAL SHOW. THE COLOUR IS SOFT PINK, SUFFUSED ORANGE.

dominant ones at and near their base. By more judicious cutting back we secure a lower and more bushy break of young growth, thus doing away with the chief cause of leggy and gaunt specimens. At the same time we should carefully avoid any tendency to crowding the centres of our plants. Much of this summer pruning might perhaps be more correctly described as thinning, for our main object is to stop badly-placed growth and overcrowding.

After flowering so unexpectedly well as our Roses have done this season, they will, naturally, need some support in the way of mulchings, if not already supplied in sufficient quantity. Now is the best time for sprinkling artificial manures over

the surface soil, and if it can be done previous to a shower, so much the better. A great deal of the feeding properties of our artificials is lost by air evaporation, and I strongly advise the hoe being used directly after sowing. This mixes the soil and manure, covering the bulk of the latter and so conserving its food, which will be assimilated all the sooner by rain or a free use of the water-can. If one intends to water, the majority of manures might well be used in the liquid, and will not only be quicker in their effects, but a considerable amount of waste will be avoided. I am a great believer in the hoe upon all suitable occasions, whether weeds are present or not; also in drawing some of the soil well up to all dwarfs. You cannot do wrong by a persistent use of the syringe still, for it is more often than

not the worst time for mildew when our second and third crops of young growths appear, and by consistent washing we prevent any serious settlement of this disease.

A great deal can be done in the way of summer propagation independent of the usual budding. Three parts ripened wood can be rooted freely upon a partially-shaded border of sandy loam. Younger lateral wood will be useful if rooted in boxes of sandy loam and leaf-soil, or in pots of similar compost, and kept quite close for a few weeks. But there are always interesting series of seasonable articles on propagating that by their clear illustrations go further in helping amateur readers than any mere words of my own can do. One point I have not yet noticed, however, is the easier propagation of our Moss, Damask and Cabbage Roses. These do not produce any great number of sucker-like roots suitable for parting from the parent plant, and may be made more plentiful if a few good shoots are layered into prepared soil around their base. A slight cut of the ordinary description when layering will help very much, and if left over until a second winter they will lift with really good balls of root. This is a better plan than attempting to root cuttings, and I advise it now, even if one's young plants are not to be removed. It helps in getting more vigorous

bushes, and we may take it as Nature's own lesson that all subjects having a tendency to run suckers out for fresh soil do better if encouraged or transplanted frequently. A. P.

A BEAUTIFUL NEW ROSE.

AMONG the many new seedling Roses that were shown at the National Rose Society's Provincial Show at Gloucester was one named *Gorgeous*, shown by Mr. Hugh Dickson of Belfast, and for which he received a gold medal. As will be seen from the accompanying illustration, this is a bold, full flower, and the colour is soft pink, suffused orange. It should prove a good Rose for both garden and exhibition purposes.

GARDENING FOR BEGINNERS.

THE PROPAGATION OF HEATHS BY CUTTINGS.

THE Heath or Erica family is a fairly large one, and consists of both hardy and greenhouse plants. They differ widely in their habit of growth, ranging in height from about nine inches to six feet or more. The various species

of the side shoots growing on the strong, vigorous young growths will be found to answer this description, and in August will be partially ripened. Thin, weak cuttings, though they will root, seldom grow away kindly and make good, sturdy plants, while many of the thicker, sappy growths would damp if inserted as cuttings. An inch to $1\frac{1}{2}$ inches, not longer, is a good average length for a Heath cutting. Many of the side shoots will be found about this length, and if removed carefully with a slight downward pull will come away from the main stem readily and have a nice heel at the base. Failing this, the shoots must be cut off just below the leaves at a joint. The bottom leaves must be carefully removed. A small, thin-pointed pair of scissors are useful for this purpose.

Planting the Cuttings.—The cuttings may be inserted moderately close together. A 5-inch pot (48 size), as shown in Fig. 1, will accommodate from thirty to three dozen cuttings. Place a layer of

with a rose on the watering-pot, and remove any damp or yellow leaves if present. The young cuttings will root in from two to three months, when it will be necessary to gradually admit air, this being done, to start with, by tilting the bell-glasses before removing them entirely. When growing freely the tips of the shoots should be removed, to induce the plants to make several shoots each and form nice little bushy plants by next May, as shown in Fig. 3. These young plants, if of a greenhouse variety, should be potted off singly in small pots, or, if belonging to the hardy section, planted out 4 inches apart on a prepared border outside, from where, in the following autumn, they can be transferred to the positions for flowering.

Hardy Heaths.—By growing a selection of a dozen hardy Heaths, flowers may be looked for throughout the year. In November, December and January *E. hybrida* is the most noteworthy. It is a dwarf spreading plant with pinkish red flowers. Following this closely we have *E. lusitanica* (odonodes), a tall-growing white Heath 4 feet to 6 feet or more in height; and the dwarf-growing *E. carnea*, reddish purple, and the white variety *alba*, all of which make a beautiful display for the first three months of the year. April and May sees the Mediterranean Heath, with reddish pink flowers, bushes 4 feet to 5 feet in height, covered with flowers, and the smaller dwarf variety *alba*. Then in summer and autumn we have *E. ciliaris*, *E. cinerea* and *E. Tetrahix*, three dwarf-growing Heaths with pinkish red blossoms, the last two with white varieties. In autumn we have the Cornish Heath, *E. vagans* and the white variety, flowering freely. Propagated in a similar way and requiring identical treatment are the numerous beautiful varieties of the Lang or Calluna vulgaris, and the Irish Heath, *Daboecia polifolia*, both of which flower from July to October. A. O.

1.—HEATH CUTTINGS PLANTED IN A POT FILLED WITH FINE PEAT AND SAND.

and varieties blossom at different seasons, no period of the year being without its flowering Heath. Many amateurs are under the impression that cuttings of both greenhouse and hardy Heaths are difficult to root. This, however, is quite a mistake; the cuttings root very easily, provided one or two very simple rules are followed. No season of the whole year is better than August and early September to insert the cuttings. At this time there are plenty of half-ripened young shoots on the plants, which make excellent cuttings.

Preparing the Pots.—As comparatively little depth of soil is necessary for Erica cuttings, the pots should be filled at least half full of broken crocks or other suitable material at hand for drainage. Over this place a layer of rough peat or moss to prevent the fine soil trickling down between the crocks and preventing the free passage of water. A suitable compost in which to root the cuttings consists of two-thirds peat, passed through a quarter-inch mesh sieve, and one-third sand. Fill up the remaining space in the pots with this material, press firmly, and leave the surface of the soil a quarter of an inch below the top of the pot to permit of a little fine sand being sprinkled over the surface and to allow space for watering. Water each pot well as soon as filled and leave it long enough to drain thoroughly previous to inserting the cuttings. The most serviceable sized pots to use are those known as 5-inch or 48 size. These are convenient to handle, and are just wide enough to take a 4-inch bell-glass, as shown in Fig. 2.

Taking the Cuttings.—The largest percentage of successes may be expected when cuttings of medium growth are inserted. In most instances

2.—COVERED WITH A BELL-GLASS TO ASSIST ROOTING.

fine sand over the surface of the pot, take a small pointed stick (dibber) in the right hand and a cutting in the left. Make a hole with the dibber, and as it is drawn out insert the cutting, and allow the sand to trickle in and fill up the hole. Press the cutting in firmly with the other (thick) end of the dibber. Water the cuttings with a fine rose on the spout of the watering-can, and allow the pot to drain for a few minutes before placing on the bell-glass, as shown in Fig. 2. Should a propagating-frame with just a little bottom-heat be available, the pots may be plunged in this. Failing this, place the pots under a hand-light in the shadiest part of the greenhouse or in a cold frame. Wherever they are placed, shade the cuttings from sunlight.

After-Treatment.—Every morning the bell-glasses should be removed and any moisture collected on the inside wiped off with a chamois leather or cloth. Water the cuttings when dry

3.—THE YOUNG PLANTS READY FOR POTTING OFF.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Double Arabis.—To ensure a good, even growth and plenty of bloom, propagation should be attended to now. Where the soil is of a light nature, cuttings put in now and kept sprayed will make quite nice plants by October or November, ready for removing to the beds; but where the natural soil of the garden is heavy, it is just as well to put three or four cuttings in a 3-inch pot, and these, if placed in a frame and kept shaded and sprayed, will soon prick up and make roots, when the lights may be removed and the plants treated quite hardily. Though a little more trouble, the results are infinitely better.

Violas sown in June should now be ready for transferring from the seed-boxes or beds to any vacant plot in the kitchen garden that may be suitable. Make the soil fine, and after transplanting keep them well supplied with water for a few days to ensure the plants growing away nicely.

Named Violas, owing to the drought, have in many instances gone out of bloom somewhat early. If the plants are cleaned over and partially cut back, it should ensure getting a crop of good, sturdy cuttings for propagating in September or early October.

Biennials and Perennials sown in June will in most instances be ready for transplanting into nursery beds. As in the case of the Violas, it is essential to make the soil very fine. This ensures plenty of fine roots, so that the young plants hit well, either in the autumn or spring, whenever they are planted in the quarters in which they are to bloom.

Early-Flowering Chrysanthemums in beds or borders should now be liberally supplied with manure-water, though if dry it is best applied after a preliminary watering with clear water. This should be given every few days, and the additional outlay in labour will be well repaid by the extra size and colour in the blooms.

Plants Under Glass.

Amaryllises that were flowered early will now be losing their foliage. Water should be gradually withheld, and the plants given full exposure to sun and air for a time before storing them away. Later batches that have not matured so much should be kept watered till all the foliage commences to turn yellow, when they should receive the treatment recommended above. Seedling plants must be kept growing until they attain flowering size, and those that are not already in pots large enough to carry them through the winter should have a shift at once, so that they may get a good hold of the soil before the short days. Keep a fair amount of heat and moisture in the pit or house in which they are being grown, but sufficient air must be given to ensure the foliage keeping strong and hard.

Hydrangeas.—The present is a good time for propagating the different varieties of *Hydrangea hortensis*. They will root quite readily in a cold frame. Up till last season I always rooted them singly in 3-inch pots, but I then found they rooted much quicker and made stronger plants if pricked into a bed of sand and leaf-soil, whence they were potted straight into their flowering pots (4½-inch).

The Kitchen Garden.

Leeks for late use may still be planted, selecting a piece of ground that is not likely to be wanted till quite late in the spring. As the plants may be a good size when planting out, they should be well watered for a time to prevent undue flagging. Early-planted Leeks must also be kept well watered if good specimens are desired, those for exhibition having a little more soil brought up to them about every fourteen days. Keep the paper collars, if used, just above the soil.

Runner Beans.—To keep up the supply this crop must not be stinted for water or manure, and when liquid manure is not available, a sprinkling of artificial once a week will do almost as well.

Cauliflower is another vegetable which will not thrive except under moist conditions, and as Peas become scarcer, this vegetable will be more in demand, so that the plants should be watered

at least twice a week during really dry and hot weather.

Tomatoes are doing pretty well this season, and where the plants were got out early, good crops are the result. Give water when necessary, and thin the foliage somewhat for the fruits to secure a full measure of sun. To get real deep-coloured fruits, gather early, just as they are turning from yellow to red, and store in light and air-tight boxes, when the colour will be equal to the very best fruits from under glass.

Fruits Under Glass.

Plums that are nearing the ripening stage must not be subjected to too much water overhead or at the root, or cracking may result, especially in the Gage varieties. A moderately dry and buoyant atmosphere, with just a suspicion of heat in the pipes on cold, damp nights, is the best for these fruits, and under such conditions they will keep for quite a long time.

Pears also require much the same treatment. The early varieties, such as Clapp's Favourite, Williams' Bon Chrétien and Marguerite Marillat, are fast ripening, and if not already placed by themselves away from the later ones, they should be shifted at once, as these latter will still take a fair amount of syringing and feeding.

Apples.—The early varieties also will be ripening, and such varieties as Lady Sudeley must not be kept about too long, or they are very apt to go soft and insipid to the taste, though they might look well. Later varieties that are swelling may receive a fair amount of syringing. This is essential, as colouring in Apples is, I think, much influenced by the amount of moisture in the atmosphere.

Hardy Fruit.

Raspberries.—The fruit being gathered, all old canes should be cut out at once, thinning the young ones also so that they receive a maximum amount of light and air. Should the canes not have made much growth, a good soaking of liquid manure will help them materially. Autumn-fruiting varieties may also be the better for a good feed, and if not already covered with fish-netting, it should be put on before any of the fruits ripen, or they will quickly be depleted by the birds.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Layering Carnations.—This work must now be completed without delay. Acting upon a hint thrown out in THE GARDEN a few years ago, I have proved that it is unnecessary to form a tongue in the layer, as is usually done. If an incision is made with a thin, sharp knife at the base of the joint and carried up through and out again just above the joint, other matters being properly attended to, 95 per cent. of the layers will root as well as by the older and more tedious method. Give the layers a watering when the operation is finished, and see that they are not allowed to become quite dry till roots are emitted.

Preparing Daffodil Quarters.—The Daffodil takes a very short period of rest, and where fresh plantations are to be made, the bulbs should be bought as soon as procurable. Meanwhile, the ground should be got ready.

Staking Gladioli.—These showy flowers will soon be throwing up their flower-spikes, and will require support. In the case of the commoner varieties, such as *branchleyensis*, *Hollandia* and *Childsii*, planted in lines, all that is needed is to drive in a few stout stakes, run a line of twine along, and then tie the individual flower-stems to the stretched line of twine. Fine named sorts, planted irregularly, should each have a Bamboo stake, care being taken not to pierce the bulb when inserting the stake in the soil.

The Rock Garden.

The Arenarias.—Although belonging to the "bumble creation" in the rock garden, the Arenarias should not be looked upon as a negligible quantity, for they have a beauty all their own. Especially is this the case with *A. balearica* when

seen clothing the surface of a damp stone. *A. cæspitosa*, *A. montana* and *A. tetraquetra* are all gems in their way, and should be included even in small collections.

The Shrubbery.

Summer Pruning.—By this date it will be found that Laurels and other strong-growing shrubs have developed a few over-vigorous shoots, to the detriment of the surrounding occupants. These should be cut away at once.

Preparations for Transplanting.—Where it is intended to transplant Hollies or other evergreens in the autumn, it will be well to run a sharp spade round the plants, so as to sever the roots at a distance of about two feet from the stem, giving the plants a good watering afterwards if the weather happens to be dry. By doing this now, the plants will receive less check when transplanted.

Plants Under Glass.

Training Climbers.—If this work is not regularly attended to, the young growth becomes entangled and the work is rendered doubly difficult. Thin out superfluous shoots, as it is only on well-ripened shoots that a full crop of flowers can be expected.

Crassula coccinea.—We grow quite a large batch of this old-fashioned succulent, and the bright, long-lasting trusses of waxy flowers are much admired. This is a good time to propagate plants. One cutting can be inserted in a 2½-inch pot, or three in a 3-inch pot. Use a compost of fibrous loam, sand and finely-pounded potsherds. Stand the pots in an airy frame and keep them rather dry after the first watering.

Sowing Mignonette.—A sowing of Mignonette should now be made for spring flowering. If wanted in 5-inch pots, Machel is the best variety, and it should be sown in the pots in which it is to flower. Sound loam, with about a third part of well-rotted cow-manure and some sand and old mortar, forms an excellent compost. Ram the soil fairly firm, scatter a few seeds equally over the surface, and cover lightly with some fine soil. Water prior to sowing, of course. Stand the pots on ashes in a shallow frame and cover with a sheet of newspaper till germination takes place. For large specimens the same size of pot may be used in the meantime, and some of the giant-flowered varieties should be sown for this purpose.

Fruits Under Glass.

Repotting Strawberries.—Plants must now be shifted into their fruiting pots, which should be 6 inches in diameter. See that they are clean, dry and efficiently drained, with a sprinkling of soot over the drainage. If the loam is rather heavy, about a third part of horse-manure should be used with some wood-ashes. If the loam is inclined to be light, well-decayed cow-manure should be used. Pot firmly, and stand on a bed of coal-ashes of at least 6 inches in depth to ensure perfect drainage.

The Hardy Fruit Garden.

Preparing Strawberry Quarters.—If they are expected to yield a full crop next season, Strawberries should be planted not later than the middle of this month. The ground should be deeply trenched; but, generally speaking, bastard trenching is to be preferred. Unless the ground is very rich, a layer of manure should be placed below each of the two spits. The distance at which the plants should be planted depends upon the vigour of the variety, but from 2 feet to 2½ feet between the rows and about fifteen inches between the plants in the rows will be found suitable.

The Vegetable Garden.

Winter Onions.—These should be sown by the middle of the month, and the ground should now be prepared for their reception. Onions require good cultivation. Trench the ground and work in a good quantity of organic manure. Nitrogenous matter can be given in the spring. For summer use White Lisbon is excellent, and for a keeping variety for autumn sowing Trebons is hard to beat. Sow in drills about a foot apart.

Lettuce.—A sowing should be made now for spring use. For a Cos, Bath is good, and for a Cabbage variety Sutton's Standwell can be highly recommended.

Celery will be benefited by a sprinkling of soot on a dewy morning. CHARLES COMFORT.
Broomfield Gardens, Davidson's Mains, Midlothian.

DAFFODIL SHOW NOTES.

A Beginning.—I know several people, among others a clergyman, a country squire, a doctor and a clergyman's son, who are sitting on a gate wondering if they will come down on the show side or not. There must be others there, too, whom I do not know. Let me assure them that they need not hesitate. Growing for show is a most pleasant occupation and Daffodil folk are pleasant people. If there is no local show near at hand, there are the two large ones at London and Birmingham, where every inducement is held out to the novice to make a start by the provision of classes where he will meet only exhibitors of the same standing as himself. The beginners' section has been a huge success at the "Midland." I would advise, if it is not too late, local show committees to get a copy of that schedule and frame theirs on similar lines. In my opinion, nearly all Daffodil societies might do a good deal more than they do in tempering the wind to the hesitating lamb, even if, money being none too plentiful, there has to be a curtailment of either prizes or classes in the open section. I should imagine everyone who is seriously thinking of joining the jolly band of exhibitors has already a collection of some sort, and that he or she—for I am always glad to think that the "shes" take the part they do in the local exhibitions—has a more or less embryonic knowledge of suitable varieties. They want to extend both. I venture to suggest that they should at once order from the Royal Horticultural Society, Vincent Square, Westminster, the new Daffodil Year Book at the cost of 1s. 6d. In it will be found a detailed list of all the winning flowers shown this spring at both London and Birmingham. A careful study of these two, side by side with a few trade catalogues of the present year, will be of the greatest help in making a selection of the varieties that are the best to buy, either as a beginning or as an addition.

Points to be Remembered.—First, early planting is vital for the production of prize blooms. I like making experiments, and this autumn I am going to plant a row of the same variety every week from now until the end of November and watch the result. I know, of course, that August-planted bulbs will give far better flowers than late November ones, but I am not sure of the date when palpable retrogression begins. Without this practical test I would fix the date about September 21, and say every show bulb must be in the ground by then at the very latest, and that from now onwards the earlier the better. Secondly, good cultivation tells most decidedly. I speak from my own personal experience, for I know the difference it has made to me in exhibiting at Birmingham. My recent successes there have been largely due to this. Of all the letters that I have from time to time received on matters pertaining to the show stage, none has given me more satisfaction than one I received about three years since from Mr. E. M. Crosfield congratulating me not on my *success*, but on my good and improved *cultivation*. The two words, from an exhibition point of view, are practically synonymous. Those who think they can attain the first without the second are Daffodil—not Middleton—moonlighters, expecting what they will never get. There was a good concrete example of this at Birmingham this spring. White Knight, which I consider the acme of refinement, even throwing in Mrs. Ernst H. Krelage and White Emperor, was staged more

than once in the single bloom class. The best—the one that had had the best cultivation—won. The other was not among the first five. What made so much difference? Someone may ask what do I mean by cultivation. Shortly, this: (1) Preparation of the soil by double digging, adding in the process some bone-meal. (2) Covering the beds with a light covering, such as fine leaf-mould or peat moss in case of very severe weather, unless the soil is very cold and damp naturally, when I would use some light covering, such as Heather. (3) Systematic hoeing or stirring the soil between the rows every two weeks from the time the leaves are an inch high until the blooms are nearly ready to expand, and then two or three times before the bulbs are lifted. (4) Being "easy" about dividing up. Over-division is a huge mistake; it weakens the plants so much. (5) Early planting.

Some Varieties Suggested.—I am going to confine myself to some of the moderate-priced ones that I do not think are so well known as they might be. I have put to each the approximate price.

Trumpets.—Cornelia (6d.). Hamlet (2s. 6d.), Leiden Jar (10s. 6d.), Cygnet (5s. 6d.), William

The Late Robert Sydenham.—I cannot close these notes without a reference to poor "Uncle Robert," whom everyone recognised as the life and soul of the Midland Daffodil Society. In the midst of a busy morning he was called away, never to take part again in his huge business and the many horticultural activities which must have been to him life itself. He was a keen man of business, and the two flowers to which he devoted especial attention in this connection were the Daffodil and the Sweet Pea. By his efforts these have been made more popular than otherwise they would have been, and as we who love Daffodils are the gamers, let me in your name say how grateful we are for what he has accomplished. It is as a populariser of the Daffodil (and the Sweet Pea) that his name will live in horticultural annals. JOSEPH JACOB.

A SWEET PEA CHAMPIONSHIP TROPHY.

THE Boundary Chemical Company of Liverpool are offering an International Sweet Pea Championship

THE CHAMPIONSHIP CHALLENGE TROPHY FOR SWEET PEAS TO BE COMPETED FOR AT THE CARLISLE SHOW ON THE 13TH AND 14TH INST.

Baylor Hartland (10s. 6d.), Treasure Trove (10s.), Loveliness (12s. 6d.), Mrs. G. H. Barr (21s.), Cleopatra (20s.), Rising Sun (21s.) and Diogenes (20s.).

Incomparables.—Northern Light (2s.), Ursula (2s.), Neptune (21s.), Steadfast (2s.), Warden (2s. 6d.), Noble (5s. 6d.) and Solfatare (2s. 6d.).

Barri.—Cossack (12s. 6d.), Ethelbert (3s.), The President (25s.), Charles (21s.), Charm (21s.), Occident (2s. 6d.), Red Chief (2s. 6d.), Orestes (9d.), Red Eve (10s.), Zenith (3s. 6d.), Cœur de Lion (2s. 6d.), Armorer (9d.) and Red Emperor (21s.).

Leedsii.—Norah Pearson (15s.), Kittiwake (15s.), Thora (21s.), Countess of Southesk (4s.), Evangeline (2s.), St. Olaf (12s. 6d.), White Countess (5s.) and Venus (21s.).

Poets.—Millie Price (2s. 6d.), Kingsley (20s.), Matthew Arnold (15s.), George Herbert (5s.), Acme (20s.) and Orange Ring (2s.).

Poetaz.—Admiration (3s.), Orient (1s.) and Sunset (1s.).

Challenge Trophy, to be competed for this season at the Carlisle and Cumberland Horticultural Society's Show at Carlisle on August 13 and 14. The chosen representatives are: England, Mr. A. E. Usher; Scotland, Mr. J. A. Grigor; Ireland, Mr. E. Cowdy; and Wales, Mr. T. Jones. The contest is the outcome of a wish expressed by Mr. Walter P. Wright that the champion growers should meet together each year at a given place for a friendly contest. The size of the trophy is 24 inches long by 12 inches high.

A Good Dwarf Shrub.—The Dyers' Greenwood (*Genista tinctoria*) is a very attractive dwarf shrub, and flowers during June and July. Growing some six inches to nine inches high, the spreading plants clothe the ground, and during June and July produce a profusion of yellow blossoms. There is no need to fill pockets in the rockery with rich soil for the Dyers' Greenwood; in fact, the plants flower more abundantly in poor, sandy soil.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

BOUNDARY WALL (Gigitts).—You would not harm the wall in any way by doing what you propose, and if there is an opportunity for the roots of the plants to descend later into the crevices of the wall, quite a number of the plants would thrive. As you desire to add to the height of the wall, you cannot do better than sow seeds of rather tall-growing Wallflowers, Intermediate Antirrhinums in variety, and red and white Valerian. Papaver nudicaule would be also good and pretty, both in effect and variety. The present is not a good time for the work, and late August to October would be much better. The Valerian in such circumstances often attains a height of 2 feet, and is also a good perennial. The Antirrhinums, too, are often perennial in such positions.

IRIS DISEASED (A. E. T.).—The Iris is affected by the Iris leaf blotch, and all diseased parts should be collected and burnt. The disease has been less prevalent this year because of the extreme dryness. A wet season always encourages the spread of such things. By dusting the soil of the Iris bed with lime, the ground spores of the fungus might be kept in check. In a year like 1912, however, you might try syringing with sulphide of potassium, 2oz. to a gallon of water, with soft soap freely added; or you might, when the plants are moist, dust them with dry Bordeaux powder, soil and all. The dusting should take place in April or May to act as a preventive measure, and probably no other will be needed. To wait till the plants are overwhelmed by disease is wrong. Isolate the weakly plant of *I. orientalis*, or, better still, dig it up and burn it. The best time to replant the Hellebore, when it should also be divided up quite freely, is August.

TREES AND SHRUBS.

RHODODENDRONS (T. W. H.).—You do not say whether your Himalayan Rhododendrons are in pots or planted in borders. If in the former, expose the plants from now to the end of the year to plenty of sunshine, and do not keep them too wet at the roots. This treatment will conduce to the well ripening of the wood and to the formation of flower-buds. If they are planted in a border, you cannot do much to hasten their time of flowering; but no doubt they will flower in due time and will repay you for waiting so long. Seedling Rhododendrons do not flower so soon as grafted ones.

THE GREENHOUSE.

SECONDARY BLOOMS ON PELARGONIUMS (M. L.).—Some varieties of Zonal Pelargoniums are far more likely to produce secondary heads of blossom than others. You do not say whether the trouble is limited to one kind, or if all the varieties are similarly affected. Plants whose roots are in a poor condition, and are, consequently, growing weakly, are more prone to this behaviour than the more robust ones. Plenty of air, good healthy roots and a reasonable quantity of water consistent with effective drainage are the more effectual methods of keeping this in check.

FUCHSIAS LOSING THEIR LEAVES (R. J. C.).—As Fuchsia plants are, generally speaking, of such easy culture, it is difficult to assign with confidence any reason for yours behaving in the way they have done. In the first place, you say that they did not lose their old leaves in the spring, which would suggest that you kept them freely watered throughout the winter. This might be answerable for some of the trouble, as the plants naturally would not start away with the same vigour as if they had passed the winter in a fairly dry and dormant state. Even then they should not have behaved so badly as yours have done. Another question is whether any deleterious matter came by any chance to be mixed with the potting compost. You do not say whether you have turned out two or three of the plants, in order to examine the state of the roots. If a fair amount of fresh, healthy roots can be seen taking possession of the new soil, your plants will no doubt now recover and flower well towards the end of the summer. If no healthy roots are to be seen,

we advise you to repot in some fresh compost. In any case, do not stand the plants in full sun, but in a partially-shaded spot, and spray them over with the syringe two or three times a day, as atmospheric moisture is very beneficial to Fuchsias in general.

HYDRANGEA NOT FLOWERING WELL (L. C.).—The specimen of Hydrangea sent is not the common Hydrangea (*H. Hortensia*), but the variety Lindleyi. This differs markedly from the common kind, inasmuch as it is of more slender growth and the flower-heads much smaller. Another important item is that in this variety the large sterile blooms, which form the showiest portion of a cluster of Hydrangea flowers, are limited to a few scattered round the outside of the cluster, and not, as in the common kind, forming one closely-packed head. The sprays sent have certainly a poor and unhappy look, but there is no error of culture answerable for the paucity of the large, sterile blooms, this feature being simply characteristic of the particular variety. We should advise you to obtain some good, young, vigorous plants from a reliable source, and if they are liberally treated, your trouble will, we think, be at an end. One thing worthy of note is that the variety Lindleyi is harder than the common Hydrangea, so that if you plant out yours, they will as flowering shrubs probably give you far more satisfaction than they have done in pots.

FRUIT GARDEN.

TARRED FELT AND APPLES (T. W. H.).—Lime is the most effective deodoriser we have. We are sorry it was not powerful enough to destroy the smell of the tar. A thin layer of short lawn grass would be useful in helping to prevent the too rapid evaporation of moisture from the soil in which your Apple trees are growing. It must not be applied too thickly, or it will beat and become mildewed and nasty, and prevent air and rain from penetrating into the soil.

RASPBERRIES DISEASED (H. T.).—The white patches on the stems of the Raspberries sent are symptomatic of the disease due to *Hendersonia rubi*; but you do not send the lower part of the stem, where the disease is probably worse, so that we cannot say exactly whether this fungus or some other is at work. For spraying, Bordeaux mixture, at the strength usual for spraying Potatoes, should be used, but not within three weeks of picking the fruit. The old canes should be cut out completely as soon as possible, and the young ones sprayed with the Bordeaux mixture or with potassium sulphide, 1oz. to three gallons of water.

PEACH LEAVES DAMAGED (J. H.).—The leaves are thin, with no substance in them, showing that the trees are not in robust health, and therefore liable to an attack of disease when subjected to such strong bursts of sunshine as we have had lately. The damage has been caused by an attack of what is termed shot-hole fungus. The best remedy to apply is to scatter sulphur thickly over and under the leaves, leaving it on for a couple of days, shading the trees in the meanwhile, and afterwards syringing off the sulphur. Give the trees abundance of air night and day, syringing them morning and evening to encourage new and healthy growth.

MISCELLANEOUS.

CLASS AND ENTRY BOOKS (W. J. P.).—The most serviceable books are those prepared by the secretary. A book with quarto pages, ruled faint, should be used, and a line may be drawn down the left side of the page 1 inch from the edge. On the top line put the class number and its contents. To the left of the marginal line put the exhibitors' numbers, and to the right the exhibitors' names, but not their addresses. Thus we may have a headline as follows: "Class 24, four dishes hardy fruits, distinct kinds." Beneath we may read: "1, Chas. Jones; 5, Harry Wright; 6, W. J. Farr; 10, Tom Browne; 22, R. B. Pearce; 24, J. Adams." One sees at a glance who is in the class, and when the judges have made their awards, the secretary should go round the show and inscribe the awards in this book, which is called the Class Book. A second similar book, thumb-indexed, is called the Entry Book. The entries are placed in alphabetical order, and each is entered thus: Entry No. 24, J. Adams, complete address, and beneath, arranged in a column, the number of classes in which he is competing. And thus one proceeds for each exhibitor. When the judges' decisions have been entered in the Class Book, transfer to the Entry Book, and it will be seen at a glance to how much prize-money each exhibitor is entitled.

NAMES OF PLANTS.—*L. S. B.*—Rose Mme. Alfred Carrière.—*Miss K. Denison.*—The Carnation is John Pope, a good old border sort, but very much improved on now.—*E. D.*—The Roses are: 2, Daniel Laconbe; 3, Mme. Jean Dupuy; 4, Gloire de Exposition de Bruxelles.—*Hampshire R.*—Senecio Jacobaea. It is a perennial, and reproduces itself from seed. The best way to get rid of it is to dig it up.—*Ignoramus.*—1, The Campanula is a seedling form of *C. rotundifolia*; 2, the Viola was quite withered up when it reached us. Send again packed in damp moss.—*W. G.*—1, *Dianthus deltoides albus*; 2, *D. plumarius* variety; 3, *D. Waldsteinii*; 4, *D. superbus*; 5, *Sedum obtusatum*; 6, *S. spatulifolium.*—*G. R., Somerset.*—*Acanthus mollis.*—*A. B. C.*—2, *Spiraea canescens*; 3, *Verbascum olivaceum*; 4, *Salisburia adiantifolia* (*Ginkgo biloba*), Maiden-hair Tree; 5, *Sedum roseum.*—*G. Britnell.*—1, *Enphrasia officinalis*; 2, *Spiraea Ulmaria*; 3, *Teucrium Scordonia*; 4, *Hypericum pulchrum*; 5, *Galium verum*; 6, *Calamintha Clinopodium*; 7, *Senecio Jacobaea*; 8, *Baetylis glomerata variegata*; 9, *Centaurea nigra*; 10, *Potentilla Tormentilla*.

SOCIETIES.

NATIONAL CARNATION AND PICOTEE SOCIETY (SOUTHERN SECTION).

The exhibition of this society, held in the Royal Horticultural Hall on July 18, was a most interesting display for lovers of the border Carnation and Picotee. There was a good number of entries, and the flowers shown were of exceptionally good quality, there being a fair attendance during the afternoon.

DIVISION I.—FLOWERS SHOWN ON CARDS.

The first prize for twelve blooms, bizarres and flakes, dissimilar varieties, was secured by Mr. James Douglas, Edenside, Great Bookham, Surrey, who had a most effective set, consisting of Recorder, Master Fred, Sarah Payne, Supreme, Gordon Lewis, J. S. Hedderley, George Melville, R. Houlgrave (the premier scarlet bizarre), Kiobe, Torchlight, Meteor and Tonatit, Messrs. C. Bick, A. R. Brown, Limited, and H. Mathias followed in order of merit.

For twelve selfs, dissimilar, Mr. J. Douglas again led, the winning varieties being Bookham White, May Day, Miss Willmott, Bookham Yellow, Cardinal, Mrs. George Marshall, Maud Allen, Mrs. Guy Scbright, Basuto, Miss Shiffner, Robert Bruce and Ruby. Mr. H. Mathias followed with a nice clean set as second, Messrs. A. R. Brown, Limited, third, and Mr. Charles Bick fourth.

Mr. Charles Bick secured leading honours for twelve fancies, dissimilar, Mr. H. Mathias second, Messrs. A. R. Brown third, and Mr. J. Douglas fourth, the latter winning a premier with Linkman.

For twelve Picotee blooms, white ground, dissimilar, Mr. J. Douglas took first, Mr. C. Bick second and premier with Merlita, and Mr. H. Mathias third.

For twelve Picotee blooms, yellow ground, dissimilar, Mr. Charles Bick secured first and premier with Her Majesty, Mr. James Douglas second, and Mr. H. Mathias third.

DIVISION I.—FLOWERS SHOWN AS GROWN.

In the class for four varieties of Carnation blooms, selfs, to be shown in vases, three blooms of each variety, with Carnation foliage, Mr. J. Douglas secured first, Mr. C. Bick second, Mr. S. J. Payne third, and Mr. H. Lakeman fourth.

For a similar number of fancies, other than white ground, Mr. J. Douglas again led. Mr. H. Mathias was second, Mr. C. Bick third, and Messrs. A. R. Brown fourth.

In the class for white-ground fancies, Mr. J. Douglas was first, Mr. C. Bick second, and Mr. S. J. Payne third.

For four varieties of Picotee blooms, yellow ground, three blooms of each variety, Mr. J. Douglas came first, Mr. C. Bick second, Mr. S. J. Payne third, and Mr. H. Lakeman fourth.

Some very interesting stands were provided in the class for nine distinct varieties, including selfs, fancies and yellow-ground Picotees, in separate vases, three blooms of each variety. Mr. J. Douglas coming first, Mr. H. Mathias second, Mr. H. Lakeman third, and Mr. C. Bick fourth. It should be noted that the trade growers can only show in Division I.

DIVISION II.—FLOWERS SHOWN ON CARDS.

For six Carnation blooms, bizarres and flakes, dissimilar, Mr. H. R. Taylor, Chess, secured the leading award, Mr. J. Fairlie, Acton, coming second and securing a premier with Gordon Lewis.

In the class for six Carnation blooms, selfs, Mr. H. R. Taylor was again first, Mr. C. A. Linzee, Aylesford, taking second and premier with Mrs. George Marshall.

For six Carnation blooms, fancies, dissimilar, Mr. H. R. Taylor again led, Mr. J. A. Font, Winchester, coming second.

In the class for six Picotee blooms, white ground, dissimilar, Mr. J. J. Keen obtained first place, and Mr. H. R. Taylor second and a premier with the variety John Smith. For six yellow-ground Picotee blooms, dissimilar, Mr. H. R. Taylor was awarded first and a premier for Eclipse.

DIVISION II.—FLOWERS SHOWN AS GROWN.

For three blooms, one variety, pink or rose selfs, Mr. W. H. Parton obtained first, Miss E. Shiffner second, Mr. R. Morton third, and Mr. J. A. Font fourth.

For three blooms, one variety, white selfs, Mr. J. Fairlie secured first, Mr. R. Morton second, and Mr. E. J. Price third.

For three blooms, dark red or maroon selfs, Mr. C. A. Linzee secured first, Mr. W. H. Parton second, and Mr. F. Pitcher, Maidenhead, third.

Miss Shiffner secured the leading position for three blooms of yellow selfs, and Mr. H. R. Taylor came second. Mr. R. Morton, Woodside Park, N., occupied the premier place with three red or scarlet selfs, followed by Miss Shiffner.

The following exhibitors secured first prizes for the respective classes: Mr. R. Morton for three yellow-ground Picotees; Mr. H. W. Frostick for three buff or terracotta selfs; Mr. J. Fairlie for three selfs; Mr. J. A. Font for three yellow or buff ground fancies; and Mr. H. W. Frostick for three fancies other than yellow, buff, or white ground.

OPEN TO AMATEURS ONLY.

The Martin Smith Memorial Challenge Cup class was strongly contested, Mr. R. Morton, Woodside Park, N., again winning the cup with a splendid set of blooms. The varieties shown were Donald McDonald, Cardinal, Santa Clara, Basuto, John Ruskin, Skirmisher, Lord Steyne, Linkman, Onward, Bookham White, Margaret Lennox and Miss Willmott. Mr. W. H. Parton, Moseley, came second, and Mr. J. Fairlie, Acton, third.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Removing Seed-Pods from Plants.—To obtain as much bloom as possible from plants it is very important to remove all seed-pods as soon as they appear. By doing so the majority of plants, particularly annuals, will continue to flower for a very much longer period than they would if allowed to develop their seeds.

Dividing Pæonias.—As soon as the foliage of the plants is getting dry, it will be a suitable time to divide them where necessary. By doing so now the succulent roots will suffer less than if disturbed in the autumn or spring. It is advisable to select dull weather for the operation, if possible, although this is not absolutely necessary, but an occasional watering will be found very beneficial.

Honour for Viscountess Wolsley.—The Honorary Freedom of the Gardeners' Company was presented to Viscountess Wolsley on Monday of last week as an appreciation of her work in the interests of gardening. The presentation was made by the Lord Mayor of London. At the dinner held afterwards, the Master of the Gardeners' Company stated that Lady Wolsley had created a new profession for women.

An Interesting Bellflower.—One of the most interesting of the Campanulas or Bellflowers just now is *C. lanata*, a plant that does not appear to be at all well known. The lower shoots press closely up to the rockwork against which it is planted, while the main shoot grows erect. The flowers are large, creamy white in colour, and are now open. We noticed some particularly good plants in the rock garden at Kew a few days ago.

Fruit and Potato Crops in the Bordeaux District.—We are informed by the Board of Agriculture that a report received from the Bordeaux Consular District states that Plums are not likely to be very plentiful, the fruits having dropped badly during stoning. Marbat Walnuts are expected to give a moderate crop, and the Carnes variety a medium crop, but the well-known Grenoble Walnut is likely to be short. Potatoes are likely to yield well, as, up to the present, disease has not appeared.

A Pretty New Zealand Shrub.—In *Plagianthus Lyallii* we possess a valuable deciduous flowering shrub belonging to the Mallow family. Planted in the open border, it forms a large bush 7 feet to 8 feet or more in height. The flowers are freely produced in clusters in the axils of the leaves. They are 1½ inches or more across, pure white and slightly cup-shaped. The flowering season is July. Coming from New Zealand, those who are acquainted with the character of the flora know that sometimes, during very severe winters, trees and shrubs suffer considerable damage. For this reason, in the colder parts of the country, *Plagianthus Lyallii* is planted against a sunny south wall. At Kew a few years ago a bush growing in the open was cut to the

ground; the following year, however, vigorous young shoots pushed up from the base, and it is now a large, spreading bush 8 feet in height and flowering profusely. Layering forms the readiest means of increase.

The Irish Heath.—In the Heath garden just now this plant, *Daboecia polifolia*, is one of the most conspicuous features, its erect shoots, clothed with dancing, balloon-shaped flowers, attracting much attention. At Kew they have it grouped in good-sized masses, together with the white-flowered variety appropriately named *alba*. Another very charming variety at Kew is named *D. p. erecta atropurpurea*. This is rather more erect than the type, and has large flowers of rich rosy purple hue. These Irish Heaths are amenable to the same treatment as the hardy Heaths proper.

Transplanting the Madonna Lily.—Anyone desirous of transplanting the beautiful Madonna Lily, *Lilium candidum*, will find the present time most suitable. Seldom are the plants seen to better advantage than in a cottage garden where they are left undisturbed for years, which goes to prove that they should only be taken up when absolutely necessary through overcrowding. When the largest bulbs should be replanted and the smaller ones grown for a year or two in the nursery. If the plants are suffering from the disease which often attacks them, the bulbs ought to be freely dusted with sulphur before they are replanted.

Nemesias for Spring Flowering.—These lovely South African flowers are much appreciated in the conservatory or greenhouse in springtime. The plants are easily grown in pots from seeds sown in August. *Nemesia strumosa nana compacta* and *N. s. Suttonii*, both producing mixed colours, are suitable varieties for pot culture. If the seeds are sown in boxes or pans, the resultant seedlings must be transplanted in pots while quite small, five in a 6½-inch pot being sufficient; or they may be sown in the larger pots and surplus plants drawn out, the after-treatment being similar to that given to pot Mignonette.

A Perpetual-flowering Veronica.—Because occasionally, when planted in exposed positions, the shrubby New Zealand Veronicas suffer during severe frosts, many horticulturists neglect them. Suitable positions can be found for them in most gardens—a shrubby border with a south or west exposure, or similar aspects sheltered by a wall or fence. Even if the plants are occasionally damaged or killed outright when growing in the open, they can soon be replaced by young plants grown from cuttings, which are as easy to root as Fuchsias. One variety in particular, named Autumn Beauty, may be truly described as a perpetual-flowering Veronica, for it is seldom, if ever, without a few flowers, while during summer and autumn the bushes are laden with blossoms. Growing and flowering freely from 12 inches in height upwards, the plants are covered with small, dense racemes of rich purple flowers about two inches in length.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Are Ten-Week Stocks Dying Out?—In "Notes of the Week," issue July 26, the reference to these Stocks is very timely. Everything should be done to encourage cultivators to grow them still more than they have been in the past. Undoubtedly the reasons advanced in the note referred to are the true ones, as plants of the intermediate section do grow larger and branch more freely. The coarser and more branching specimens of the Ten-week section generally bear single flowers, whereas the dwarfier ones bear double flowers and usually form one very handsome spike. The time needed in which to grow good Ten-week Stocks is not unduly long. Perhaps committees of horticultural societies will note the references to this subject and in future provide two classes, one for Ten-week Stocks only.—G. G.

Rose Gustave Regis as a Large Bush.—The enclosed photograph of Rose Gustave Regis growing in a suburban garden may be of interest to some of your readers. In my opinion it is the best of the old garden Roses for suburban districts, in spite of the fact that it does not flower much in the autumn. The plant illustrated stands over five feet high, and a week after the photograph was taken scarcely a leaf could be seen for flowers. In the bud stage the colour is soft nankeen yellow, the flowers opening to creamy white. The buds, which are long and of exquisite shape, are excellent for button-holes. I do not understand why more of such Roses as Grüss an Teplitz, Florence Haswell Veitch and J. B. Clark are not grown as large, free bushes.—A. B. ESSEX.

Pruning Rose La France.—I quite agree with the note on this subject on page 371, issue July 26, above the well-known initials "G. G." Several years ago a number of correspondents wrote calling attention to the merits of unpruned Rose bushes. At that time a note from my pen described a specimen of Rose La France which had received no pruning for years and carried a large quantity of splendid flowers. La France is often disappointing when hard pruned in spring. Where this is so I would advise the practice of thinning out the weak shoots now, and cutting off the soft tips in March. Many other Roses might be treated in this way with advantage. There is a row of Rose Perle d'Or not far from where I am writing, the individual bushes of which are from 4 feet to 5 feet in height, and they have been covered with bloom and present a fine effect in the garden. These bushes are allowed to grow at will, the only pruning they receive being the removal of dead wood and dead flowers. Where space permits

(and especially in the wild garden) unpruned or lightly-pruned Roses should be given a trial. Many of the ramblers would be more satisfactory with less pruning and less formal training. A word of caution, however: Do not neglect to give a good rooting medium for Roses, and make every attempt to keep down insect pests.—COLIN RUSE, 35, West Road, Saffron Walden, Essex.

White Rose Ointment.—In reference to the making of ointment from Rose Blanche Belgique, mentioned in your issue for July 12, page 346, I have just received the following recipe, which I send on to you: "The Roses Pettles must be dry or the Ointment will go Mieldew, Homemade Lard: or Frest Butter from the Chure with aut Salt in it then Simmer in an Eaithen Pipken (Miss Anne have one) Put as Mency Rose leaves

knew Miss Anne liked all those sort of old things." I did not know its particular use till the grey-haired writer of the preceding recipe said, "I see you've got an old ointment pipkin, Miss Anne, like my mother used to make her white Rose ointment in years a-gone, and you've got the old ointment Roses in your garden too. I ain't seen any of them since I was a child." I do not know where the Rose is now to be obtained. The bushes in my garden are evidently extremely old, and I have hitherto failed to root any cuttings from them, although I have often tried to do so, as all my friends who see and smell them desire to have a bush of them.—ANNE AMATEUR.

Beautiful Floral Combinations.—I think it may be of interest to those of your readers who are constantly on the look-out for new colour-schemes to instance the following combinations which I have noticed with especial pleasure in my garden during the present season. Masses of *Malva moschata alba* alternating with great drifts of *Campanula rotundifolia* (or one of its varieties) afforded a spectacle of rare and delicate beauty. The pure scarlet of *Lychnis chalconica* is a perfect foil for the equally pure white of *Lilium candidum*. Lastly, the, to my mind, somewhat acrid pink of Rose Dorothy Perkins is pleasingly relieved by breadths of *Viola cornuta* growing beneath. Too often the flowers suggested for combination disappoint us by their failure to blossom at the same time. I think no difficulty will be experienced in the case of those which I mention. It is, in my view, essential to the success of colour-schemes that considerable quantities of specimens of one species should be used, and I have purposely refrained from instance harmonies afforded by plants which from their rarity cannot be employed so lavishly as the nature of the case demands.—RAYMOND E. NEGUS, *Walton-on-Thames*.

—A pretty floral combination I saw recently was produced by Shirley Poppies and blue Cornflowers mixed together. The Poppies, unfortunately, do not last, but while they did, the mixture was exceedingly telling and produced at an expense of twopence for the seeds. Another equally cheap combination is produced by *Asperula setosa* and *Linaria aureo-reticulata* or *L. purpurea*, but the first *Linaria* is the better of the two. An annual I am very fond of, but scarcely ever to be seen, is that known as Lobel's Catchfly, the botanist's *Silene Armeria*. I have an *Antirrhinum* exactly the same shade of colour which I am hoping to use in combination with the former, its squat growth calling for a spiral-growing plant to get the most out of it. While on the question of combinations I may mention one formed by a group of *Crucianella stylosa* running through and intermixing with one of *Nepeta Mussinii* on a rockery. The first impulse was to separate them; but, dirty as the *Crucianella* looks, the colour blends very nicely with the *Nepeta*—another instance of the unexpected in colour combinations.—R. P. BROTHERSTON.

ROSE GUSTAVE REGIS AS A LARGE BUSH. THIS PLANT WAS OVER FIVE FEET HIGH.

in as you can and simmer slowly until it began to turn brown through a piece of muslin. I should think Enamel Sauspan would do as well. I remember the Rose leaves use to be Cramed In, when the leaves use to turn brown it was read to be Strain. the Ointment use to be white." The ointment was used for chapped faces and hands in winter, and on further enquiry I found that a little Friar's balsam was sometimes added to the ointment, and was told "the dry Rose petals was saved till we killed a pig," and "the ointment was kep' in china pots with china lids." The red earthenware pipkin is glazed inside and has a quaint handle. It is an antique one given me by another villager "because she

Musk Losing Its Scent. Respecting the loss of scent in Musk, to which there have been several references lately, I dare not affirm that it smells less Musky than in the past, because I do not recollect the scent ever to have been strong. And it is well to remember that the perfume of flowers varies to a very considerable degree. In some conditions of the atmosphere scent is imperceptible, and this is very noticeable with Roses, Sweet Briar especially, and with common Primroses, the perfume of which on a warm, almost sultry day pervades the air to such an extent that we seem to draw it in with our breath. How diverse in the strength of its perfume, too, is a field of Beans! And so with plants which smell badly. Some days one cannot pass a clump of Crown Imperials without being made uncomfortably aware of its presence by its foxy smell, which under other atmospheric conditions is not apparent at all. Last of all, we cannot leave out of account the state of the individual's organ of smell, which without a doubt alters not only with age, but with the condition of one's health. On the whole I should, therefore, be chary about saying Musk is Musk no longer.

Some Good Primulas. I recently had the pleasure of spending an hour or two along with Dr. McWatt in his garden at Morclands, Duns. It was too late for Primulas in general, but I saw the old and fine *P. sikkimensis* in fine condition, and a nice hybrid between *pulverulenta* and *cockburniana*, with the flowers like the latter and habit and pulverulence of the former. It is named *Lissadell Hybrid*. The last named, it may be added, is perennial in the Duns locality. Dr. McWatt finds a difficulty with common vulgaris in its double forms, a difficulty shared with others. All the same, a large border is occupied by a full collection of sorts not long broken up. One way the difficulties of Primula cultivation are lessened is by plunging the pots in sand kept wet to a good depth. There is space in the garden for a great variety of plants other than Primulas, at the expense perhaps of material for the cook, and flowers, consequently, are everywhere. Quite a good collection of flowering and other shrubs is also cultivated, a huge specimen of a *Phyllostachys* demonstrating the hardness of the Bamboo tribe in this cold district. A new rockery is in course of being furnished, and here, too, the ubiquitous Primulas were conspicuous. But Dr. McWatt is by no means prejudiced in his floral tastes, and works on Violas, Foxgloves and Delphiniums with the presence of the cultured and observant amateur.—R. P. BROTHERSTON.

FORTHCOMING EVENTS.

August 11.—United Horticultural Benefit and Provident Society's Meeting.

August 12.—Royal Horticultural Society's Exhibition. Flower Show at Clay Cross.

August 13.—Flower Shows at Carlisle (two days), Exmouth (two days) and Capel. East Anglian Horticultural Club's Meeting.

August 14.—Flower Shows at Taunton Deane, Merthyr Tydfil, Abingdon and Oxford.

August 16.—Shows at Ambergate, Seascale and Lake District.

August 18.—Shows at Warkworth and Pitsmoor (Sheffield).

August 20.—Shows at Shrewsbury (two days) and Wallingford. Banffshire, West Cumberland and Royal Jersey Horticultural Society's Shows.

August 21.—Flower Show at Aberdeen (two days).

THE GREENHOUSE.

THE AUTUMN PROPAGATION OF FUCHSIAS.

IF cuttings are inserted now, nearly a whole year is gained in the building up of fine plants suitable for pot culture or for the furnishing of the flower garden in the summer-time. I have propagated hundreds of cuttings at this season of the year, and they have grown into very nice plants by the following spring. Fuchsia plants are generally gradually dried off as the autumn passes. They are then stored in a place just safe from frost until the early part of the following spring, when the old ball of soil is reduced in size, the branches are pruned back as required, and the repotting is done in smaller pots. In dealing with the autumn-struck cuttings, the cultivator must keep them growing steadily throughout the winter months, simply repotting them in February or March as they need more rooting space. The growth made in the winter will not be great, but it is an advantage, and the autumn-struck plants will be one-third larger at the end of the following summer than those propagated in the spring of the same year.

Select strong young shoots growing near the base of the old plant; they make the best cuttings. If there are flower-buds on any of the shoots, remove them. Very few will appear on them afterwards during the autumn; any that form must be pinched off. Each cutting should be about four inches long. Cut out the two lower leaves and sever the stem just below a joint. Use a light, sandy compost, one made of loam and leaf-soil in equal proportions, with a small quantity of old mortar and pounded brick added, and sufficient coarse sand to render it all very porous. This complete porosity is necessary, as the plants will need occasional watering during the winter-time. Place the pots in a frame turned towards the north, and lightly shade the glass when the sun shines brightly. When first inserted, give the cuttings a good watering, afterwards maintaining the soil in a medium state of moisture. Occasional syringings on fine days will revive the foliage a great deal, and will do more good than a watering of the soil in the pots. If the soil is kept in a constantly saturated condition, the cuttings will not thrive well in it, and many leaves will be lost. If the cuttings are inserted round the edges of 5-inch and 6½-inch pots, they will be easily wintered on shelves in a warm greenhouse or in a heated frame. AVON.

SOME INTERESTING PLANTS IN FLOWER.

WHERE they have not been grown very warmly, some of the finest gesneraceous plants, such as the Achimenes, Gloxinias and Streptocarpuses, will be just now at their best. There is a great tendency to regard these different subjects as fit only for a warm structure; indeed, Gloxinias are often referred to as stove plants.

Gloxinias.—Where they are needed early, it is necessary to subject them to a considerable amount of heat; but in some cases at least their blossoms will be more appreciated during the latter part of the summer than earlier in the season. Given one year old tubers, Gloxinias may be grown under much the same conditions as Begonias; that is to say, they may be started in the spring in a gentle heat, and by the end of May artificial

heat can be readily dispensed with. From that time a cold frame is the best place for the plants, shifting them into their flowering pots as they need it. Gloxinias and, in fact, all gesneraceous plants are well served by a liberal use of good leaf-mould in the potting compost. Should the weather be cold after the plants are removed to the frame, it will be an advantage to shut the lights up early in order to husband the sun-heat. Grown coolly in this way, the leaves are of a better substance than they are in a warm and much-shaded structure, while insect pests give scarcely any trouble. The flower-stems, too, are more sturdy, so that less support is needed. Of course, where blossoms are required early, this cool treatment cannot be recommended; but for the production of flowers during the latter part of July and in August this is by far the better plan.

Achimenes.—The numerous varieties of these also form a charming feature in the greenhouse at this season, showing as they do a wide range of colour and a great profusion of bloom. Despite their desirable qualities, they can scarcely be regarded as popular plants at the present time, probably to a certain extent owing to the fact that they are of little service for cutting, a standard by which flowering plants are so generally judged nowadays. Still, for hanging baskets, to be at their best during the summer, there are very few classes of plants to equal the Achimenes, as when suspended the branches acquire a semi-pendulous habit of growth, which shows off the butterfly-like flowers to the greatest advantage. In commencing the culture of Achimenes, the best plan is early in the year to obtain a good selection of the dormant tubercles, when they can be sent by post for a few pence. These should be obtained from a reliable source, so that the collection may be as varied as possible. The tubercles may be potted three in a small pot, and when sufficiently advanced should, without disturbing the roots, be shifted into larger pots. Put several together into deep pans to make large specimens, or plant in baskets for hanging up. Potted about the beginning of March and placed in a temperature of 50° to 65°, they will soon grow away freely.

Streptocarpuses.—While Achimenes have declined in popular favour, Streptocarpuses have in the same time made great headway; indeed, the present garden forms are of quite recent origin. This class of plants is remarkable for its comparatively large, showy blossoms, the great profusion in which they are borne, and for the wide diversity in colour that now exists among them. Few flowering plants are the equal of the Streptocarpuses for growing in a structure where they get a good deal of shade. Streptocarpuses may be readily increased by seed, which, sown early in the year, will produce plants that will flower in the course of the season. Their period of usefulness is then by some considered to be over, but they may with advantage be kept and grown on for another year. They should during the winter be kept in a temperature of 50° to 60°, giving just enough water to keep the roots in good condition, as the Streptocarpus does not form tubers in the same way as the Gloxinia. The plants so wintered will, if shifted into 5-inch pots in early spring, grow away freely and flower well.

Gesneras, too, are lovely flowers, the earliest of which are now open. It is difficult to know, at least in some cases, which to admire the most—the beautiful marbled leaves or the spikes of drooping, tubular-shaped blossoms. There is a

wide range of colour in the flowers, but those of an orange tint, such as in the variety Orange King, which was given an award of merit three years ago, gain, as a rule, the most admirers. H. P.

DUTCH HYACINTHS TO FLOWER AT CHRISTMAS.

AN IMPORTANT DISCOVERY.

CARNATIONS and Lily of the Valley have long since "looped the loop," or done the equivalent acrobatic performance which in the floral world corresponds to it. Now Dutch Hyacinths are trying their hand to see what they can do. For the last year or two there has been a great shortage in the supply of Roman Hyacinths from the South of France. It was the Dutchman's opportunity.

In the course of my wanderings in Holland (for to me Holland is a word confined to the gorgeously-carpeted land where bulbs grow, and where, in the true Dutch fashion of things being contrary to the ordinary, the carpet is only laid down in spring and cleaned for the rest of the year), I say, in the course of my wanderings I found myself in the office of the most hospitable firm of Messrs. R. Van der Schoot and Sons of Hillegom. Pretatory to a look at the Tulips I was shown some things of great interest. One of them was the photograph which is reproduced herewith. "Come, come," I said "this is a bit of good. All this lot in bloom on December 15. Tell that to Mr. Jones" (the aforesaid bulb representative of one of our great horticultural firms was with me). However, I spoke too soon. A photograph is not the same

I hear some English firms are taking it up. For one, I believe the Busy "Bees" of Liverpool are very sweet upon this process and want to make it known to their British customers. I always have had a warm corner in my heart for this little people (A. K. B., the King Bee, must be 6 feet or over!) ever since they put the photograph of an exquisite bowl of Feathered Hyacinths, which in the flesh had done duty on my dining-room table and as a picture in the pages of THE GARDEN, in their catalogue. There must be a "Bee" everywhere, in Holland as well as in China. They gather together the good things of the world, and then dispense them from Sealand or Mill Street, Messrs. Barr also have some bulbs.

Now for the practical steps to be taken if we want these advanced Hyacinths in December:

- (1) Buy as soon as possible; the varieties on my list are good ones for the purpose.
 - (2) Be sure you get these specially-prepared bulbs.
 - (3) Pot before September 10 at the very latest.
 - (4) Avoid like poison, at any period of their growth, any bottom-heat.
 - (5) Start in the dark as usual, but in a comfortable atmosphere.
 - (6) Keep them nice and warm when growing.
 - (7) When I tried them I kept them too cool, so I am going to find out more about the exact temperature they like, and with the Editor's kind permission a note will appear on the subject either in next week's issue or the one following.
- JOSEPH JACOB.

SPECIALLY-TREATED DUTCH HYACINTHS FLOWERING ON DECEMBER 15 OF LAST YEAR. THESE WILL PROBABLY TAKE THE PLACE OF ROMAN HYACINTHS.

Few people outside the Dutch growers themselves realise the vast importance of the Hyacinth trade to the capitalists and bulb-farmers of the country. The sales for a long time have not been what they were in former days. The Cinderella of the bulb fields of a generation back has become the Princess, and the proud sisters of old (Hyacinths and early Tulips) have had their "noses put out of joint." A radical operation, or rather a series of smaller operations, was necessary to try to effect a cure—prizes at the big Royal Horticultural Society's Forced Bulb Show; a tardy acceptance of the "miniature" Hyacinth; and lastly, among the up-to-date men, such as Tuhergen and Van der Schoot, the "advanced" cure.

as a newspaper. What it contains is correct. All these were in flower when it said. Who the inspired genius was who first hit upon the plan of prematurely lifting and then artificially drying and baking the bulbs I do not know (Was it Mr. Dames of IJisse?), but this much I do know. Thanks to some man and his followers, Hyacinths can be so prepared or advanced that with ordinary greenhouse-treatment they can be had in bloom in December. Lady Derby, L'Innocence, Yellow Hammer, Schotel, La Tour d'Auvergne, Grand Vedette, Grand Monarque, General Pelissier, Linnæus, Grand Vanquer, Cornelia and Distinction lend themselves especially to this treatment. The gain is great; not only a whiff of spring, but a peep of spring in December.

Pans about two inches deep are very convenient for its reception. These should be clean and effectually drained. A mixture of loam, leaf-mould and sand passed through a sieve with a one-third of an inch mesh is very suitable for the seed, some of the roughest portions of the compost being placed immediately over the crocks. The surface of the soil being pressed down moderately firm and made level, the seed should be sown thereon and covered with about a quarter of an inch of soil. Gently watered, the seed germinates quickly, so that by the end of the summer or in early autumn the seedlings may be potted singly in small pots. In this way they will by February be ready to shift into pots 4 inches in diameter.

H.

HIPPEASTRUMS FROM SEED.

WHERE it is desired to raise Hippeastrums from seed, those that flowered at about the normal season will by now be ripe or nearly so. The question sometimes arises whether it is better to sow the seed at once or to keep it until the spring. My experience is that, providing there is a structure with a gentle heat where a temperature of 50° to 60° can be maintained during the winter, the seed had better be sown with as little delay as

THE FLOWER GARDEN.

INTERMEDIATE, EAST LOTHIAN AND BROMPTON STOCKS.

THESE are useful subjects for either beds, borders or pots, while they are highly prized as cut flowers, both for their exquisite colours and pleasing fragrance. The Ten-week Stock is a well-known and popular plant, and, where occasional sowings are made, a grand display is kept up for several months. It is, however, to the Intermediate, East Lothian and Brompton Stocks that I would call particular attention at the present time. They may be had in separate colours, such as crimson, white, scarlet and purple, or, for an amateur, a good mixed strain would give, perhaps, the greater satisfaction, and, if bought from a reliable firm, a large percentage of doubles, bright in colour, would be secured.

The East Lothians are dwarf and compact in habit, producing immense spikes of bloom somewhat resembling the Hyacinth. The Intermediates are very floriferous, and are employed on a large scale for pot work, quantities being sent to Covent Garden and other markets during the spring months. The Bromptons form huge bushes when well grown, and possess a robust constitution. Although it has been stated that the plants quoted above thrive best in the cooler parts of these islands, good results can be obtained in the warmer regions, especially if a full south aspect is not chosen. Seeds may be sown either in June and July or in February, the former for flowering the following spring and summer, and the latter for autumn flowering. If sown in February, a little heat is necessary, and the plants will require a gradual hardening off prior to planting in the open ground.

The usual plan is to sow in June, July, or early August in any part of the garden which happens to be vacant, but the soil must be made fine, and, if at all dry, a good soaking with water is advisable. When they have made three or four leaves they should be transplanted into a cold frame or in small pots, so that the frost can be excluded during the winter; and in March they may be removed to their permanent quarters. In some winters they will live out in the open ground, but it is necessary for the soil to be well drained, for I think excessive moisture at the root is more injurious than frost, providing the plants are fairly dry at the base.

Stocks succeed in almost any garden, but they are worth taking a little trouble with, and, wherever possible, the ground should be deeply dug and liberally manured the previous autumn. Once planted, further attention is hardly needed, except keeping the surface stirred about with the hoe; and if the weather should prove exceptionally dry, an occasional watering with weak liquid manure will prove of considerable benefit. S.

RAISING PANSIES FROM SEEDS.

THE Pansy is a grand border plant for the amateur gardener to grow. In small gardens, where large and especially tall-growing subjects are out of place, or seem to be, dwarf ones, such as Pansies and Violas, look very charming indeed. These plants are equally beautiful and suitable for growing in the largest flower garden, too. They are much favoured in Northern gardens, but I have seen as fine displays in Southern gardens. It is a matter of good culture, mainly. In one case whole beds were filled with Pansies in as good condition as

any I have ever seen, both as regards health of plant, quantity and quality of flower. The soil was very sandy. Many seeds are sown in shallow boxes. I certainly do not favour these, as the soil in them so soon dries up, and, in order to maintain it in a moist state, very frequent watering is necessary. Only in exceptional instances should the seedlings be raised in boxes. It is much better to sow the seeds in the open border, selecting one in a cool position. There is ample space in the open border, so the seeds should be sown very thinly indeed. When the young seedlings have plenty of space to develop, the seed leaves grow to a large size, roots are formed freely and the rough leaves grow strongly. The plants are thus given a good chance in their early stages of growth, and it is a greater pleasure to transplant them to nursery beds than the puny specimens grown overcrowded in a small box. Whether planted in their flowering beds in the autumn or retained in prepared nursery beds until spring, one transplanting in a young stage will be sufficient. Drawn-up, weakly plants bear small flowers on long, slender stems; the dwarf, border-raised seedlings have huge, well-coloured ones on short, stout stems. Anyone may raise Pansy plants and grow them fairly well with ordinary care, but much care must be bestowed on them if the very best results are to be obtained. When in their summer quarters surface mulches must be put on and faded flowers regularly removed; then the flowering season will be prolonged. Neglected plants quickly degenerate. G. G.

CLOVER IN LAWNS.

I HAVE read with interest the references in recent numbers of your paper to the subject of Clover in lawns, and I venture to make some remarks based on the experience of an agriculturist rather than that of a gardener. Any of your readers who chance to follow the transactions of the various agricultural societies and colleges doubtless know that a vast amount of experimental work is done to discover the best means of renovating pastures. The subject is full of difficulty, but, broadly speaking, success or failure depends on whether one is able or not to produce a free growth of white Clover. Now, no gardener under any circumstances wishes Clover on a tennis lawn. No gardener, again, who has a first-class lawn wishes Clover. Neither does any gardener who has a tolerably good lawn, which he wishes to improve, desire Clover. How to obtain that end is well known. Every spring give a light dressing of nitrogenous manure.

But there are many gardeners who have thoroughly bad lawns which they wish to improve. To these I venture to commend the beneficial effect of white Clover as a slow, but as the only sure, means of bringing on the finer grasses, which in a lawn, just as in a pasture, constitute the test of excellence. If nitrogenous manures are applied right away to a poor lawn, the coarse, healthy grasses will benefit at once, while the finer grasses, on account of their starved, unhealthy condition, will benefit too late to escape being crowded out.

I may perhaps be allowed to indicate the best-known methods of encouraging Clover as well as the finer grasses. In the first place, those materials must be supplied which are essential to both Clover and grass. These are lime and phosphate. Basic slag contains both, and is a truly marvellous manure. Unfortunately, it is also the trickiest of all fertilisers. It works miracles on some soils, while on others it is absolutely

worthless. Unless the gardener knows that slag suits his land, he should not waste time on experiments, but should apply lime in the form of slaked lime-shells, and phosphate in the form of the most finely-ground bone-flour he can get. The standard dressing of bone-flour which is considered payable in agriculture is half a ton per acre (equal to a quarter of a pound per square yard). This will endure for from six to ten years, and must be applied in autumn. Of lime, double the above dressing should be given, also in autumn. On heavy land this may endure for ten years; on light land for very much less.

In the second place, the gardener will seek to encourage Clover. Now, Clover hates nitrogen and loves potash. One will, therefore, avoid the former and give potash. Muriate of potash is the easiest to apply, and the dressing is 2oz. per yard, which is enough for very many years. All these manures (lime, bone-flour and potash) may be mixed and applied together, and all can be bought in small quantities from a first-class firm which caters for retail trade. I may warn the reader that both lime and bone-flour are very powdery, and that the work of application is not exactly tidy. There is this to be said, however, that the dressing is lasting, in contradistinction to nitrogenous applications, which endure for one season only. LANDOWNER.

GARDENS OF TO-DAY.

TREGOTHNAN, CORNWALL.

SITUATED about five miles from the ancient town of Truro, and not far from the South Coast, is Tregothnan, the beautiful seat of Lord Falmouth, by whose kind permission we are enabled to place before our readers a few particulars of the interesting, and in many ways unique, gardens there. It was during the early days of April when we were privileged to visit Tregothnan, a time when the gardens of Cornwall are usually regarded as of the greatest interest, because the feature of most, and Tregothnan in particular, is the rich collection of choice flowering and comiferous trees and shrubs, which in less-favoured parts of the British Isles need the protection of a glass-house to rear them successfully. In writing of Cornish gardens it is necessary to make this point quite clear.

The Rhododendrons are a great feature in many Cornish gardens, where their flowers usually open at least a month in advance of those of the same varieties near London. At Tregothnan several of the walks, and also the main carriage drive, are bordered with enormous Rhododendrons, the massive trunks of many testifying to their great age and the genial climate of the district. In one part of the grounds is a superb plant of Rhododendron Falconer, a perfect specimen of its kind, standing over twenty feet high and measuring as much in diameter, the brown stems and bold leaves creating a picture of rare beauty even though flowers were absent. Chinese Rhododendrons, including most of the newest varieties, are grown on an extensive scale; and we were specially interested in a fine plant of R. Keysii, the small, coral red flowers of which are clustered together much in the same way as are those of an Aloe.

The House Walls.—Naturally, in a garden such as this, one expects to find the walls of the mansion

A BEAUTIFUL SPRING BORDER AT TREGOTHNAN. PREPARATIONS FOR A BORDER OF THIS KIND MUST SOON BE COMMENCED.

put to good use, and in such a favourable climate to find many rare and choice things nestling under the shelter that the walls afford. On the south front we found such plants as *Prostranthera rotundifolia* fully bejewelled with its dainty little blue flowers, *Cytisus fragrans*, *Clematis indivisa* (a plant which we also found scrambling over a tall Oak tree in another part of the garden), *Calceolaria violacea*, *Sollya heterophylla*, and in the border a plant of *Abe serratifolia* in full flower. On the east side such plants as *Acacia riceana* and *Camellias* thrive amazingly, imparting to the surroundings quite a tropical appearance. Reverting to the south front, the terrace is supported by a low retaining wall, part of which is shown in the accompanying illustration. Under the shelter of this such plants as *Acacia verticillata*, *Correas*, *Boronias heterophylla* and *megastigina*, and *Coronilla glauca* find a happy home, while in front of it we found one of the most charming spring borders that we have ever been privileged to see, and part of which is shown in the accompanying illustration.

company with large trees of the Blue Gum, *Eucalyptus globulus*, *Pittosporums*, and the so-called *Mimosa*, *Acacia dealbata*, which sends up suckers yards away from its main stem. In another

Choice Shrubs and Trees.

—These abound on every hand at Tregothnan, and in an article of this description it is impossible to mention anything like all the interesting and beautiful plants that we saw. In the shrub border running from the east side of the mansion we saw a magnificent plant, about six feet high, of the crimson-flowered *Leptospermum scoparium Nichollii*, a species which secured the cup offered for the best new plant at the International Show at Chelsea last year. It will be news to many of our readers to learn that a plant of such size exists in this country. Keeping it company were a goodly host of rare shrubs, including *Drumys Winteri*, *Embothrium coccineum*, *Buddleia Colvillei*, *Ferigoa sellowiana*, *Crinodendron Hookeri* and *Cianthus puniceus*. In another part of the gardens we found a plant of *Berberis Wilsonii*, 5 feet in diameter, keeping

direction *Cytisus proliferus* was flourishing, its white and rose coloured flowers being produced freely.

Palms, Tree Ferns and Dracænas.—The hardy Palm, *Trachycarpus* or *Chamaerops excelsa*, abounds in the gardens at Tregothnan, and this, together with large, tree-like examples of *Dracæna indivisa* and, in some of the woodland glades, the Tree Fern, *Dicksonia antarctica*, impart to the gardens a subtropical appearance that is quite characteristic of Cornish gardens. The Palm mentioned might certainly be grown in many sheltered gardens in the London district, and it is possible that the *Dracæna* would also thrive if protected in the early stages of its career, and we hope the illustration of this, which shows the plants bordering the broad walk leading from a dainty little summer-house that faces south, will induce some at least of our readers to try them. The walk shown in the illustration leads down towards the water garden, through a spacious, rolling lawn, in which are beds filled with *Azaleas* and, at the bottom, two of the finest beds of a distinct variety of the Mediterranean Heath, *Erica mediterranea*, that we have ever had the pleasure of seeing. The head-gardener, Mr. Andrews, told us that he had raised all the plants that we saw in the beds. It has an erect, columnar habit, and flowers with almost embarrassing freedom. From these beds one could have cut armfuls of flowering sprays without them ever being missed, and the air for yards around was permeated with a perfume that one rarely encounters outside a highland moor. The view from the summer-house, at the top of the path shown in the accompanying illustration, is of rare beauty, looking as it does over miles of undulating, well-wooded country.

The Water Garden.—This is a charming feature at Tregothnan, and one that its owner is justly proud of. Situated in a large, natural depression and well surrounded by tall trees, the three placid pools, each on different levels and all connected by miniature cascades, provide a peaceful and delightful home for all kinds of aquatic plants. Here the happy visitor may enjoy, to the music of babbling water and sighing Bamboos, such plants as *Primulas pulverulenta* and *kewensis*, *Water Lilies* and *Cape Pondweed*, *Gunneras*, the young, sword-like foliage of many *Trises*, and,

THE BROAD WALK AT TREGOTHNAN, WITH TALL PLANTS OF DRACÆNA INDIVISA ON EACH SIDE.

if he be observant, under the spray of the largest cascade that gem of the Filmy Ferns, *Todea superba*. Even so early in the year this water garden was a peaceful place of great charm; but later in the summer, when the numerous and rare plants have fully developed, it would be even more beautiful and interesting.

Primroses in the Woodland.—The countries of Devon and Cornwall are, of course, famed the whole world over for their Primroses, which seem to thrive in any nook or corner that provides lodgment for a square inch of soil. Even in the gullies of the roadside we found them flowering happily, but it was in the woodland glades at Tregothnan that we had an optical feast of these beautiful natives which will live long and pleasantly in our mind. Broad stretches of these, flinging themselves in riotous profusion under the tall Beeches that stood like sentinels over them, seemed as though Nature herself had designed it all, placing there the giants of the vegetable world to give shade and shelter to their lowly brethren, and also to the more brilliant, though none the less pleasing, Bluebells that were to follow later.

Camellias.—We have purposely deferred mention of these until the last, because in a way they are a special feature of Tregothnan. In many parts of the grounds one finds large plants of robust appearance, but it is on the walls of the stables where the most wonderful plants in probably the whole of the British Isles are to be found. These walls are about thirty feet high, and extend for about fifty yards, the whole surface being completely covered by Camellias, which were planted many years ago. Last year all these plants flowered with considerable freedom, and the sight at that time can be more easily imagined than described. Even when not in flower the handsome, dark green, glossy foliage has a quiet beauty of its own that Ivy, or, indeed, any other evergreen suitable for the purpose, does not possess. Such, then, are the gardens at Tregothnan; a genial home for all that is good, beautiful and interesting in plant-life, and much of which might, with a little perseverance, be grown outdoors in sheltered gardens on the West Coast of England, Southern Scotland and the coast of Wales.

ROCK AND WATER GARDEN.

THE ROSETTE MULLEIN.

(*RAMONDIA PYRENAICA*.)

THIS beautiful Rosette Mullen has been quite a favourite in the rockery for many years, and at the present time a rock garden is not complete without it. It is perfectly hardy, requiring to be grown between the stones in a light, well-drained, damp, peaty soil, but on no account exposed to full sunshine, which is detrimental, causing the plant to shrivel and die. It was thought by many at one time that a more or less vertical wall in the shade was absolutely essential

for its success, but it is now generally known that it can be grown on the flat surface in the open, providing, as already mentioned, the plant is not too much exposed. Others worthy of cultivation are *alba* and *rosea*, two beautiful forms of *R. pyrenaica*, and *R. serbica* and its charming variety *Nathalia*. They are all easily raised from seeds, which should be sown in pots as soon as ripe, or by the leaves, which should be broken off close to the plant and the rootstalk inserted into moist, sandy peat and kept close. F. G. PRESTON

TREES AND SHRUBS.

THE MOCK ORANGES.

THE various kinds of *Philadelphus* or Mock Orange form a valuable group of June-flowering shrubs,

the *Lemoinei* group, require regular pruning. This must be done about the end of June, or as soon as the flowers fade, and pruning should consist of the removal of all the old flowering wood, cutting it back close to the ground should there appear to be plenty of young shoots growing from the rootstock, or, if young shoots are scarce there, to the strongest shoot appearing from the flowering wood. The object in view is the production of long, well-ripened wood, which if properly matured will blossom from end to end during the following year.

Propagation.—This is not difficult, for if cuttings of young shoots 3 inches to 4 inches long, with a slight heel of old wood, are taken during late June or early July and inserted in sandy soil in a close and slightly warm frame, roots are formed in the course of a few weeks. Some people insert

A BEAUTIFUL COLONY OF THE ROSETTE MULLEIN, A GOOD PLANT FOR A SHADED ROCK GARDEN.

the majority of which are quite suitable for general planting throughout the country. A few are tender, but their exclusion need not have any serious effect upon the general usefulness of the group, for the perfectly hardy sorts are sufficiently numerous and varied in habit to offer a wide choice to the most fastidious person. Moreover, they are among the easiest of shrubs to cultivate, and, given moderately good soil, they occasion little further trouble once they become established. A surface-dressing of well-decayed manure, however, every second year is attended by good results, this being particularly necessary in the instance of the dwarf kinds, which are hard pruned each spring.

Pruning.—Large-growing species and varieties require very little pruning other than an occasional thinning out of a little of the older wood; but the dwarf kinds, more especially the hybrids of the

cuttings of fully-matured wood, 9 inches to 12 inches in length, in outdoor borders during late autumn or winter, but the earlier cuttings are usually the more satisfactory.

About a score of species have been introduced, but about half-a-dozen, in addition to numerous hybrids, only are generally grown. Some of them are natives of the United States, others are found in China and Japan, while one or two have been collected in other Asiatic countries. The best for general purposes are the following:

P. coronarius, the common Mock Orange, or *Syringa*, is a widely-distributed Asiatic shrub. Under normal conditions it is met with from 8 feet to 15 feet in height, with a considerable spread, and bears large white or creamy coloured flowers freely. There are several varieties, but they are, as a whole, inferior to the type. *Dianthiflorus plenus* and *flore pleno* are forms with double

flowers; *foliis argenteo-variegatis* has silver variegated leaves; *foliis aureis* bears golden leaves, which are pretty in the early stages, but lose their colour early in the summer; and *nanus* is of dwarf growth. *P. tomentosus* is sometimes looked upon as a distinct species, and is distinguished from *P. coronarius* by its more hairy character.

P. grandiflorus is an exceptionally fine plant from the Southern United States. Of vigorous growth, it sometimes exceeds twenty feet in height, while it often has a very wide spread. The flowers are white, shapely and quite 2 inches across, with a similar fragrance to that of the Asiatic species. Two well-marked varieties may be procured—*floribundus*, which blooms with remarkable freedom, and *laxus*, a variety of somewhat looser growth than the others, but equally floriferous.

P. inodorus, another Southern United States shrub, is hardly so useful as the species previously referred to, but it may be planted in gardens where the owner objects to the powerful scent of other species, for its flowers have little, if any, fragrance.

P. Lewisii is a native of Western North America, and it forms a large, shapely bush 12 feet high and as far through. At its best it is very showy, for the clear white flowers appear in profusion; but, unfortunately, it cannot be relied upon to blossom well each year.

P. mexicanus is only suitable for the warmer parts of the country, for it is somewhat tender. A native of Mexico, it forms a shrub 5 feet or 6 feet high and bears large white flowers of exquisite shape and fragrance.

P. microphyllus is the dwarf of the genus. Mature plants are about two feet in height, and are composed of a mass of slender, wiry branches bearing small, ovate, greyish leaves. The white flowers are deliciously fragrant, and are about three-quarters of an inch across. It is as a parent, however, that its value has been most known, for crossed with *P. coronarius*, it was the means of *P. Lemomei* being raised. The advent of that plant saw one of the best flowering shrubs of modern times put upon the market, and in any collection of twelve select flowering shrubs it is probable that *P. Lemomei* or its variety *erectus* would find a place. Left to their own devices, the *Lemomei* type form bushes 4 feet high; but it is usual to prune them hard each year and retain only young shoots. By this means plants 2½ feet to 3 feet high are obtained, which blossom profusely, the flowers having the delightful fragrance which is characteristic of *P. microphyllus*. There are several of these dwarf kinds, some having single, others double, flowers. Of the set, perhaps *P. Lemomei erectus* is the most useful; but *Avalanche*, with very large flowers; *Boule d'Argent*, with double blossoms; *Fantaisie*, with large, white, flatish flowers, with a shade of rose in the centre; *Gerbe de Neige*, *Candélabre*, *Mont Blanc*, *Pavillon Blanc*, *Rosace*, a variety with semi-double flowers between 2 inches and 3 inches across; *Virginal*,

a double-flowered form; and *purpureo-maculatus* are among the best. The last named is conspicuous by reason of its white, fragrant flowers having purplish centres. There are numerous other forms which might be used, but those mentioned will be found sufficient for most gardens. D.

THE ROSE GARDEN.

PREPARING SOIL FOR ROSE GARDENS.

THE time for laying out new or renovating old Rose gardens is fast approaching, and I would suggest that more than usual care be bestowed upon this all-important subject. So much depends upon the preparation of ground and the proposed forms of beds and borders, also more

that Roses are as much grown in our crowded suburbs as any one other subject, now that we have such an improved choice to select from. Not only are they freer in blooming, but that many of our very choicest can be grown as well proved by the numerous superb stands so often found in the local classes, both in the metropolis and the largest and most thickly-populated provincial towns. It has often been a source of surprise to me to find such grand flowers at the provincial exhibitions of the National Rose Society as we almost always do. The classes for Roses grown within a radius of six, eight and ten miles of Charing Cross must come from any but the pure country atmospheres formerly considered indispensable. It is a matter of preparation and a judicious selection of varieties. In both cases much depends upon local circumstances; nor is there need for so much expensive labour in soil

preparation as many apparently think. A little common sense directed towards drainage and the thorough overhauling and improvement of one's subsoil will go far towards success—may, perhaps, make all the difference between success and failure. So often the best of our suburban soils have been transferred before building operations take place. If this is not the case, they are frequently buried under the worst possible material in the matter of foundation excavations, together with the unconscionable dumping down of builders' refuse in the shape of spare cement, glass, old paint refuse and heaps of other matter detrimental to all forms of plant-life; so by all means take the first opportunity of thoroughly overhauling the soil to a depth of 3 feet at the very lowest, should there be the least doubt of its constituents. This complete moving will do much good in itself, and there could be no better time to ascertain what the ground is deficient of and to add or take away accordingly. I do not mean to say a lot upon this subject, but it is such a pity to miss the opportunity of a more favourable start than many secure, all the more so when the veriest tyro must realise the value of a properly-prepared basis. A. P.

ROSE CYNTHIA FORDE, A BEAUTIFUL FREE-FLOWERING VARIETY FOR GARDEN DECORATION.

ROSE CYNTHIA FORDE.

care in the selection of varieties that are best suited to each spot and purpose, that one may well wonder at the little forethought so often displayed. Let us bear in mind that we shall never have a better time for thoroughly preparing the soil by deep digging, manuring and any necessary drainage. Such a grand opportunity cannot occur again, and it is folly not to take full advantage of it.

That Roses can be successfully grown in a large and varied number of places and soils is well attested by the grand blooms invariably seen at any representative exhibition of our national flower, for do not these come from all over the kingdom? Nor is it so absolutely necessary to have the pure atmosphere of country life, as was thought for a long time. Indeed, I fancy one may safely state

paratively recent introduction this variety must take a prominent position, owing to the charming colour and form of the flowers, its vigorous branching habit and freedom of flowering. Raised by Mr. Hugh Dickson in 1909, it has quickly come to the front in many gardens. Although the blooms are rather flat, they are of exquisite form, as will be seen in the accompanying illustration. The plant makes a shapely, branching bush, and the blooms, which are bright rose pink in colour, are borne in clusters. Notwithstanding this, they are of large size, and there is no necessity to disbud, as many are so apt to do indiscriminately. At shows where vases of garden Roses are asked for, this variety would make a very telling bunch, as its long stems would enable the exhibitor to arrange it tastefully.

GARDENING FOR BEGINNERS.

HOW TO FORCE EARLY BULBS IN POTS, PANS AND BOXES.

THE forcing of plants that are suitable for the purpose is always very interesting work, but the forcing of bulbs is fascinating as well, particularly to the beginner. In a very short time beautiful leaves and lovely, fragrant flowers are obtained from dry, hard bulbs simply by putting them in soil and subjecting them to moisture and temperate heat. Some who would like to force various kinds of bulbs are deterred from doing so by want of confidence in themselves, and because they think it is absolutely necessary to be able to command a high temperature.

The Soil.—An old compost is better than a new one, and if it has been mixed and kept in an open shed for two months prior to being used, it will be more suitable still. Fibrous turf, which has been stacked for two or three months, and sweet leaf-soil, a little more than half-rotted, should be used in equal quantities. To a bushel of the combined parts named add a 7-inch potful of sand, and put a handful of well-rotted manure in the bottom of each pot on the rougher portion used to form a part of the drainage, and before any of the general compost is put in. The roots of the bulbs will benefit from the manure in due course; but it is not wise to mix the manure with the soil generally, nor to so place it that the bulbs come in direct contact with it.

Potting and Boxing the Bulbs.—It is bad policy to place too many bulbs in a pot. Three Roman Hyacinths in a 5-inch and four in a 6½-inch pot will be quite sufficient. Bulbs of *Narcissus Poeticus* and *N. Paper White* may be put in close enough together to allow of the fingers being inserted between them. Tulips and Freesias should be potted in a similar way. When boxes less than five inches deep are used for Tulips and Narcissi, then 1 inch more space between the bulbs

HOW TO POT BULBS OF DAFFODILS, TULIPS AND ROMAN HYACINTHS FOR FORCING.

should be allowed. All pots and pans must be clean and dry, especially the insides. Fig. A: No. 1 shows a *Narcissus* bulb of good size, and No. 2 how the bulbs should be potted, with the crowns about three inches below the surface of the soil. No. 3 denotes a Tulip bulb, and No. 4 the right

way to place the bulbs in a pot or pan with the crowns just visible above the soil. Nos. 5 and 6 show a Roman Hyacinth bulb and the right way to pot it respectively. With regard to Freesias, it is very important that the largest and firmest bulbs be potted. Small specimens, such as the one shown at No. 7, would only produce a mass of "grass," but no flowers. The one shown at No. 8 is the right kind to pot, as 95 per cent. of bulbs such as this will bear flower-stems. In every case pot pretty firmly, and bury the Freesia bulbs the same as those of the *Narcissi*. Fig. B: At No. 1 a box for bulbs is shown, No. 2 a Tulip and No. 3 a *Narcissus* bulb, and the right way to box each. Bury the pots or boxes under ashes—old ones, not new ones fresh from the furnace—sand or common soil. No. 4 denotes the pots containing the bulbs, and No. 5 the empty, inverted pots put on to protect the new growth from the pressure of the covering material. No. 6 shows an uncovered bulb pot. The position may be an open one or against a fence or wall, as shown at No. 7. When the new growth has advanced as much as shown at No. 8, remove the pots from the ashes. Sometimes it is necessary to transplant the growing bulbs from boxes, and make up pots of them for special purposes. The right way to do this is shown at No. 9. No. 10 denotes the drainage and rough compost, No. 11 the finer portion, and No. 12 the way to place the bulb and surround it with soil. No. 13 shows how to fix the stake for supporting a Hyacinth spike without damaging the bulb, No. 14. When removed from the ashes keep the bulbs in a cool frame for a short time, and transfer them to the greenhouse as required. From the time the flower-stems show plainly, give water more freely and also feed the plants.

G. G.

THE BULBS MAY ALSO BE GROWN IN BOXES. ALL MUST BE PLUNGED IN ASHES OR SAND AFTER POTTING OR BOXING.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Violets.—Continue to keep these well hoed and watered when necessary, keeping an eye on the under side of the foliage so that spider does not get a footing. All runners should be removed as soon as they appear, as if these are allowed to develop they will considerably weaken the parent plant.

Annals.—Some of the early-blooming annuals, such as Shirley Poppies, Clarkias, Candytuft and Viscarias, will be going out of flower, and rather than leave them to make the borders look untidy, they should be cleared out at once. Sunflowers, both large and small, are now making a good show, and to prevent damage by wind, a stake or stakes should, where necessary, be put to them.

Asters generally are not so good this season, owing, no doubt, to the serious drought we experienced at the time of planting out. Ostrich Plume, Comet and smensis are all varieties that are grand for cutting. Sutton's Fire King is exceptionally good as an edging to a border, while as a bedder this firm's Pink Beauty is hard to beat, it being quite pyramidal in form and of a pleasing colour; height about eighteen inches.

The Rose Garden.

Climbing Polyantha Roses.—By this date most of the Polyanthas will have gone out of bloom, and should be pruned forthwith. Where the young growths are likely to prove of sufficient length to cover the pillars or arches, all the old wood may be cut out right to the base where the young growths spring from; but where a greater length is desired, two or three of the best two year old growths must be retained for extension, just cutting the flowering growths to a wood-bud. Electra, Tea Rambler and one or two other early-flowering Roses that were pruned in mid-July are now growing strongly, thus giving testimony to the good of early pruning or thinning. Many of the wichurianas, such as Albéric Barbier, Leontine Gervais, Gardemia, Sylvia, René André and others, should not be pruned just now on account of their foliage, which will continue to look bright and effective till the autumn. Dorothy Perkins and Hiawatha, though wichurianas, are not so showy in the foliage; hence they may be pruned as soon as blooming is finished.

Budded Stocks.—Standards and early-budded dwarfs should have the ties loosened, or, as the stocks swell, the matting is apt to cut into the wood.

Mildew.—Where this is troublesome, the plants should be syringed weekly with sulphide of potassium, half an ounce to a gallon of water, or the autumn crop of bloom will not be of much use.

Plants Under Glass.

Roman Hyacinths.—To secure early blooms Roman Hyacinths should be potted up at once, or at least as soon as they are received from the nurseryman. For cutting purposes boxes will do as well as pots, though, where they are required as pot plants, 4½-inch and 6-inch pots are desirable.

Paper-White Narcissi.—These also should be potted up as soon as received, it being quite essential to get them well rooted before introducing them to heat.

Freesia refracta alba.—Part of the stock of this sweetly-scented bulbous plant should also be potted, reserving the others for late batches. Four and a-half inch pots are the most useful, with about seven or eight bulbs in each pot. A moderately light, rich compost suits them well, and after potting and watering in they may be placed in a frame, putting the lights on only in the event of very wet weather, though to keep the pots from drying they may be covered with an old mat or two, or a light sprinkling of leaf-soil, till the growths begin to push, when they must have all the light and air possible.

Arum Lilies.—It wanted for decorative purposes, the best of the tubers should be potted singly in 6-inch pots, while for cut flowers they may be potted several in a pot, according to its size. A good, rich compost should be used, consisting of loam, short, well-rotted manure and

sand. Pot firmly, and place them in a frame or a semi-sheltered position out of doors where they can be carefully watered till growth commences.

The Kitchen Garden.

Late Peas that may be developing mid-way should be sprayed with a weak solution of sulphide of potassium about once a week, and if the weather continues dry, a good watering should be given. A good *donche* overhead as watering proceeds will also tend to keep them growing freely.

Celery.—After a really good watering and feeding, all early Celery should be partially earthed-up. Any decaying leaves and side growths should be taken off before tying, which should be done before the soil is brought up to the plants, cutting the matting again as the soil is made firm around them, the ties, if left, sometimes tending to deform the sticks.

Silver-Skinned Onions should be moved out of the soil a little as soon as the tops show signs of withering. These subjects are not required as large as one can get them, so it is as well to hasten their ripening as much as possible.

Fruits Under Glass.

Melons that are now setting their fruit should be carefully looked after, and wherever possible three or four fruits should be set on each plant. Where only one or two fruits are set on these late plants, they are apt to get unduly large, and do not ripen so well or get so good a flavour as the smaller fruit. From now onwards there is not quite the vigour in the plants that is seen in the spring, so that great care must be exercised both in the watering and feeding.

Strawberries.—Perpetual-fruiting Strawberries intended for autumn fruiting under glass may now be allowed to develop their flower-trusses, and if a good airy house is available, they may be placed in this. Well spray between the plants so that spider does not develop, or the crop will be ruined, and as soon as the fruits are nicely set, a dressing of Le Fumier may be given to swell them.

THOMAS STEVENSON,
(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Daffodils. Everyone should have some of the older and cheaper varieties, such as the following: Trumpets—Empeter, Glory of Leiden, Mme. de Graaff, Mme. Plomp, Weardale Perfection, with their bicolor varieties, Empress, Horsfieldi and maximus; Mock Narcissus—Barri, conspicuus, Eggs and Bacon, Sir Watkin and Minnie Hume; Poeticus—Burbidge, John Bam and poetarum. Among more recent introductions the following moderate-priced varieties can be recommended: Trumpets—Fairy, Golden Bell, Hamlet, Lord Roberts, Master of Balliol and Monarch; whites—Alice Knights and Lady Audrey; bicolors—Glory of Noordwijk and Trewhiddle Bicolor; Mock Narcissus—Homespun, Beacon, Circle-t, Eye-bright, Oriflamme and Seagull; Poeticus—Baccharolle and Virgil.

Propagating Pansies and Violas.—September is probably the best month for propagating bedding Violas, but Pansies and exhibition Violas should be propagated this month. Cuttings will strike quite well in the open behind a wall or hedge, and if a frame is used it should face north. For these it will be more convenient to use boxes.

Propagating Bedding Plants.—A few varieties of bedding plants should be propagated this month. These include Heliotropes, Fuchsias, Iresnes, Verbenas and a few others. A mild hot-bed should be prepared and allowed to cool down before placing the cuttings on it, and those who possess a spent hot-bed from the spring operations would do well to utilise it. Keep close during the day, but admit a chink of air overnight.

The Seedling Garden.

Pricking Off Seedlings.—Where sowings of Dianthus, Campanulas, &c., were made in May or June, the resulting seedlings will now be ready for

pricking off. Sandy loam will suit the majority, but layers of peat or lime must have their requirements met. In all cases it is better to avoid a rich soil. Boxes or pans will be found the most convenient, as a rule; but extra valuable plants had better be potted in 2½-inch pots, and the pots plunged in some open material, such as Cocoanut fibre. Keep rather close for a week after the operation, and then increase the ventilation by degrees.

The Rose Garden.

Pinching Shoots.—This requires attention throughout the growing season, and as the season advances the need for it rather increases, as at this period many varieties, especially those with a vigorous habit, such as J. B. Clark, Hugh Dickson and Mme. Abel Chateau, are apt to send up one or two extra vigorous shoots, to the detriment of the others. If the points of these are pinched out, it will check them for the rest of the season, and thus equalise the flow of sap.

Mildew is often persistent during this month, and must be checked by sulphur in some form.

Plants Under Glass.

Cyclamens.—Young plants which are the result of seed sown last August will now be ready for the final potting, and, generally speaking, 6-inch pots will be suitable. A mixture of equal parts of turfy loam, good leaf-mould and sand will be found suitable if a proportion of cow-manure and guano or other similar fertiliser is added. Use the compost in a rather rough state and pot rather loosely. Replace in the frame and continue to sprinkle overhead twice a day for ten days or so, after which this attention should be discontinued. Give abundance of light, but shade from midday sun for a few weeks yet.

Begonia Gloire de Lorraine.—As the pots get filled with roots, mild and frequent feeding should commence. Attend to staking and tying as growth advances. Vaporise on the first appearance of thrip.

Fruits Under Glass.

Figs.—Trees on which a second crop of fruit is swelling must have the assistance of some fairly strong liquid manure, and care must be taken that they are not allowed to suffer for lack of water. Maintain a moist atmosphere and a brisk temperature until the fruits begin to ripen, when it should be slightly reduced and rather more ventilation given.

Melons.—Where the crop has been gathered and no second crop planted, the soil should be cleared away and the house in every part be thoroughly cleansed for the reception of such subjects as *Salvia splendens*, *Begonia Gloire de Lorraine*, or *Cyclamens*, as the case may be.

The Hardy Fruit Garden.

Trapping Wasps.—As fruits ripen, wasps will be ready to pounce upon them, and unless they are destroyed they will work much harm. I saw a very ingenious and apparently efficacious wasp trap this season, but it is not on the market yet. Numbers, however, can be lured to their doom by placing some jam and sugar with a proportion of water in narrow-mouthed jars, which should be placed near the fruit trees. A look-out should also be kept for nests, and when found they should be promptly destroyed. Hanging nests can be demolished by means of a torch formed of "waste" or rag tied on the end of a cane and saturated with petroleum. Those in the ground should have tar poured into them. The work must be done late in the evening.

The Vegetable Garden.

Earthing-Up Celery.—The main crop will now be fit for a first earthing-up. As suggested in the calendar a few weeks ago, it is worth while tying up the plants with raffia first. See that all side growths are removed.

Spinach.—Towards the end of next week a good sowing of Spinach should be made on a south border for spring use. I find that a summer variety, such as Victoria Round, succeeds as well as the Prickly Spinach.

Sowing Cabbages.—Make a sowing of three types for spring planting, say, Ellam's Early, Early York and Winningstadt.

CHARLES COMFORT,
Broomfield Gardens, Davidson's Mains, Midlothian.

NEW AND RARE PLANTS.

Carnation Rosy Morn.—This is one of the handsomest border Carnations we have seen, though deep cerise, we think, most accurately describes the very remarkable tone of colouring. It is a pure self-coloured flower, with thick petals and strong supporting stems. From Mr. J. Douglas, Great Bookham.

Sutton's Red Sunflower.—This is the name by which it is hoped to popularise what is undoubtedly a great garden annual. The predominant colour is crimson and brown, the tips of the florets golden. The flower-heads are 6 inches to 8 inches across. From Messrs. Sutton and Sons, Reading.

Rose Annie Crawford.—This is reputed to be a seedling from Captain Hayward and Mrs. Sandford. It is of a shade of pink akin to Mrs. J. Laing, but fully twice its size. It is really a giant. From Mr. R. Hammond, Grovelands, Burgess Hill, Sussex.

Sweet Pea King White.—A very handsome pure white variety.

Sweet Pea Dobbie's Lavender.—A delightful tone of lavender. Both from Messrs. Dobbie and Co., Edinburgh.

Dendromecon rigidum.—A glorious golden Poppwort from California, not new, but very choice. In sheltered gardens it is hardy, but in others may require the protection of a wall or even cool greenhouse. From Sir Trevor Lawrence, Bart.

Nymphæa Colossea.—The name is suggestive of a giant flower, and this is the fact. Indeed, we believe it is the largest variety extant. The colour is white, the base of the flower being suffused with a delightful shade of pink. The anthers are golden.

Nymphæa Escarboncle.—The colour is the deepest crimson, and in this respect surpasses all comers. These were shown by Mr. Leopold de Rothschild, Gunnersbury House (gardener, Mr. J. Hudson).

Spiræa (Sorbaria) arborea grandis.—At first sight this bears resemblance to *S. lindleyana*, though the creamy plumes of flowers are stronger and more erect. It should make a splendid plant in isolation. From the Hon. Vicary Gibbs, Elstree.

Clematis tangutica obtusifuscula.—A pretty yellow-flowered form. The flowers are drooping and produced solitary on the branches. From Mr. F. C. Stern, Goring-by-Sea.

Gloxinia Veitch's Strain.—A very remarkable strain of these popular greenhouse flowers, from seeds sown in January last, was staged. It was representative of almost every shade of colour and of the highest merit. From Messrs. James Veitch and Sons, Limited, Chelsea.

All the foregoing were shown before the Royal Horticultural Society on the 29th ult., when each received an award of merit.

Hydrangea arborescens grandiflora is one of the comparatively few good hardy shrubs that flower freely in August. It makes a neat bush some three feet or rather more high, each stout growth being surmounted by a large head of creamy white flowers. For filling a large lawn bed this *Hydrangea* would be excellent.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ABOUT IRISES (W. C. A.).—Yes, the Iris is attacked by the Iris leaf-spot disease, due to the fungus *Heterosporium gracile*. Spraying with Bordeaux mixture or with ammoniacal copper carbonate acts as a check to the spread of the fungus, but we find the best thing to do is to apply lime liberally to the soil before the Irises are planted. A very good time to transplant or to propagate Irises is late June or early July, just as the new roots are being formed from the old growths.

FLOWER BORDER AND YEW HEDGE (M. H. M.).—In making your herbaceous border near a Yew hedge it will not be advisable to place the plants very close to the hedge, for on the one hand the roots of the hedge will interfere with the herbaceous plants, and on the other hand the herbaceous plants will injure the lower part of the hedge. If possible, it would be well to leave a space of at least 3 feet between the foot of the hedge and the herbaceous plants. *Iris sempervirens* will continue to grow and flower for many years. All the attention it requires is the cutting away of old flower-heads as soon as the flowers fade. *Cheiranthus Dillonii* often lasts two or three years in good condition, but it is advisable to renew it frequently.

SCABIOSA CAUCASICA FAILING (E. P.).—The remedy is with the soil. In heavy soils this fine subject frequently refuses to root at all, but ramifies freely in lighter soils and grows and flowers abundantly. In your case, if you desire continued success, you will have to lighten and improve the soil and raise seedlings periodically, planting them out in spring. Such good plants are worth much to make them a success, for we certainly have not too much of blue or mauve in the garden at any time. In addition to making the soil lighter, add lime freely to the soil six months in advance. When incorporated with the soil, the lime has the effect of precipitating the superfluous water to a lower level. In this way it is warmed, aerated and drained as by a single action. In any case you should go on till you succeed, since seeds may be had cheaply and we know of no better plant to experiment with.

PENTSTEMONS FAILING (E. P.).—The plants should certainly be in flower now, and obviously they have failed from some local cause of which we have no information. To secure the finest results, some old plants should be cut down in August to about half their height, and the freshly-made cuttings taken when about three inches long. If you can make a cutting on, say, 6 inches of ashes, and above this place a 3-inch layer of sand, you will have a propagating medium of the very best. Water thoroughly and keep moderately close for about a month, when the cuttings should be rooted sufficiently for planting in 3-inch pots. If you cannot do this, give the cuttings more room at the start and leave them in the frame, protecting only in the case of severe frosts. We imagine the fault to be with the soil, and the Pentstemon prefers a rooting medium midway between light and heavy. Incorporate leaf-mould and sand with the soil, adding lime freely to ensure more perfect drainage.

SWAINSONAS LOSING THEIR FOLIAGE (A. R.).—Your Swainsonas must have received some decided check to cause them to lose their foliage now. What this is we, of course, cannot say, there being so many possibilities. They may have been allowed to get too dry, or perhaps too wet, while a change from a warm house to a cooler structure would tend to bring about this trouble. If the plants have been grown in a partially-shaded greenhouse and were placed out of doors without gradually hardening them, then some of their leaves would be likely to drop. You say nothing about the treatment the plants have received, and this, of course, handicaps us greatly in replying to your question. At all events, we should not advise you to cut down your plants now, as Swainsonas should in the ordinary course of events flower throughout the summer. If in pots, the bareness at the base may be relieved by associating them with other plants, and, in fact, the same will apply if they are bedded out during the summer, for which purpose Swainsonas are often used. With regard to their culture, it should be borne in mind that they are natives of Australia, and therefore in this country they require the temperature of an ordinary greenhouse plant.

SWEET PEAS DROPPING BUDS (An Engineer).—Your Sweet Peas have probably become too wet at the root, or are in some way suffering from trouble there. This is the usual cause of bud-dropping. Your plants are *Spiræa Umaria* fl.-pl. and *Ceanothus azureus*, so far as we can say from the very poor specimens sent.

LILIES DISEASED (L. B.).—We cannot trace any insect boring, but find the Lily is attacked, in a similar way to that so frequent in the case of the common white Lily, by the fungus *Botrytis cinerea*. We recommend you to remove all the diseased and dying stems and the top few inches of soil from the plants, replacing the soil with fresh containing as little organic matter as possible.

LILIES GOING WRONG (C. P.).—Your soil is evidently teeming with all sorts of pests, and among them are millipedes and earthworms, both of which are capable of bringing about the damage shown by the plants you send. We recommend you to lime the soil thoroughly and do all possible to admit plenty of air and make it sweet. Vaporite or Apterite may be of use in checking the pests, but it is apparent that liming is particularly called for.

DOUBLE ROCKETTS (T. Hay).—The photographs you send show excellent results of growing one of the finest of so-called old-fashioned herbaceous plants; but unfortunately they are not suitable for reproduction. We have never seen any red or crimson variety, and doubt whether such exists to-day at all. At one period the Double Rocket was of a sportive nature, and varieties were quickly made. The *rubro plena* of Messrs. Rollinson's 1875 catalogue was of a pale rose colour, and never merited the term "red." At that time only a few small plants existed, and in 1877 or 1878 were practically non-existent.

SAXIFRAGA COTYLEDON PYRAMIDALIS (A. Elsas).—This is the name of the plant of which you sent a photograph. The flowering spike is more densely crowded than usual, and otherwise is good of its kind. The rosette dies after flowering, but as both off-sets and seeds are produced, you will be able to increase your stock, should you so desire. *S. burseriana* grows but 3 inch or 2 inches high, forming a spreading, prostrate tuft of leaves, over which in its best forms the blossoms of pure white, the size of a shilling, are scattered. The blossoms, too, are produced singly, i.e., one on each stem, and usually appear in February.

DEEPLY-PLANTED IRIS GERMANICA (T. A. S.).—If too deeply planted, this should be remedied at once, otherwise the best time for replanting is March and April. The rhizomes of these plants should be practically on the surface, and during the operation the plants had best be freely divided also. The single sectional part of the rhizome (rootstock) made during the present year is ample as a single plant, though a dozen of these might be arranged at intervals of a few inches in order to form a group. These Irises are not likely to flower if the rootstock is buried; they require sun to ripen them. Gather the Lavender just prior to the flowers fading, and expose the sprays in trays to the sun.

ANNUAL STOCK-FLOWERED LARKSPUR (M. C. L.).—There is not the least doubt that your cold and heavy soil is responsible for the greater part of the failure in these plants, and soil pests the remainder. The plants delighting in light soils and root warmth, the remedy is with the soil. Cannot you grow them in a bed apart, making the soil more congenial to the plants by the free addition of sand, leaf-soil and light manure? In very light and sandy soils the seeds of these plants may be sown in the open ground in March, but in the case of heavy soils they would be best sown in pots and subsequently transferred to the open ground; they are too sparse-rooting to succeed after transplanting in the ordinary way. If none of these appeals to you, try sowing a few seeds in pots of light soil. The pots should not be less than 8 inches in diameter, and could be plunged in any position you choose.

HARDY PLANTS FOR MARSHY GROUND (K.).—In such a position you might make good use of many plants, though the variety will depend to some extent upon the exposed condition of the situation. For example, if comparatively sheltered, *Phyllostachys niza*, *Bambusa palmata* and other Bamboos would do quite well; if not, they had better be left alone. Of undoubted hardiness are such as the Royal Fern (*Osmunda regalis*), *Spiræa gigantea*, *S. venusta*, *S. digitata*, *Gnucera scabra*, *G. manicata*, *Saxifraga peltata*, *Lilium pardalinum*, *Marsh Marigolds*, *Ranunculus lingua*, the *Bulrush*, any of the tall-growing *Lysimachias*, *Lythrum roseum superbum*, *Iris sibirica* in variety, *Narcissus* *Emperor*, *N. Poeticus* fl.-pl., *Camassia esculenta* and others. Indeed, it is surprising how large a variety of plants thrive in such places, while a little thoughtful work at planting-time will render them as attractive as other parts of the garden.

WATER LILY POOL (John Gray).—We presume there is too much sand in the clay, hence it is not impervious. In the circumstances you had better excavate 9 inches of the clay and discard it, replacing it by a 6-inch-thick bed of concrete of about four to one, i.e., four of clean ballast to one of cement. Over this place an inch-thick bed of washed river sand and cement of one and one strength, i.e., equal parts of each. At 9 inches from the surface reduce the thicker layer of concrete to one-half this thickness, while, if the position admits, you may turf the upper one down to the water edge. The naturalness or form of the whole is in your own hands, and a natural pool would have a very pretty effect. You would require a water depth of about two feet and a soil depth of about six inches. A greater naturalness to the whole would result were you to excavate to twice the above given depth and by a slight increase of the water depth, only leave at the bank-like slope to the pool ample room to

plant moisture-loving subjects here and there. We know of no book that will help you.

MADONNA LILY BULBS DISEASED (*M. Harris*).—The Lily has apparently been attacked by the disease induced by the fungus *Botrytis cinerea*. We have noticed that Lilies exposed to frost and cold draughts are more liable to the attack than are those in more sheltered situations. Lime in the soil also checks the trouble to some extent, but no perfect cure is known.

TREES AND SHRUBS.

CONIFERS TO PLANT IN A CHESTNUT WOOD (*A. H. R.*).—The two best conifers to plant in the Chestnut wood referred to in your letter are *Abies pectinata* (the common Silver Fir) and *Picea excelsa* (the common Spruce). It would, however, be a good plan to plant a few Beech trees among them. As rabbits appear to be present in quantity, considerable care will be required in fencing, otherwise every young tree will be ruined. Better results will be obtained by planting trees 12 inches to 18 inches in height than by planting larger ones, more especially in the case of the Fir and Spruce. Pit planting will be preferable to notch planting, and if a little trouble is taken in breaking up the ground for a space of 3 feet or so about the roots, the plants will stand a better chance of success than if the soil were left hard.

PLEACHED LIME TREES AS A SCREEN (*M. M. K. C.*).—There is no reason why you should not form a screen by the use of pleached Lime trees such as you describe, for it would not be likely to seriously affect your herbaceous border, although the Lime roots in time are bound to enter the border and thus deprive the plants of some of their nourishment. If you could plant them 5 feet or 6 feet from the wall, it would be possible to dig a trench near the wall every few years and cut the roots through. That would not injure the trees much and would save the border. The following kinds of Clematises would be likely to suit your purpose: *C. montana*, *C. m. rubens*, *C. lanuginosa*, *C. Beauty of Worcester*, *C. Enchantress*, *C. Grand Duchess*, *C. La France*, *C. Lord Nevill*, *C. Marie Lefebvre*, *C. Jackmann*, *C. J. alba*, *C. Mme. Edouard André*, *C. Mme. Grange*, *C. Sensation* and *C. coccinea*.

ROSE GARDEN.

SPORT OF TAUSENDSCHON (*J. G. K.*).—This Rose will often throw off pale, nearly white blooms. If you can send us a flower, we shall be able to inform you if it is of any value. Enclose a shoot, so that we may see if the growth is true.

ROSE SPORT (*J. G.*).—We cannot think you have a sport. Rather should we say you have had sent you the wrong variety. The Rose is not that of Molly Sharman (Crawford), and a sport rarely varies in its growth (save climbing sports) from the parent variety. We believe the Rose is Mrs. Arthur Munt.

STANDARD ROSES NOT FLOWERING (*T. W.*).—If the trees were not pruned in spring, you cannot well do so now, but if pruned and they have made the tiny shoots you speak of, we advise you to tie them over umbrella fashion. If it does not make them bloom this season, it will assist in laying the foundation for bloom next year.

MANURING WICHURAIANA ROSES (*M. S. F.*).—We think a dressing of basic slag applied in October at the rate of 6oz. to a square yard would give you the necessary lime, and at the same time supply phosphate to improve the blooms. A dressing of well-decayed farmyard manure could follow, and both should be dug under at once; then, in spring, give a dressing of bone-flour at the rate of a good handful per plant.

OLD CLIMBERS BLIGHTED (*Dormans*).—We think you would do well to severely prune the red climbers next autumn, but do not think it will be necessary to grub them out. We advise you to give the Roses a good dressing of commercial formaldehyde diluted to a strength of one tablespoonful of the 40 per cent. article to a gallon of soft water. Double this strength may be used in winter. It should be applied every week or ten days, and although it is now very late to begin, we think, if you persist in it, the blight will be very considerably checked.

ROSES DROOPING (*Miss Beddington*).—The Roses you send are mainly Maman Cochet, and this is one of the most unsuitable kinds you could plant as a bedding Rose. Its proper place is against a south wall, where the warmth would encourage its very double flowers to develop. It is a Rose that objects to too much manure; in fact, if grown in quite a poor soil it is best for it. Of course, the present season has been all against such Roses, they being very susceptible to wet, which causes the petals to stick together; then the whole bloom rots away. If the outside petals could be released before decay set in, the blooms would open all right. We advise you to remove the plants to a warm border and train them upon a wall or fence, replacing with good kinds of the Lady Roberts type, which you say has done so well.

THE GREENHOUSE.

PELARGONIUMS DAMAGED (*H. J.*).—The rotting of the stem of the Pelargonium seems to be due to the presence of myriads of bacteria in the stems. It would be well to discard these plants entirely. It not infrequently happens that cuttings fail to heal, after being put into the soil to root, rapidly enough to prevent the entrance of bacteria, and these then rapidly work great havoc. Kindly send flowers of your new variety, when we can better advise you of its value.

FRUIT GARDEN.

AUTUMN-FRUITING RASPBERRIES (*Grace Gardener*).—The autumn fruiting of your Raspberry canes will practically ruin them for next season. Plenty of other excellent growths will push up yet, and you should select five or six of these for retention.

GREASE-BANDS FOR FRUIT TREES (*Greystoke*).—These should be put on in October and re-greased once a month until the end of February. This is an excellent remedy against attack from Codlin and winter moth and the larvae of other species which eat the foliage of fruit trees in spring.

PEAR-LEAF BLISTER (*W. H.*).—The variety Thompson seems to have had its foliage exposed to cold winds or draughts, and the others are suffering from an attack of the Pear-leaf blister mite (*Oriophyes pyruli*). They should be sprayed with caustic soda (1lb. to ten gallons of water) during winter, or with paraffin emulsion.

INJURY TO MELON FRUITS (*D. M. L.*).—We suspect cockroaches to be eating the young Melons, though perhaps crickets are the culprits. If so, they should be trapped, using a jar sunk in the ground and having a little beer at the bottom, or one of the "V.T.H." slug traps, which we have found excellent for capturing cockroaches. You may ascertain which the culprits are by examining the plant after dark.

SPOTS ON APPLE LEAF (*A. J. B.*).—The brown spots are due to the attack of the fungus *Cladosporium horbarium* upon the Apple leaves. It seems more usual for this fungus to attack leaves slightly damaged by frost or by cold winds than where the leaves have suffered no check. We recommend attention to the provision of shelter, wherever possible, and the spraying of the trees liable to attack early in the season with Bordeaux mixture.

MORELLO CHERRIES WITH FORE-RIGHT SHOOTS (*R. P. H.*).—Cut all the fore-right shoots back to within four buds of their base now, and at the winter pruning cut further back to within two buds of their base. By this treatment fruit spurs and blossom buds will be formed, and fruit borne in due time. You must not let your trees get too dry at the root at any time. This, no doubt, is the cause of the fruit dropping this year.

PEACH LEAVES DROPPING OFF (*Peach Leaf*).—Your Peach trees under glass are affected by what is termed shot-hole fungus. The attack is usually caused by a chill through admitting too much frost air when the wind is cold and the young leaves tender. The best remedy you can apply is to dredge the foliage completely, both under and over, with sulphur, leaving it on for two days, shading the house in the meantime, and then syringing it off. Burn all the old leaves as they fall, give abundance of air day and night (except in very rough weather), and encourage the growth by syringing morning and afternoon and by careful watering.

MILDEW ON BLACK HAMBURG GRAPES (*F. W. R.*).—The most common cause of an attack of mildew, such as your Grapes are suffering from, is from opening the front ventilator too wide in the cold weather, when the vine is warm from gleams of sunshine. This causes a chill to the Vines and at once invites an attack of mildew. The best thing you can do is to heat the hot-water pipes (not too hot), and then paint them over with flowers of sulphur mixed with water to the consistency of paint. It should be done in the evening of a calm, damp day. This prevents the sulphur fumes caused by the heat of the pipes being blown away. Repeat the heating of the pipes and resulphuring the second evening. Theinery must be shut up, of course.

TRAINED MULBERRY TREES NOT FRUITING (*Meredith*).—Mulberry trees are always a long time in bearing fruit after planting (unless their roots are confined in narrow and limited borders), chiefly in consequence of the too robust growth of branches and leaves they make while the trees are young. This is borne out by the specimens kindly sent. The treatment to adopt to compel them to bear fruit will be to severely root prune them in the autumn as soon as the leaves have fallen. This will result in the trees producing branches of shorter growth and moderate strength, such branches only as will produce flower-buds and fruit. The trees should receive no manure at the roots until they have been brought into a condition of fruit-bearing.

KITCHEN GARDEN.

PEAS DISEASED (*Petits Pois*).—Some of the symptoms of disease shown by the Peas are similar to those shown by plants attacked by *Thielavia basicola* at the root, but the roots sent are insufficient in quantity to enable us to say definitely the cause of the trouble.

TOMATOES DISEASED (*W. B.*).—The Tomatoes are attacked by the fungus *Cladosporium fulvum*, which is usually far more prevalent in houses kept too close and damp than where there is ample ventilation and a dry atmosphere. Spray the plants either with Bordeaux mixture or with potassium sulphide, 1oz. to three gallons of water.

MISCELLANEOUS.

WIREWORMS IN SOIL (*Tobies*).—A satisfactory method of preventing wireworms from damaging garden crops is to cultivate the soil thoroughly and frequently. Hoing is especially useful. You can now only try to drive them away by dusting or hoing in one or other of the soil fumigants, such as Vaporite or Apterite. The sowing and digging in of mustard is often a useful measure, driving away the wireworms and at the same time adding organic matter to the soil.

ORGANIC MANURE FOR A CLAY SOIL (*Cartside*).—We think you would obtain better results on a heavy clay soil from using straw litter manure than from peat moss. The former will not only be less liable to render the soil acid, but will also tend to "open" the soil more—an important thing.

EPSOM SALTS AS MANURE (*W. B.*).—Epsom salts is chemically called magnesium sulphate. Soil is rarely lacking in magnesium in sufficient quantities for the use of plants; but if you desire to try its effects, dissolve 1oz. in two gallons of water, and water the plants now and again about three weeks hence.

MELON AND TOMATO DISEASE (*W. H.*).—Your Melon is apparently attacked by the Melon and Tomato canker (*Mycosphaema*). This disease must be notified to the Board of Agriculture. The plants not affected should be sprayed with Bordeaux mixture or with sulphide of potassium. The soil should not be again used for growing Melons, Cucumbers, or Tomatoes until it has been sterilised by steam heating.

FUNGUS ON DOORPOSTS (*J. S.*).—The fungus is a *Polyporus*, which destroys the wood, and will, no doubt, spread unless the conditions are made unfavourable for its development. The thorough impregnation of the wood with carbolineum or with copper sulphate would stop its progress, but merely painting the surface is unlikely to do so. The main thing to attend to is the ventilation of the surfaces, and that, from what you say, appears to be completely wanting.

NAMES OF PLANTS.—*W. H. J., Plaistow*.—1, *Eriothera vounghii*; 2, *Jasione perenne*.—*H. Etheridge*.—*Rose Celeste*, a variety of *R. alba*.—*A. B. C.*—*Achillea Ptarmica* The Pearl.

SOCIETIES.

CARDIFF HORTICULTURAL SHOW.

The twenty-fifth annual show was held on the 23rd and 24th ult. as usual in the Sophia Gardens, by the kind permission of the Marquis of Eute, and was quite a success. So numerous were the entries that an extra tent was needed for trade exhibits, which added much to the excellence of the display. Plants were meritorious. Cut flowers, especially Roses, were exceedingly fine. Sweet Peas are always a strong feature here; this year they surpassed any seen before. Fruit and vegetables were distinctly of a high order of merit. Mr. Maurice Bailey, secretary, had, as usual, everything well in hand. Plants were attractively displayed. Messrs. J. Cypher and Sons, Cheltenham, with one of their characteristic exhibits won the premier place for a group of miscellaneous plants arranged for effect. Palms, Crotons, Orchids and a choice assortment of other flowering plants were all harmoniously blended. Mr. D. MacIntyre, gardener to Lady Hill, Rookwood, was a good second. This exhibitor staged remarkable Fuchsias, pyramids 8 feet high, profusely flowered.

Mr. H. J. Pilcher, Penarth, was first for tuberous Begonias with extremely fine blooms, thickly studded on well-grown plants.

Cut flowers are a strong feature here. Roses had many classes provided for them. For twelve triplets there were five entries. Mr. J. Mattock, Headington, Oxon, won the premier place with high quality blooms of British Queen, Mrs. A. Coxhead, Mrs. W. H. Rowe, Mildred Grant, J. B. Clark and Mrs. T. Roosevelt. The King's Acre Nursery Company, Hereford, were a close second.

In the class for twenty-four single blooms, distinct, Mr. S. Treseder, Ely Nurseries, Cardiff, won the premier position with medium-sized, highly-coloured examples of popular varieties.

The King's Acre Nursery Company won for eighteen Tea or Noisette varieties with typical specimens of Mrs. Myles Kennedy and White Maman Cochet, for example.

A keen competition for twelve blooms, any one variety of other than Tea or Noisette, resulted in *Gloire de Chedane Guinoisan* carrying off the highest position for the King's Acre Nursery Company, a like award falling to the same firm for a similar number of any one Tea or Noisette with desirable blooms of Mrs. E. Mawley.

Groups of cut Roses occupying a space of 9 feet by 4 feet, with the use of Rose foliage only, were numerous and attractive. Mr. J. Mattock arranged a distinctly meritorious exhibit and worthily secured the leading award. Such sorts as *Ethel Malcolm*, *Lady Purrie*, *Lady Billington* and *Rayon d'Or* were shown in huge masses; these and the following Ramlers made a delightful display, which was much admired by visitors. *Dorothy Perkins* and its white sport, with *Philadelphina Rambler*, were conspicuously good. Mr. John Crossling, Penarth Nurseries, was second. Amateurs in smaller classes were creditably represented.

Carnations were much in evidence, helping to make the huge tent attractive. Border varieties with *Piceetes* receive encouragement here. A group to fill a space 6 feet by 3 feet was the leading feature. Mr. B. Lakeman, Thornton Heath, was first with high quality blooms, if not so numerous, a fine mass of the yellow *Cecilia* was admired. Mr. C. Wall, Bath, a noted exhibitor, was second with a fuller display but hardly the quality of the first prize group. The last named won for a display of Tree, American and Mahauton varieties, showing *R. F. Felton*, *Carola* and Mrs. C. W. Ward finely.

Border varieties with *Piceetes*, dressed and on stands, were numerous. Mr. Thomas Melhous was first for a dozen highly-coloured, shapely blooms.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Drying Herbs. All kinds of herbs should now be gathered. Tie them in bunches and hang them in an airy place to dry. When quite dry and brittle, strip off the leaves and rub them fine with the hands, and then store away for winter use in well-corked bottles. Lavender flowers ought also to be gathered, tied in small bunches and placed somewhere to dry.

A Useful Creeping British Plant. One of the most attractive of our native plants that adorn some of the most places in our country throughout the summer is *Lysimachia Nummularia*, commonly known as Creeping Jenny. For growing in pots or window-boxes in towns it will be found to be most valuable, the bright yellow flowers, like myriads of stars, almost covering the foliage, which hangs down from 18 inches to 30 inches in a very graceful manner.

A Useful August-Flowering Shrub. One of the best hardy shrubs flowering in August is *Olearia Haastii*, a native of New Zealand. It is a particularly useful shrub for small gardens, as it thrives well in towns and has the additional advantage of being evergreen. Growing 3 feet to 5 feet in height, *O. Haastii* has comparatively small box-like leaves, greyish green in colour, and during August produces a profusion of small, starry white blossoms.

A Dainty Hardy Annual.—*Ionopsisidum acule*, or the Violet Cross, was imported from Portugal sixty-eight years ago. This tiny but exquisitely beautiful hardy annual has never become a popular favourite, and why? Just because of its unobtrusiveness. Like all gems, it is only found when searched for. It only grows from 2 inches to 3 inches high, but its numerous tiny flowers of lilac, yellow and violet are very attractive. Sown in the crevices of the paved garden or on the rockwork, it appears to be quite at home.

The Purple Loosestrife by the Water-Side.—This is a very attractive herbaceous plant to use freely by the side of water and in damp, moist positions. Growing about three feet in height, the long, slender spikes of closely-packed flowers last in good condition for a couple of months—July and August. One important point is that no harm results from the flooding of the roots with water in winter, a condition which proves fatal to many plants. Even more showy and bright than the species is the rosy red variety, *Lythrum Salicaria rosea*.

International Horticultural Exhibition—Financial Statement.—The long-awaited financial statement of the International Exhibition held in May, 1912, is now issued. It is satisfactory to note that after providing for all liabilities, a profit has been made, and that charities have benefited. The Gardeners' Royal Benevolent Institution benefits to the extent of £1,532 18. 7d.,

while the following sums have also been allotted: Royal Gardeners' Orphan Fund, £700 0s. 10d.; Irish Gardeners' Association and Benevolent Society, £100; donation towards republishing Fritz Esch's "Botanical Index," £250. There is also a balance in hand for contingencies of £20.

A Pretty Effect Made by Rose Dorothy Perkins.—Visitors to Kew during the latter half of July and the early half of August have been charmed by this pretty Rose planted about the pond near the Palm House (on the Palm House side of the pond, and for a short distance along two other sides, the bank are held up by a wall, which stands ten feet or so clear of the water, but is only a little higher than the surrounding ground. For a distance of about twenty yards along the two sides the Rose has been planted, so that the branches fall over and almost touch the water. These, during the time mentioned, are perfect sheets of flowers, which contrasted well with the bright green leaves, and were reflected in the water below.

The Panther Lily. In *Lilium pardalinum*, the Panther Lily, we possess a particularly useful tall-growing Lily which flowers from the middle of July until the middle of August. A native of North America, the usual height is from 5 feet to 7 feet. Both leaves and flowers are arranged in whorls on the tall stems, giving the plants a distinct and stately character. Each stem terminates in a loose inflorescence of twelve to twenty blooms, rich orange in colour and freely spotted. It is what may be termed a good-natured Lily, for the bulbs appear to thrive equally well in peat or moderately light loam. *L. pardalinum* has large, rhizomatous bulbs, which increase rapidly. These should be planted 5 inches to 6 inches deep, as this is a stem-rooting species. One of the best positions for this Lily is in beds of *Rhododendrons*, where the stems will be screened from the hot sun.

An Orchid Hybrid Growing Wild.—Sixteen years ago an interesting hybrid between *Orchis maculata* and *Platanthera bilobata* named *Orchiplatanthera chevallieriana* was recorded as British, it having been found on a large moor near Perth among a profuse growth of the two parent species. It has now been found in a hayfield, close to the edge of a copse, about two miles from Shepton Mallett, Somerset. The finder, says the current issue of the *Orchid Review*, was Harry Stacy, a small boy, who recognised it as something unfamiliar to him. It shows an unmistakable combination of the characters of *Platanthera biloba* and *Orchis maculata*, which are said to grow in the same field, the flowers being white and unspotted, but with two ample rounded side lobes to the lip, an elongated front lobe and the spur nearly as short as in *O. maculata*, which it also approaches in the shape of the spike. It is an interesting discovery, and might encourage further search where the two species grow together.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Well-Flowered Phyllocactus.—I am sending you a photograph of one of my Phyllocactus plants, which is now in full bloom. The species is probably Cooperi. I have two plants, and have had seventy-two blooms on them this year. You will notice the amount of nourishment taken out of the lower leaves, though the plant has been continually fed with liquid manure and Clay's Fertilizer. By careful summer treatment I hope to have as good a result next year.—E. W. DUTTON, *Noak Hill School, Romford*

The Loganberry.—I read with interest Mr. Owen Thomas' article on "The Loganberry as a Commercial Fruit" in THE GARDEN of August 2, page 385, where he rightly emphasises its commercial value. Allow me to supplement his remarks on the training of this plant by saying that I think the best method of training is by means of a double wire trellis. By this method the fruiting canes are trained up one side and the succession ones on the other, transposing the order annually, of course. This keeps things tidy and gives the whole the maximum of light and air. One set of standards is sufficient, with cross pieces a foot long, furnished with an eye at either end to run the wires along.—C. C.

Scentless Musk.—The loss of scent in the common Musk, *Mimulus moschatus*, to which reference has recently been made, appears to be now so general in English gardens that it would be of interest to know how far this curious and lamentable condition has extended, or whether it is universal. May I be allowed to request readers of THE GARDEN in Scotland, Wales and Ireland, and also in foreign countries, to say whether this grievous loss of one of the charms of this good old plant also prevails with them? One would also like to ask botanists whether any scientific light has been thrown on the matter. I do not know how long it will take to reconcile me to this new state of things, but, for my own part, when I look at a flowering patch of Musk the old firm faith in its sweetness is so persistent, so impossible to dissociate from the appearance of the plant, that, until I actually take a piece and smell it, I cannot believe that the scent is gone.—G. J.

Rambling Roses.—A "Note of the Week" in THE GARDEN for August 2 on the beauty of Rose Lady Godiva encourages still further witness to the merit of this lovely late-blooming Rambler. It has all the freedom of Dorothy Perkins, from which it is a sport, but the lighter and more refined colouring—a tender salmon pink, shading from deeper to paler as the flower matures—makes it the loveliest thing in the garden in the last days of July. Another beautiful Rambler that should be more widely grown is Evangeline, a Rose of American origin. It is a single Rose, blooming in large clusters, the individual flower something like a Dog Rose, but larger and of firmer texture. It is very free, both of growth and bloom, and beautiful alike in the garden and in half-wild places. I have just noted how excellent this Rose would

be for grouping on a sunny bank with the wild Clematis Vitalba. Nothing could be better, planted in some quantity, in such a place as the mounds and banks that occur at the edges of a quarry, or on any broken or tumbled ground that there may be on the further edges of garden ground.—G. JEKYLL.

Open-Air Tomatoes.—The note under the above heading on page 376, July 26 issue, reminds me of a way of growing Tomatoes which I saw—it is now some sixty years ago—in the garden of an uncle of mine, who brought seeds of the, at that time in Germany, wholly unknown plant from America. He called them Paradise Apples or Love Apples. They were cultivated in rows much like we grow Potatoes, but instead of being planted on the apex of the ridges, they stood between rather high ridges in the valleys. Thus protected from wind, and warmth gathering around them, I can recollect them being in admirable condition, the glowing colour of the hundreds of fruits having made a deep impression on my

WELL-FLOWERED PHYLLOCACTUS IN A READER'S GARDEN.

juvenile mind. I am sure there was no kind of support in the way of tying up given them; they simply rested between the ridges. As I have never seen this mode of growing Tomatoes since, I thought perhaps it might interest your readers to know of it.—E. HEINRICH, *Planegg, Bavaria*.

The Altai Rose in August.—One of my plants of a favourite single Rose of mine, *Rosa altaica*, is again in bloom, and one is delighted to see its large white flowers once more. It frequently flowers a second time in autumn, and probably the other plants here will follow the example of this one a little later, especially if cooler and moister weather conditions should prevail. *R. altaica* is very acceptable as one of the earliest of the Rose species to flower, coming in May, when it gives the greatest abundance of its handsome white flowers. Those produced in autumn are not nearly so numerous. It is surprising to see how few gardens possess this fine Rose, which, either against a wall or in bush form, is very

handsome. One of my plants, against a 6-foot wall has long overtopped the wall, and is some 9 feet high at present. I like it best as a bush, however, and it is most graceful then. Like many of the Rose species, *R. altaica*, which is, by the way, classed as a form of *R. spinosissima*, was quite uninjured by the frosts which committed such havoc with the wickurianas and other Rambler Roses in Scotland last winter.—S. ARNOTT, *Dumfries*.

Raising Iris Kämpferi from Seed.—I think the enclosed photograph should be interesting as showing the extreme beauty of the single form of *Iris Kämpferi*. Some three years ago I sowed seeds gathered as soon as they were thoroughly ripe. I sowed the seeds in an ordinary 6-inch flower-pot, and there they remained, with the shelter of a cold frame, until the seedlings were large enough to be planted out. They were thus handled once only from the time of sowing until they flowered. From this single potful of seed I obtained 100 flowering clumps in the third season from sowing. Their range of colour is wide, varying from white to dark blue. The most beautiful shade, however, is lavender. All of the flowers are beautifully veined in the manner so well known in this species. The particular specimen illustrated has falls of pearl white, veined with dark blue, with yellow markings in the throat, and standards of pale purple. I think if Iris-lovers realised how simple is the culture of this queen of Irises, as indicated by the above note, *Iris Kämpferi* would be far more largely grown than is the case at present.—RAYMOND E. NEGUS. [Unfortunately, the photograph, which showed a good flower, was not suitable for reproduction.—ED.]

A Good New Thunbergia.—*Thunbergia Gibsonii*, which was given an award of merit by the Royal Horticultural Society on May 14 and was again shown on July 15, is a new plant of considerable promise. Botanically it may perhaps only be regarded as a form of the well-known *Thunbergia affinis*, but from a garden point of view it is very distinct and greatly superior to it. While *T. affinis* is of annual duration, *T. Gibsonii* is a

perennial, and can be readily increased either by means of seeds or cuttings. The branches naturally lie flat on the ground, though in all probability it could be trained as a climber. The flowers, however, form the dominant feature, being larger than those of *T. alata* and of an intense brilliant orange colour, a tint difficult to describe. When the plant is flat on the ground, the flowers are borne upright, or nearly so, on long, firm stems. They are attended by a couple of large hairy bracts, in colour green, striped with purple, from one side of which the flower protrudes. Being very amenable to ordinary culture and so readily propagated, there is little doubt but that this *Thunbergia* will before long be very generally distributed. For such a striking plant many uses will be found. It was introduced from British East Africa by W. Van de Weyer, Esq., Corfe Castle, Dorset. British East Africa is the home of many plants that grace our greenhouses and conservatories, and this *Thunbergia* is quite an acquisition.—H. P.

Spiræa Anthony Waterer. This delightful little bright-coloured shrub well merits all that is said in its favour in "Notes of the Week" in THE GARDEN for August 2. It should be, as there stated, pruned hard back in early spring, while I find a great incentive to a continued display of blossoms is to keep the old flowers cut off as soon as they get shabby, and to give the plants an occasional dose of liquid manure. Under this treatment they will bloom throughout the entire summer.

Erica hybrida.—Some years ago attention was directed to a beautiful winter-flowering hardy Heath which, under the name of *E. mediterranea hybrida*, had been put into commerce in a very quiet, unobtrusive way. In referring to this Heath a custom has of late arisen to drop the name of *mediterranea*, and simply call it *E. hybrida*. An instance of this is to be found in THE GARDEN for August 2, page 383. Inordinately long names are often a stumbling-block, but in referring to this Heath as *E. hybrida* confusion may ensue. It seems to have been overlooked that there is an old and well-known greenhouse Heath bearing this name, which, if priority counts for anything, cannot be ousted from its position. This Heath, with bright red flowers, is referred to in the "Dictionary of Gardening" as *E. hybrida*, and over forty years ago it was grown in quantity for Covent Garden Market. Even now it is listed by those who still grow the greenhouse Heaths. To avoid confusion the hardy kind should, therefore, bear its full title.

Gloxinias from Seeds.—Time was when it was considered necessary to propagate the better forms of Gloxinias by means of leaf-cuttings, but now, so carefully is the seed saved, that when obtained from a reliable source the very finest of flowers can be depended upon. The superior flowers borne on plants raised from seeds, and the short time necessary to obtain them, was well exemplified at the Royal Horticultural Hall on July 29, when an entire table was filled with perfect examples. The seed of these was sown only in January, so that the plants were about six months old, yet the size of the flowers and the number of buds still to develop would lead one to think that they were second season's plants. The leafage of the plants was also sturdy and of good substance, there being none of that floppy appearance so often to be found in plants that have been grown too warmly, a very common failing with many growers of Gloxinias. Such plants as those shown could be depended upon to keep up a fine display of flowers throughout the month of August, at which time some of the occupants of the greenhouse will be getting past their best. Grown coolly, Gloxinias do not require any fire-heat during the summer, but it is very essential that they be shaded from the sun's rays.—H. P.

FORTHCOMING EVENTS.

August 18.—Shows at Warkworth and Pitsmoor (Sheffield).

August 20.—Shows at Shrewsbury (two days) and Wallingford. Banffshire, West Cumberland and Royal Jersey Horticultural Society's Shows.

August 21.—Flower Show at Aberdeen (two days).

August 22.—Highland Horticultural Society's Show. Flower Show at Blairgowrie and Rattray (two days).

August 23.—Flower Show at Burnley.

August 26.—Royal Horticultural Society's Exhibition, Royal Horticultural Society of Ireland Autumn Show.

THE FRUIT GARDEN.

VINES IN AUGUST.

HINTS ON THEIR TREATMENT.

THE amateur cultivator who grows early and late ripening Grapes will find his Vines in a very interesting stage in August. He generally wishes to grow, say, Black Hamburgh, Foster's Seedling, or Buckland Sweetwater in the same structure that accommodates Alicante, Gros Colman, Madresfield Court and Muscat of Alexandria. Now, in order that each variety may be grown to a perfect finish, at least two houses should be devoted to these varieties, so if the amateur almost attains perfection in the one house, he must be satisfied. Bunches that are ripe and those commencing to ripen require slightly different treatment. We will presume that there are ripe Black Hamburgh and Foster's Seedling in a house where Alicante, Gros Colman and Muscat of Alexandria are just beginning to ripen. If the ventilators are small ones and can be worked separately, those nearest the ripe Grapes may be opened wider than those nearer to the late-ripening varieties. Except when the weather is very warm, a less quantity of water must be used generally in the damping of paths and borders; but in cases to which we now refer there need be no damping at all of borders immediately under the ripe Grapes. In the case of the latter, which are of the black varieties, a little extra growth of laterals may be allowed; but the laterals on the white varieties should not be retained in great numbers, as light is essential to good finish and helps to produce that amber tint we all like to see. Excessive covering created by the growth of lateral and sublateral shoots must not be permitted in the case of early-ripening black Grapes, as any undue shading would interfere with the proper ripening of the wood and basal buds thereon. A light shade for a period of two or three weeks will materially help to retain the blue-black colour of the berries; exposure to light gradually lessens it.

Watering the Soil.—After many years' experience I have come to the conclusion that Vine borders are in many instances overwatered. On no account must water be given while the soil is at all moist, but just before dryness sets in it ought to be well soaked through and any stimulating foods necessary applied immediately after. Then allow the soil to approach the dry state before watering it again. Surface sprinklings make the soil sour and then air is excluded, and as the roots of Vines must have air, an open, porous surface soil is of great importance. No manure of any kind must be given after the berries are coloured.

Fire-Heat.—Black Grapes always "finish" better when not subjected to a great artificial heat. If the pipes are kept very hot and the house rather close, black berries will not be of that blue-black colour so desirable. If it is necessary to have the pipes rather hot for the benefit of Muscats, ample ventilation should be given, and where there are early-ripening varieties in the same structure, place mats on the pipes passing under them. If subjected to much heat from pipes, Black Hamburghs, after full maturity, will quickly shrivel and lose flavour as the pulp dries. In the case of Muscats less flavour is lost through shrivelling. Judicious firing is always beneficial to late-ripening Grapes. AVON.

CULTURAL HINTS ON NEW AND RARE PLANTS.

HARDY PLANTS.

Anemone sulphurea.—This is, of course, neither new nor rare, though a rich yellow form of it, brought to an Inner Temple Show from Aberdeen by Messrs. Cocker a year or two ago, so impressed me by its superiority that I had hoped to test it beside my own. Soil occasionally, as well as climate and attitude, play important parts with such things, and those who would be up-to-date must be ever alert if they would garden with the best. This *Anemone* grows vigorously in clayey loam; less so in loams of lighter texture, though still making good headway. Seeds and division.

Wahlenbergia vincaeflora.—A fine new concerning this fine plant may cause many to plant it and obtain flowers during the present year. A frail and graceful subject of a foot or so high, it is endowed with flowers of the purest azure blue—a blue that is frequently referred to as "gentian blue," notwithstanding that some *Gentians* have flowers approximating to deepest violet and almost imperial purple. The plant is so profuse in its flowering, and so unmitable in colour among summer-flowering alpines, that it is a plant for all. Loves warmth, moisture when in growth, and a soil of peaty loam. Cuttings and seeds.

TREES AND SHRUBS.

Genista dalmatica.—The most suitable position for this dwarf shrub is the rockery, for when planted near coarse-growing subjects it is apt to become overgrown. Mature plants are from 3 inches to 6 inches in height, and except in stature closely resemble *G. hispanica*, the same spiny branches, small leaves and golden flowers being in evidence. It blooms very freely, and at its best is a mass of gold. Light, warm soil is necessary to keep it in good health.

Pierasma quassioides.—This is a medium-sized decorative tree, native of the Himalaya, China and Japan. Its pinnate leaves are from 9 inches to 12 inches long, and are peculiar by reason of their red stalks. The flowers are small and offer no special attractions, but the reddish bark is prettily mottled with brown. Its proper place is in a sheltered position on the lawn where the soil is well drained and of a rich, loamy character. Cuttings of ripened wood may be rooted out of doors.

Rosa Hugonis is the earliest of the species to flower, and though its usual flowering-time is early May, it sometimes happens that blooms are to be found during April. It is a vigorous grower, attaining a height of 8 feet or 9 feet; but the branches have a graceful poise and are clothed with small, elegant leaves. The flowers are about two inches across and yellow in colour. Similar cultural conditions are required to those given to other species. No regular pruning is necessary, and what little has to be done should take the form of thinning during summer.

Fabiana imbricata.—This is not a new shrub, but it is practically unknown, except as a pot plant, outside the South-West Counties. Although it belongs to the *Solanum* family, the leaves are more suggestive of those of a Heath, for they are very small and arranged closely together on the branches. The white flowers are tubular, nearly an inch long and borne in May. It succeeds as a bush in the open in the warmer counties, but must be planted against a wall elsewhere. Peru is its home, and it thrives in ordinary garden soil.

THE ROSE GARDEN.

THE BEST ROSES FOR BEDS.

AMONG the many recent improvements in Roses, there has been a most decided advance in the section now found so useful for beds or for massing in other parts of the grounds. A far more even and uniform habit of growth has been secured, as well as a better continuation of flowering; indeed, so greatly have we advanced in the last respect that we now have many varieties almost as free-blooming as the majority of other bedding-out subjects. Some little demur may, perhaps, be made about the extra labour and attention needed to keep our beds of Roses perfectly clean and healthy, without which, of course, any other subject cannot give entire satisfaction. Granted that there is some little extra work, are we not fully repaid by a good show of Roses, one of the most satisfying of all flowers whenever they may come? The old idea of mixed beds is dying out to a great extent, and rightly so, for there was not much harmony in growth and bloom when so many varieties were used in one bed or border. Whatever the size of bed or border, two or three varieties should be favoured rather than the uneven mixtures of former times, when, unless very careful selection was given, the varieties so quickly overbalanced one another in vigour and form of growth. This should not be with the grand selection, from all points of view, that exists now. We can have almost any colour, size, or form that may be desired; also plants to flower at any given time between the early June months and often later than the end of September.

Perhaps the most suitable bedders are those of rather less than average height, and all the more so when we avoid those varieties that have a tendency to produce erratic shoots either in the form of an occasional long rod or some side breaks that go completely away from the body of the plants. I would also avoid, as far as possible, any Roses that have a tendency to carry pendent blooms. I allude to what are sometimes styled the *Maman Cochet* section. Although that beautiful Rose *Lady Ashtown* is a capital bedder in the younger stages of its existence, when the flowers come more upright with me, it is often too drooping as the plants gain strength and carry blooms of greater substance. I am sorry to say a word against this and some other Roses, but to my mind it is of the utmost importance that all bedding Roses should carry themselves boldly erect, all the more so because we have to look down upon them, and a drooping posture does not show their chief beauty. It is somewhat different when this

class of Rose is made use of as standards, or upon walls and fences.

Another point I would like to bring to the notice of intending planters is the great advantages of using those varieties with upright and spreading trusses. *La Tosca*, *Lady Battersea*, *Peace*, *Coralina* and *Mme. Antoine Mari* are examples of what I mean. A variety that is not too double is also better suited for the purpose than any that are a long time in opening. The few named above produce a large number of buds, which expand readily and afford a fresh and pleasing show of bloom very quickly after showers and bad weather, and thus have a great decorative advantage over

ROSE ARTHUR R. GOODWIN, A BEAUTIFUL BEDDING VARIETY WITH ORANGE AND BUFF FLOWERS.

the heavier and slower openers. Moreover, very few of the latter are sufficiently free in blooming to make ideal bedders. Finally, be certain to ascertain the habit and height of growth each variety adopts before you plant extensively. There is not enough consideration given to this, nor to the most important item of how thickly to plant. This must depend entirely upon the habit and character of growth, and I feel sure a little care in these directions will be well repaid.

As some guide to intending planters, they will find the following list of varieties reliable. The colours in many cases would need a rather lengthy description because of their charming blendings,

but all may be found in any Rose catalogue that is fairly up to date. Deep maroon reds—*Victor Hugo* and *Etoile de France*. Scarlets—*Earlote*, *General MacArthur*, *Richmond* and *G. C. Waud*. Yellows—*Mme. Ravary*, *Duchess of Wellington*, *Le Progrès*, *Alice de Rothschild*, *James Coey*, *Mrs. Peter Blair* and *Marie van Houtte*. Deep salmon pinks—*Caroline Testout*, *Mrs. R. G. Sharman Crawford*, *Pharisæer*, *Killarney* and *Mrs. A. R. Waddell*. Salmony copper—*Dorothy Ratcliffe*, *Edu Meyer*, *Duchess of Westminster*, *Jacques Vincent*, *Lady Pirrie* and *Lyon Rose*. Whites—*Molly Sharman Crawford* and *Mrs. W. H. Stevens*. Blush and cream—*La Tosca*, *Viscountess Folkestone*, *Augustine Guinoisseau* and *British Queen*. A. P.

A GOOD GARDEN ROSE.

AMONG Roses of recent introduction, few are likely to give more satisfaction in the garden than *Arthur R. Goodwin*. Although it was only put into commerce in 1910, it now finds a home in a great many gardens, where its earliness and freedom of flowering rightly place it in the forefront of bedding Roses. The National Rose Society's official description of its colour is coppery orange, passing to salmon pink; but this scarcely does it justice, the salmon pink seldom materialising, the fully-opened flowers being more of a buff yellow. In the bud and half-opened stage they are very charming, and when full blown the petals do not drop for some days, a lasting character that is also found in that grand crimson Rose *Château de Clos Vougeot*. The accompanying illustration, from a photograph taken early in June, shows a bush that was planted last year, and at the time of writing, i.e., August 7, it is again flowering equally as freely. As will be seen, it makes a compact bush, and never seems to be affected by mildew.

A. B. ESSEX.

ARE UNWIELDY NAMES DETRIMENTAL TO ROSES?

This matter was brought rather prominently to my notice by the remark of a large grower, who said that the name of a certain Rose "absolutely kills the variety," also that he did not believe it would ever become popular under the circumstances. I am quite averse to a long, ungainly name, but I imagine if a Rose possesses real merit, its name will not prevent it being grown. I remember when *Frau Karl Druschki* came out there was a cry raised against its name, but it is now in almost every garden in the land, and familiarly known as *Frau Karl* or in the trade as *Druschki*.

I remember the introduction of a French Rose named *Fiançailles de la Princesse Stephanie et de l'Archiduc Rodolphe*. Of course, this was difficult, but if the Rose had any real merit it would still be grown to-day. I daresay to foreign ears *Mrs. Wakefield Christie Müller*

sounds just as bad as many of the German names of Roses do to us.

What I do protest against is dual names. We have now two *Geoffrey Henslows*, which must lead to confusion. I think, also, that we should protest against altering a name from that given by the raiser. The raiser of *Mme. Caroline Testout* would never think that his Rose would be known and listed as *Caroline Testout*, or *M. Joseph Hill* as *Joseph Hill*, and I do not see that we are warranted in so doing. The whole subject is one worthy of our highest authority, the National Rose Society, taking in hand and giving rules for our guidance; but in the matter of deleting the *Madame* and *Monsieur* they themselves have set a bad example. We want something definite to go upon. Are we to catalogue a Rose under the name as given it by its raiser, or are we justified in abbreviating it? Perhaps some of your readers will kindly give the benefit of their views. I hope I shall not be misunderstood. I am quite in agreement with the giving of short, euphonious names, and would welcome the rule most cordially; but I do not consider a bad name is sufficient excuse for driving, as it were, a good Rose from our lists, neither do I think it will have this result with all right-thinking individuals.

DANECROFT.

FLOWER GARDEN.

PRIMULA COCKBURNIANA HYBRIDS.

I AM much interested in your note on the above in *THE GARDEN* for June 28, page 324, and especially to that portion of it which contains the statement that, by rights, the name of the *P. pulverulenta* × *cockburniana* hybrid should be *P. Unique*, and the name *P. Lissadell Hybrid* should go. Your writer evidently assumes that the plants are identical; but is this really the case? I grow no fewer than four forms of the hybrid: (1) Veitch's *Unique*, (2) *P. Lissadell Hybrid*, (3) a hybrid I raised here, (4) a chance self-sown hybrid from the garden of Colonel the Hon. Frederick Shore of Thomastown. None of these forms is absolutely identical. Veitch's *Unique* seems to be almost intermediate between its parents; *P. Lissadell Hybrid* seems slightly nearer *P. pulverulenta*. *P. Unique* is possibly a shade brighter, but *P. Lissadell Hybrid* makes up for any deficiency in colour by an added strength of growth and constitution, no doubt acquired from its slight addition of *pulverulenta* blood. My own hybrid has much larger flowers, but they are rather washy in tone, and Colonel Shore's hybrid is by far the best I have seen, practically identical with *P. pulverulenta* in growth and constitution, while retaining the brightness of *P. Unique* and *P. Lissadell Hybrid*.

But putting these two latter forms aside and returning to *P. Unique* and *P. Lissadell Hybrid*, the plants I saw growing at Lissadell all possessed that extra vigour of growth and constitution so noticeable in the plants they sent to me, and in the many gardens where I have seen the hybrid growing, this stronger form is the most prevalent,

and one can but assume that the majority of the plants of this hybrid which are grown are really *P. Lissadell Hybrid* and not *P. Unique*. This conclusion is not so improbable as it seems when one considers all the circumstances. *P. Unique* was raised by Messrs. Veitch under conditions not particularly suitable for the raising of moisture-loving *Primulas*. The climatic conditions of that part of the South of England in which the nurseries are situated are against them. On the other hand, *P. Lissadell Hybrid* was raised in the West of Ireland under conditions of temperature and moisture almost ideal for *Primula* propagation; consequently, it increased very rapidly, and the growers, having a very large stock, were able to put it on the market at a price about thirty-three per cent. cheaper than *P. Unique*; and my theory is that nurserymen must have bought it up largely and sent it out as the higher-priced *P. Unique*. In no other way can I account for the preponderance of the stronger-growing form which obtains in most

well for the last three or four years, during which time the bed has been undisturbed. Like other garden Lilies, it is well adapted for growing in beds with peat-loving shrubs, such as *Azaleas* and *Rhododendrons*. This Lily attains a height of 3 feet or 4 feet. The flowers are white within the trumpet and of a brownish purple hue outside, making it a very desirable and attractive subject.

WORK AMONG THE DAHLIAS.

ALTHOUGH the Dahlia has good-sized, fleshy tubers, as a rule, few plants show signs of distress sooner in dry weather. The blooms suffer in proportion, some of them not fully developing when the roots of the plants are very dry—dry enough to cause the leaves to become flabby when the sun shines on them. Water must be given in sufficient quantity to maintain the soil in a moist state as deep as the roots go. Twice every week apply manure-water in a weak state, and the general appearance of the plants will be most satisfactory. On the

A BED OF LILIUM BROWNII, A BEAUTIFUL DWARF LILY FOR THE OUTDOOR GARDEN.

gardens. I see the difficulty in retaining two names for plants which are so very similar, but it seems rather hard lines on Lissadell, which has given us a plant of such excellent constitution, to absorb its hybrid absolutely. All I can suggest is that as we have a *Dianthus atrorubens* Carton variety, so at least let us have a *P. Unique Lissadell* variety.

Knappton, Abbey Leix. MURRAY HORNIBROOK

A BEAUTIFUL GARDEN LILY.

(LILIUM BROWNII)

ONE could hardly wish for a more glorious sight than that of a group of *Lilium Brownii* on a sunny July morning, when the flowers are at their best. It is strange that this fine Lily is so seldom seen, except perhaps in the greenhouse or conservatory. It is certainly worthy of extended cultivation as a garden flower, and by way of emphasising this fact it may be pointed out that the bed of this Lily illustrated on this page has flowered

younger shoots that bear buds the resultant flowers will be very neat and refined, and the supply of bloom will be maintained well into the autumn.

Earwigs.—These are a serious pest in some districts, and in few gardens more so than those in towns. More insect pests are found in town gardens than in country ones. The trapping of earwigs in moss and hay placed in empty flower-pots and between two dry boards placed on the ground at the foot of the walls and fences, and also under the plants, and the use of short lengths of *Beanstalks* are all useful methods of lessening the numbers of the enemy, but I am a firm believer in the employment of the fading Dahlia blooms for the same purpose. Take off the blooms and fix them between the stems of the plants about a foot above the ground, and more earwigs will be found in them every morning than in all the other traps. Shake out the insects, destroy them, and replace the blooms until too much faded to be of any use.

AVON.

COLOURED PLATE.

PLATE 1475.

FOUR GOOD DAFFODILS.

FOUR very pretty flowers are brought together in the coloured plate which is presented with this issue of THE GARDEN. Two of them are comparatively old, and two of them—the two varieties on the right-hand side—are new. I am unaware what the price of Chamois is likely to be, but none of the other three is so expensive as to be prohibitive if one yearly buys a few bulbs of a value of from ten to twenty shillings. St. Olaf was introduced to the public

centre (whatever name we give it) is $1\frac{1}{4}$ inches. I am most anxious to see its behaviour as a growing plant, and after I have wintered it and sprung it in my garden I will doubtless have something more to say about its behaviour there. I may be deceived, but I cannot help thinking, from its general appearance, that it will be a very good variety.

Chamois, as may be seen, is a flower of a different type. Instead of rounded, broadly overlapping perianth segments, we get them longer and more pointed, while the cup has a pronounced rosy salmon tone in its colour. As I can find no record in my notes about it, I cannot do better than quote *in extenso* the description which will appear in the list of Messrs. Barr and Son, who have acquired

Ibr., Acme, The Bride, Algernon Swinburne, Muriel, Chaucer, Virgil and Dresden. I used to think Horace red-eyed, but it is not so now. I am doubtful, too, if Virgil should be in the list. Red Emperor is one of those flowers which have been assigned a name of which "no fellow can understand" the why and the wherefore except on the principle of contrariety. It is not red and it is not an Emperor. If ever a flower can be said to have an orange eye, this one can. I describe it in my notes "pure orange flat cup." It is this pretty colouring which so much appeals to me, as getting away from the more usual red shades. The perianth is white and reflexing. A measurement taken at the same time that I made the above note says

A VIEW IN MR. HANBURY'S ROCK GARDEN AT BROCKHURST, EAST GRINSTEAD.

by its raiser, the Rev. G. H. Engleheart, at the Royal Horticultural Society's Daffodil Show of last spring. Few people, however, saw it on his stand, for it was very quickly bought by Messrs. Barr and Sons, who displayed it for the rest of the two days in their choice collection, where it more than held its own as an attractive and satisfying flower. Readers may remember that in my account of the show I recorded the high opinion that the raiser himself had formed of it. It gave him, he said, more pleasure than any other there. I at once fell a victim to its charms, and it was not very long before I secured a few for my own collection. The flower, as may be seen, belongs to the type of what in old-fashioned nomenclature might be styled an Engleheartii Leedsii—that is, it is a flat-cupped or saucer-crowned bloom with the pale buff colouring indicative of the group. The diameter of the perianth is $3\frac{1}{4}$ inches, and that of the flat corona, eye or

the stock from the raiser, Mr. Cave: "Leedsii variety—a very elegant and beautiful flower, measuring $3\frac{1}{4}$ inches across, perianth pure white and elegantly twisted. Crown open and fluted, shaded salmon on a white ground with a pale green centre. Height 13 inches."

Coming now to the two older varieties, we have in Dresden a good example of that not very large class of Poets, the all-red eyes. The perianth segments are round and overlapping, and the eye is very flat and very red. The whole is a good circular flower, useful either for showing or for cutting for vases, as the stem attains the respectable length of 16 inches to 18 inches. Two years ago, I find, I began to make a list of the varied eyes which are found among the Poets, and to assign the different varieties to one or another of the types. I was surprised to find how few could be said to be all red. The only ones I then put down as coming under this description were

$2\frac{1}{2}$ inches by 1 inch. It blooms about the same time as Occident.

JOSEPH JACOB.

OUR SECOND PRIZE ROCK GARDEN.**BROCKHURST, EAST GRINSTEAD.**

PORTIONS of the rock garden in process of construction at Brockhurst, East Grinstead, the residence of Frederick J. Hanbury, Esq., form the subject of these illustrations. Rock was discovered on the site about three years ago when planting Rhododendrons, and it was at once decided to commence a new rock garden in this part of the grounds. Begun on a small scale, the scope and design were soon altered when it was found that the stone increased both in quality

FOUR GOOD DAFFODILS.

1. Dresden. 2. St. Olaf. 3. Chamois. 4. Red Emperor.

ANOTHER VIEW IN THE NATURAL ROCK GARDEN AT BROCKHURST.

and quantity as the hillside was pierced. Fortunately, the quarry where the best stone was found was nearly at the top of the hill, and from it blocks of five tons and downwards were taken down the hill on rollers or a small trolley, and were used in the construction of the parts of the rock garden shown in the illustrations.

In order to utilise the quarry itself as a part of the scheme, a winding ravine has been cut through the solid rock to connect it with the lower portions. Here the cliffs are some thirty feet high, and the effect is enhanced by a high background of rock above the quarry, so that stone will be seen against the sky-line. A dripping-well is another feature in the quarry itself.

The mounds in the portion shown in the illustrations were formed by removing the top spit of the field, digging out paths, and utilising the poorer sandy soil to form the foundation of mounds. Much useful stone was also found near the surface. Owing to the winding nature of the paths, every aspect is provided for the plants. There are rocky pools and a bog garden by the main walk, which is an eighth of a mile long.

About the centre of the rock garden a beautiful cleft has been obtained by simply denuding the natural rock of the soil above, and on this portion a considerable collection of *Sempervivums* and *Saxifrages* has been planted. At the base of this portion, and where the rock dies into the ground, a moraine is now being constructed, with water flowing beneath.

The rock is a pure sandstone, in which there are large natural vents, and the surface of the stone in these vents is not only pleasing in its curves, but often beautifully stained with iron. No blasting was necessary for getting it out. The general

trend of the rock garden is towards the south-west, and the site selected is fortunate in being surrounded by Firs and other conifers and *Buchs*, the whole commanding a beautiful view towards Ashdown Forest.

THOMAS MATTHEWS.

Brockhurst, East Grinstead, Sussex.

THE GREENHOUSE.

ON SCENTED PELARGONIUMS.

SOME ten years ago, in a middle moment, I mounted a certain hobby, allured mainly by the fact of it

being of an almost forgotten breed. On that delightful moment I have ambled for many a happy hour through the quiet lanes of a country life. It has led me along the pleasant paths of many new friendships. It has also carried me more than once on an exciting chase, ending sometimes in a successful capture, sometimes in a blank day and bitter disappointment. But I never imagined when I started riding my hobby that I should be landed in front of this extremely big and alarming fence, viz., giving a lecture before the Royal Horticultural Society on the subject. However, I suppose the only thing to do is to screw up my courage, throw my heart over, and hope to surmount the obstacle without making too big an idiot of myself, while craving your kind indulgence for a very amateurish performance, for, alas! I am no scientist. Mr. Wilks has asked me to give you my experiences on scented *Pelargoniums*. That sounds rather a large order, for during ten years and more one goes through many and varied experiences. I think perhaps the best way to carry out his orders will

be to divide what I want to say into sections, and I will try to be concise: 1. History. 2. Collecting. 3. Classification. 4. Cultivation.

History.—You perhaps all know how *Pelargoniums* came to be introduced into England. I mentioned the facts, as far as I know them, in my article in the *Royal Horticultural Society's Journal*, Vol. XXXVII. But as probably few read it, forgive me if I briefly recapitulate them here.

Scented *Pelargoniums* seem to have been imported chiefly from Cape Colony, the native country of most of the species known to us. They came to

LARGE BOULDERS USED WITH FINE EFFECT AT BROCKHURST, EAST GRINSTEAD.

England, presumably in the case of the earliest introduced (1690) specimens, by way of Holland, the Dutch being then in possession of the Cape; in or after 1795, probably direct to this country, the English fleet having been sent out in that year to support the Dutch supremacy at the Cape. Constant intercourse went on from that date between the two countries, until in 1815 Cape Colony was finally ceded to England.

That, I think, will quite account for the following facts. From 1815, the date of the Cape annexation, all through the early years of the nineteenth century, there was a steady supply coming direct into England of rare and curious species of Pelargoniums and their near relatives—Campylias, Ciconiums, Dimacrias, Erodiums, Geraniums, Grenvilleas, Hoareas, Isopetalums, Jenkinsonias, Monsonias, Otidiats, Phymatanthus and Seymourias. But with all these off-shoots, if I may so call them,

a whole series of Geraniaceæ, the Hoareas, were named; and, finally, the Earl of Chester's at Melbury House, Dorset, which is not mentioned in Sweet's "Geraniaceæ," but a copy of the catalogue of which I possess, comprising 111 varieties, dated 1817. Now, of all those collections in houses of which I know something, not one survives at the present day, and I have no doubt that it is the same in other parts of England. Where have all those rare and valuable specimens gone? My theory is that they were ousted by the mid-Victorian craze for Zonal and fancy Pelargoniums, of the evolution of the latter of which I shall have something to say under the head of "Classification." My idea is that the existing survivors of the older and far more interesting Cape and scented Pelargoniums are those which lingered on undisturbed in out-of-the-way and old-fashioned gardens, such as Mr. Dorrien-Smith's at Tresco Abbey, Isles of

are thought essential for producing the finest hybrids." My own idea is that there are many more to be found in country places by those who keep their eyes open. Only last month I came across two beauties in my own village, after having, as I thought, explored every garden and window in the place. Still, up to the fifties there must have been people who were interested in their cultivation, for those years saw the invention of the Shrubland series—Shrubland Pet, Shrubland Rose, Shottisham Hero, and possibly my Lothario and Touchstone. They were the productions of the well-known horticulturist David Beaton, who was, I believe, gardener to Sir William Middleton, Shrublands, Ipswich, hence the name of the varieties. So much for the history. And let me sum up this section with this bit of advice: "Keep your eyes open wherever you go, especially when passing cottage windows."

2. Collecting.—The first step in starting a collection is to follow the classic advice of Mrs. Glass' cookery book, "First catch your hare." As to the way to accomplish this. All collectors are proverbially brazen, and I myself plead guilty to having been extremely—shall we say metallic?—in some of my doings. Harmless old ladies have been assailed on their own heartstones and blandished into selling treasured plants. Perfect strangers, who have for their sins possessed a coveted specimen, have been bombarded with begging letters. Kind friends have been badgered till they must have been sick of the sound of my name. And all have treated me with consideration and courtesy, with the exception of one old woman in a Belgian village, who drove me from her door with contumely, asking if I thought she was going, for the sake of my dirty silver, to rob "Le Bon Dieu" of a plant—and such a plant—which was destined to figure in the Corpus Christi Festival the following week. As I draw the line at committing sacrilege, even to get hold of a new specimen, I departed with my tail between my legs, and regret harrowing my soul. So perhaps my experience No. 2 may be summed up thus: "Don't stick at trifles, and

don't be shy of asking." For up till now it has been impossible to buy specimens from nursery gardeners; either they have not got them or those they have are named wrongly. The only chance hitherto has been the courtesy and charity of fellow-collectors, which I have always found to be unbounded, provided one asks politely and *personally*. I have reasons of my own for emphasising this last point.

(To be continued.)

[The article of which the foregoing is a portion is by Miss Troyte-Bullock, and is reprinted from the Royal Horticultural Society's Journal by kind permission of the Council. The illustration on this page represents some very large trained specimens of these old-fashioned, sweet-scented plants in front of Mr. Leopold de Rothschild's residence at Acton, where the head-gardener, Mr. James Hudson, V.M.H., grows them to perfection.—E.D.]

LARGE TRAINED PLANTS OF SCENTED PELARGONIUMS AT GUNNERSBURY HOUSE, ACTON.

of our subject, we have little to do, though one or two I shall have to mention later on. From 1820 onwards nurserymen and private collectors seem to have rivalled each other in procuring rare specimens and producing new and beautiful hybrids, until at last from these charming and elegant—I use the last adjective advisedly—plants were evolved the series we know as show or fancy Pelargoniums. If you look through Sweet's "Geraniaceæ," as I have been privileged to do lately in the Lindley Library, you will be astonished to notice the number of fine collections that existed in English country houses at the date of that standard book, viz., 1820-28. To mention a few in my part of the world only, the West Country. There was one at Longleat, the Marquis of Bath's; one at Haldon, the seat of the Palk family; another at Luscombe, Devon; a world-famous one at Stourhead, formed by the Wiltshire antiquary and scientist, Sir Richard Colt Hoare, after whom

Silly, the only place I know where the original collection is *in situ*—though I am told that Lady Scarborough's collection still flourishes in the original home of Pelargonium Scarborough Countess of Scarborough—or which, when exiled from the fashionable garden of the day, found a home under humbler roofs, often those of cottages. Another possible reason for the disappearance of many beautiful varieties may be that, being hybrids, they have just died out in the course of years, or reverted back to the original stock, as we see so many modern hybrids do. Still, one would think that cannot have happened to over three hundred varieties, which is the number, roughly speaking, of those of which I can so far find no trace. But even Sweet in 1824 says in "Geraniaceæ," Vol. III., page 299, *a propos* of *P. odoratissimum*, "It is now become rather scarce, as are those of the old original species, none of them being now much cultivated, except a few that

GARDENING FOR BEGINNERS.

HOW TO "TAKE" CHRYSANTHEMUM BUDS IN AUGUST AND SEPTEMBER.

THE cultivator of Chrysanthemums has a really busy time from the insertion of the cuttings to the development of the blooms. Each stage of growth presents its interesting features, but none is more absorbing than that of the development of the buds and flowers. For a period of about nine months an effort has been made by the cultivator to secure strong, well-matured stems and leaves. If the slightest mistake be made at bud-taking time, a whole flower or a plant may be lost.

How to Take Crown Buds.—The crown bud is one which is surrounded by shoots, and if the crown buds of late-flowering varieties show during the first half of the month of August, the flowers resulting will usually develop early in November at the same time as those of earlier-flowering varieties. If the cultivator fails to "take" the crown bud of the late varieties in August, the later-formed terminal buds will be useless for exhibition purposes. In the case of the incurved and also of the single-flowered varieties, very early-formed buds develop into coarse blooms, so that it will be advisable to pinch out the buds of these that form during the first half of August, and depend on those formed on later-grown shoots. Fig. A at No. 1 shows the stem of a shoot bearing a crown bud. Side shoots have already been removed from the axils of the leaves at No. 2, and it now remains for the cultivator to pinch out the shoots Nos. 3, 3, just when they are advanced enough to be quite clear of bud, stem and main leaf. No. 4 shows the crown bud. The process of "taking" should extend over about six days; each day one or two side shoots must be pinched off, then the bud will continue to grow and not be checked. Nos. 5, 6 and 7 show the gradual swelling of a healthy bud. It is not wise to remove side shoots too soon, nor is it

A SERIES OF CROWN BUDS. THE MANNER IN WHICH THEY SHOULD BE TAKEN IS DESCRIBED IN THE TEXT.

advisable to allow them to continue growing too long, else they will overpower the crown bud, leaving it stunted while they grow on. No. 8 shows side shoots left on the stem too long, and as a result the bud shrivels, as shown at No. 9. No. 10 shows the swelling stem, No. 11 the bud grown to its fullest extent, and No. 12 the same bud drying up while the main leaves increase in size quickly. Thus neglect in timely taking of the bud results in the loss of a bloom.

How to Take Buds of the Single-flowered and Terminals Generally.—Very early buds of

single-flowered Chrysanthemums develop into rather coarse blooms on short stems, with flower petals very short, too, as shown at No. 1 in Fig. B. Terminal buds and those taken late, in the case of the single-flowered varieties, develop into refined flowers, possessing long petals of a rich colour, as shown in No. 2. At No. 3 there are some terminal buds shown; the central one—the largest—No. 5, must be retained, and the surrounding ones, Nos. 6, 6, pinched off. Nos. 4 and 7, respectively, show the terminal buds swelling up freely. Terminal buds and those of the single-flowered varieties are usually large and flat.

Damaged Buds.—If the side buds in a cluster of terminals are torn away, bringing with them some of the bark of the main stem, as shown at No. 8, one side of the central bud will only half develop. If insect pests, especially earwigs, eat out the centre of the bud, as shown at No. 9, then the fully-developed bloom will contain a number of short petals. When the stem is eaten just below the bud, as shown at No. 10, the resultant flower will be uneven in form, one side being larger, with stronger petals, than the other. It is advisable to stop the feeding of the plants for about a week while engaged in "taking" the buds.

PLACING WINDOW PLANTS IN RAIN.

ONE frequently sees Ferns, Aspidistras and Palms, also other kinds of plants, put outside during rain showers so that the leaves may be washed clean. It is a very good plan to treat the plants in this way when they are placed in a shaded position. The mistake generally made is to expose the plants to sudden bursts of strong sunshine as well as to the rain, with the result that many leaves which have never before been exposed to the sun's rays get badly scalded. There would be no risk if the plants were taken indoors again before the sun shone, or if they were put in a position not exposed to the sunshine. G. G.

MAKING THE MOST OF TERMINAL AND DAMAGED BUDS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

General Work.—Owing to stress of work during the early summer months, the outlying parts of the pleasure grounds are sometimes apt to get a little neglected, but every effort should be made to keep up with the work. Practically the whole of the evergreen shrubs, such as Hollies and Laurels, will now have dropped their leaves, and a good raking through all the shrubberies should make them tidy till the more general fall of the leaves from the deciduous trees.

Pruning.—Though I am not in favour of late-summer or autumn pruning, some of the more irregular-growing shoots may be pruned to keep the plants in a shapely condition; but nothing like a general cutting should be given, or the subjects so treated will look stiff and unsightly during the whole of the winter.

The Flower Garden.

Propagating Zonal Pelargoniums.—The work of propagating Zonal Pelargoniums should now be commenced in earnest, and as the plants have made very good growth this season, there should be no dearth of good cuttings. To preserve the beds in good condition, the cuttings should be taken off carefully, and it may be advisable to go over the beds twice at intervals of a fortnight, rather than to take off too many cuttings at once. Whether they are to be propagated in pots or boxes must be decided by the individual, taking into consideration the accommodation for them during the winter months. Pots, I think, are preferable, and a greater percentage of good plants results from this method. Paul Crampel, being a somewhat strong grower, is apt to become drawn if several are rooted in a pot or in boxes, so I prefer to strike this variety singly in small pots.

The Scented Geranium Lady Plymouth is a first-class bedder, but to be really successful with its propagation it requires a little heat and moisture, which for most varieties is quite unnecessary, though it is wise to stand the cuttings in frames or in some such position where they may be covered in the event of heavy or continued rains.

Melianthus major is a fine glaucous-leaved plant for summer bedding, and, to obtain good specimens for next season, seed may be sown at any time now. After sowing, place in a warm frame, and pot off singly when large enough to handle.

Eucalyptus sown now also makes nice plants from 3 feet to 4 feet high for next season. Treat as advised for *Melianthus*, and in neither case is much heat necessary during the winter months.

Plants Under Glass.

Pelargoniums for Winter Blooming.—These are now thoroughly well established in their flowering pots, and though they do not require much in the way of manure, a little soot-water will just keep them active and the foliage a good colour. If bloom is required in October, the shoots should not be stopped after about this date, though it is advisable to go over the plants now and stop the strongest of the shoots.

Regal, Show and Fancy Pelargoniums that have been partially dried off may be turned over on to their sides to complete the drying off, ready for pruning the first or second week in September.

Celosias.—The late-flowering batch will now be producing their plumes. If in moderately small pots, feed them regularly, reducing the amount of atmospheric moisture as the plumes develop, when they should keep in good condition for a considerable period.

The Kitchen Garden.

Winter Onions.—During the next few days the winter Onions should be sown, and where the soil is heavy it is wise to lighten it as much as possible with wood-ashes, leaf-soil and light manure. Needless to say, it should be well prepared by trenching and manuring, breaking it up as finely as possible before sowing. For early work *White Leviathan* is a good variety, while for later crops *Ailsa Craig*, *Giant Rocca* and *Cranston's Excelsior* are all excellent varieties.

Coleworts and Other Greens.—The ground thus cleared may be levelled over and planted

with Coleworts, late Savoy and winter Cabbages, as one generally finds that they do not get too much winter greenstuff, especially where the kitchen garden space is limited.

Fruits Under Glass.

Summer-Pruning Peaches.—Early and some of the mid-season Peach trees will now be better for having most of the old fruiting wood taken out. This must not be done carelessly or by an inexperienced person, as when taking this wood out due consideration must be given to extending the branches where the trees are not filling all the available space. Where the trees are full grown, the summer pruning is a much easier matter, and nearly all the fruiting wood may be taken out, thus giving much more light and air to the fruiting wood of next year. Very early forced trees are not benefited by too much sunlight, and a little shading on the glass during very hot periods may be more of an advantage than otherwise. I have noted in a narrow Peach-house, where Chrysanthemums are placed close to them in September, thus robbing them somewhat of light, that the flowers have been much more abundant and stronger the following spring.

Hardy Fruit.

Wasps.—Though these are not so plentiful as in some seasons, steps should be taken to destroy all the nests in the neighbourhood of the garden. In addition to this it is advisable to partly fill bottles or gallops with stale beer, treacle, &c., and hang them on the walls or trees where fruit is ripening, thus getting rid of many of them before they do much damage to the fruit.

Preparation of the Ground for Strawberries.—This should be done as early as possible, so as to allow the soil to consolidate a little before planting. If a piece of ground that has been well trenched and manured for Peas is chosen, it should not be necessary to more than single dig it, first giving it a good dressing of wood-ashes, bone-meal and soot. Heavy ground should be broken up as finely as possible during the operation, so as to facilitate planting.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey

FOR NORTHERN GARDENS.

The Flower Garden.

Propagating Geraniums or Pelargoniums.—A start should now be made with the propagation of bedding Geraniums. With the exception of variegated-leaved sorts, which have almost gone out of cultivation, they should be placed in boxes of sandy soil and stood in a sunny position in the open air. In selecting the cuttings, give preference to those which have been well ripened by exposure to air and light. Give one good watering to settle the soil about the cuttings, after which keep them rather dry.

Colchicums.—This is the best time to plant these beautiful autumn flowers. The following are all worthy of a place: *C. autumnale flore pleno alba*, *C. flore pleno roseo*, *C. Bornmülleri*, *C. giganteum* and *C. speciosum*. *C. autumnale* (Meadow Saffron) is suitable for planting in quantity about the shrubberies or the wild garden.

Iceland Poppies.—If left to themselves, these dainty flowers reproduce plentifully. The careful cultivator, however, selects his seed and sows it about this period in a box, pricking off the seedlings in due course. By this system the orange and newer art shades will be increased, also the doubles or semi-doubles, some of which are very attractive.

The Wall Garden.

Watering must still have attention, especially if it is a double-faced wall. The water should, however, be applied through a fine rose or spray to prevent it from running.

Tidying Up.—The bulk of the subjects here will now be past their flowering period, so the whole should be overhauled and all decayed flower-stems cut away.

The Pleasure Grounds.

Lawns.—If coarse weeds such as Plantains reassert themselves, they should be promptly cut

out with an old knife. If drought occurs, watering must still be resorted to, and happy are those who possess one or two standpipes, with a good length of hose and an abundant supply of water.

Woodlands.—In places of any size there is generally some amount of woodland beyond the lawn where the scythe is applied two or three times a year. If this is gone over now, it will not give further trouble this season, and the benefit of the operation will be fully appreciated when leaf-raking commences.

Plants Under Glass.

Sowing Annals.—Sowings of *Schizanthus* and *Clarkias* should now be made for a spring display. Sow thinly in pans or boxes in a cold frame. Water before sowing, and afterwards cover the receptacle with a pane of glass or a sheet of paper to conserve the moisture till germination takes place. Till then shade from bright sunshine, after which gradually more to full light. *Clarkia elegans* freely and *C. c.* *Salmon Queen* both deserve attention.

Hydrangeas.—Many growers propagate in July. I prefer August, as by this time the shoots have ripened better and one is more certain of securing the latent flower-bud, without which a season will be lost. We root them in 2-inch pots of sandy soil stood in a big, shallow packing-case, covered with sheets of glass, in a Melon-house from which the plants have been removed. Maintain a fairly brisk temperature and keep close and shaded till roots are formed. If hortensis takes some beating when well grown, but some of the newer varieties should certainly be grown. There are now a number of these, but I can confidently recommend *Radiant*, *Mousseline*, *Mme. E. Moulière* and *La Lorraine*.

Malmaison Carnations.—As soon as the layers begin to show signs of growth, they should be severed from the parent plant and potted up into 4-inch pots. Good substantial loam with a little sand and wood-ashes will be found a suitable compost at this stage. Sprinkle a little soot over the rough material covering the drainage.

Fruits Under Glass.

Late Peaches.—See that these are provided with a net to catch the fruits, which are so easily damaged. In pulling these, the fruits should be surrounded by the fingers and thumb, and unless they yield to the slightest wrench, they are not fully ripe.

Orchard-House Fruits.—Apples and Pears ripening their fruits should have these encased in small nets to prevent damage by falling. Remove any leaves which obstruct the sun's rays from the fruits. The trees must not be allowed to become dry at the roots, and pot trees will still require close attention, as water may sometimes have to be applied twice daily.

The Hardy Fruit Garden.

Matting Currants.—Where it is desired to maintain a supply of these as long as possible, part of the crop on a north wall should be matted to exclude the light. By this means the crop may be maintained in good condition for several weeks yet.

Planting Strawberries.—Strawberries may still be planted, but unless the work is carried through during the ensuing week, there is no hope of the plants yielding a crop next season.

The Vegetable Garden.

Vegetable Marrows.—The shoots require judicious thinning and stopping to concentrate the energies of the plants on the fruits to be retained. If there is a superabundance of fruits, the surplus can be used as a preserve, with the addition of some Apples to give them piquancy.

Kidney Beans.—At this period there is often a glut of these. Where this is so, the surplus can be preserved between layers of salt in a stone jar, where they will keep for quite six weeks. They can, of course, be preserved for an indefinite period by the modern bottling system.

Pickling Onions should now be harvested, and none but small, well-ripened bulbs should be retained for that purpose.

Onions for general use, if inclined to grow too persistently, should be gone over and the foliage pressed down by means of an empty, flat-bottomed vegetable basket.

CHARLES COMFORT
Broomfield Gardens, Davidson's Mains, Midlothian.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, and cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

CARNATIONS GOING WRONG (Ifales).—The plants have been kept in too moist an atmosphere. Carnations succeed best when the atmosphere is kept dry about them and the soil has a sufficient degree of moisture. Yes; we think you will find a weak solution of sulphate of potash useful for use on your pale-leaved Carnations (about one ounce to two gallons of water, used once a week for a time). Water the Roses with a weak solution of sulphate of iron—about one ounce to one gallon of water. This will probably restore their green colour.

PROPAGATING ANGHUSA (M. A. B.)—Division of the root-stock in early spring and root propagation in winter-time are the only methods of increasing particular varieties of the above-named plant. The latter consists of digging up the plant, dividing it of some of its roots, cutting them into inch-long lengths and inserting them in sandy soil in boxes or pots, leaving the top of the cutting just visible above the soil. You should obtain "The Hardy Flower Book," by E. H. Jenkins, price 2s. 6d., post free, from this office, wherein this and other methods of propagation are treated fully.

INULA GLANDULOSA AND COLUMBINES (Northold, R. B. A.)—The Inulas may be increased by division in March or April, by seeds sown soon after ripening, and by root cuttings during winter. The two former usually suffice for all ordinary purposes. *Aquilegia chrysantha* is a tall-growing, yellow-flowered species, and one of the most graceful of early summer-flowering herbaceous plants. There are, however, hybrid strains between this and the other species which are also highly ornamental and may be freely raised from seeds. The popular name *Columbine* applies to the whole race.

TREES AND SHRUBS.

BOX EDGING TO CUT (T. F. H.)—Now is a good time to cut Box edging. There will then be time for short new growth to be made before winter. This will appear neat and bright all the winter. Do not cut too low, or the edging will be made brown and unsightly—only an inch, more or less, to make it appear even and straight.

WISTARIA LEAVES MUTILATED (K. A. P.)—The Wistaria leaves appear to have been eaten by the leaf-cutting bee. This bee removes circular pieces from the leaves of various plants for the purpose of making its nest. Spraying the plant with arsenate of lead would, no doubt, be an aid in preventing its attacks; but the bees, it should be remembered, are quite useful insects on the whole, and unless the damage done is really serious, it would be well to avoid killing them.

TREE PÆONIES (S. W.)—We advise you now, or in the September ensuing, to lift the plants and give them a sheltered westerly position. In this the ill-effects of spring frosts—about the only drawback to a good flowering that the plants, once they are established, suffer from—would be less felt, the sun reaching the plants too late in the day. In the easterly position you now have, the sun is upon them early; hence the trouble. Prepare the new position well by using sand and old cow-manure to a depth of 24 feet, and let the drainage be also good. The Tree Pæony, like the herbaceous sorts, does not

like frequent disturbance. Take care, too, in the replanting that the plants are buried fairly deeply, so as to get them upon their own roots as early as possible. Usually these Pæonies are grafted, and if not buried below the union between stock and scion, only an embedded root action is likely to ensue.

ROSE GARDEN.

CLIMBING ROSES (A. H.)—Liberal applications of liquid cow-manure are very beneficial to Rambler Roses at this season of the year when making their growth. Alternate this with nitrate of potash and phosphate of potash in the proportion of 1oz. to a gallon of water. Is your cable a wire one? If so, this has a good deal to do with the Roses not making longer shoots. The wire is extremely cold in winter, and the wind blowing the shoots against the wire chafes the bark. Can you enclose the cable wire in large Bamboo rods, or fasten two or three small thin Bamboo rods round it?

ROSE EARL OF DUFFERIN (Lady Franklin)—The season has been adverse to the development of this Rose. It is so very double that, unless we have warm weather and absence of rain, the buds cannot unfold their petals.

judge, one who knows his business, will recognise floral art when both the receptacles and the flowers are set up in simple fashion. Some judges foolishly think an epergne is an indispensable stand for the centre of the table; we think otherwise. A dainty dish or bowl of clear glass for the centre, with two small vases, one on either side of this, and four corner glasses or small bowls, make a charming decoration. Do not use too many flowers; let each flower and piece of foliage speak for itself; and avoid rotundity of outline in the arrangement of the flowers. We have judged many dinner-table decorations, and the best, prettiest and most artistic have been those arranged on the simplest possible lines. In a capital competition a few days ago we awarded first prize to a table decoration of one variety of *Violas*, both flowers and foliage being used most advantageously. The idea was simple in its conception and beautifully artistic. You should procure Roses of one colour, or, better, of one variety, Shirley Poppies, *Violas*, Carnations, Sweet Peas, the different forms of the Sweet Sultans, *Coropsis*—in fact, an almost endless list of subjects. Remember, in selecting colours, to use only those that look well under artificial light, for all dinner-table decorations are wanted for evening use. Therefore avoid blue, mauve and kindred colours. The hedgerow will often provide you with lovely foliage to associate with subjects having but spare foliage.

NAMES OF PLANTS. (Mrs. Dimlen.)

- 1. *Oenothera speciosa*; 2. *Erigeron glaucus*; 3. *Campanula carpatica*; 4. *C. portenschlagiana*; 5. *C. pusilla alba*.
- L. Baccon*—*Omphalodes luteifolia* (Venus' Navel-wort).—*J. Midgley*.
- Alstromeria aurantiaca*.—*M. E. B.*
- Campanula carpatica* (broad leaf); *C. luteifolia* (narrow leaf); *Sagina procumbens*; *Helichrysum speciosum*, cannot name without flowers.—*J. P. Sasse*.
- 1. *Vitis speciosa*, too scrappy for identification; 2. *Stachys lanata*; 3. *Pteris cretica albobindata*; 4. *P. c. cristata*; 5. too scrappy for identification; 6. *P. tremula*; 7. *P. serrulata cristata*.
- Alice Gill*. 1. *Impatiens Royletii*; 2. *Sedum Sieboldii*; 3. *Cerastium tomentosum*.—*J. Hogg*.
- Roses: 1. *Bouquet d'Or*; 2. *Jubus Margottin*.—*H. S., Howick*.
- Rubus speciosus*, cannot name without flowers; 2. *Thalictrum angustifolium* (Meadow Rue); 3. *Gentiana macrophylla*; 4. *Gentiana asclepiacea* (Willow-leaved Gentian); 5. *Epilobium Dodonaei*; 6. *Mertensia sibirica*; 7. *Helianthus autumnalis* variety; 8. *Lysimachia vulgaris* (Yellow Loosestrife); 9. *Lychnis diuca flore pleno*; 10. *Valeriana Plin.*; 11. *Liastropicta*; 12. *Allium sphaerocephalum*; 13. *Astrantia major*; 14. *Spiraea Ulmaria* (Meadow Sweet); 15. *Erigeron speciosus*; 16. *Crepis luteiflora*.—*T. C. A., Sasse*.
- Erica cinerea*.—*H. N. A.*
- Rudbeckia speciosa*; 8. *Geranium pratense flore pleno*; 9. *Geranium Endressii*; 10. *Linaria lparitaria*.—*N. W., Alchurch*.
- Lilium testaceum*.—*R. B.*
- Primula vulgaris* (Self Head). The only way to get rid of this plant from the lawn is to hand-weed it. Lawn sand will help. The leaf sent is not sufficient for identification. —*Skene*: 1 and 2. *Veronica longifolia* varieties; 3. *V. l. rosea*; 4. *Centaurea atropurpurea*; 5. *Fuchsia Riccartonii*; 6. *Achillea* species, specimen too scrappy to identify; 7. *Stachys Betonica*; 8. *Erigeron philadelphicus*; 9. *Sedum album*; 10. *S. ripense* variety. We fail to recognise the Roses. Can you send better blooms? The *Verlasium* is decidedly interesting. By all means grow both forms; one is a sport of the other.

SUTTON'S NEW SUNFLOWER. THE PREDOMINANT COLOUR IS CRIMSON AND BROWN.

Doubtless it would be a great success if planted against a south wall or in a south border at the foot of a wall. If grown in a border its growth should be staked, as it possesses a sort of semi-climbing nature. It is a Rose we do not recommend for the garden, its chief merit being an exhibitor's Rose only, and even for this purpose very uncertain. We advise you to discard the variety, and plant instead W. E. Lippatt, or, better still, George Jackson, varieties much superior, the latter especially.

MISCELLANEOUS.

TABLE DECORATION FOR SHOW (Mary S.)—You ask what points you should observe in decorating a dinner-table, 6 feet by 3 feet, for a show, and also what are the best flowers. In reply, we would suggest simplicity in design and character as essential factors to success. All too frequently dinner-table decorations at shows are too ornate and excessively overdone. Much depends upon the person or persons who judge the exhibits. Many so-called judges are quite incompetent to judge. A good

A REMARKABLE NEW SUNFLOWER.

The accompanying illustration is of Messrs. Sutton and Son's new Sunflower, which was referred to in our issue for last week. It is a very striking flower, with a broad band of chestnut red round the base of the yellow petals, and is the result of a cross made between *Helianthus annuus* (the common annual yellow Sunflower) and *H. luteiflorus* (the common wild Sunflower of North America) by Professor Cokerell of Boulder University, Colorado, who handed over his stock to Messrs. Sutton for development, and they are this year offering seeds for the first time. There has been no previous record of this colour in the popular *H. annuus*, which is such a well-known and favourite annual in English gardens.

SOCIETIES.

HESTON HORTICULTURAL SOCIETY.

THE seventh annual exhibition of the above society was held in the Heston Schools, Middlesex, on August 6. Heston is situated in the midst of market-gardens, so that it was not surprising to find vegetables well represented. The quality of the produce was higher than that of previous years. Autumn-sown Onions were remarkably fine, while Brassicas and root crops, particularly Potatoes, were shown in capital form, despite an unfavourable season.

The President's Challenge Cup for the most meritorious exhibit in its class was won by Mr. G. Little for three dishes of Potatoes. The varieties shown were Duke of York, Lincoln Early Red and British Queen, the tubers being of perfect shape and uniform in size.

One of the chief features of the show was a gold medal collection of Sweet Peas, shown by Mr. H. D. Tixwell, Greenford, Middlesex. Among the best of the varieties staged were Melba, True Lavender, R. F. Felton, Hercules and Mrs. C. W. Broadmore.

Messrs. Cragg, Harrison and Cragg, Mervale Nurseries, Heston, were awarded a gold medal for a group of flowering and foliage plants, including a first-rate collection of Perpetual-flowering Carnations; also a silver medal for Peaches.

A gold medal was awarded to the Earl of Jersey, Osterley Park, for a collection of foliage plants, chiefly highly-coloured Crotons and Dracaenas, that collected great credit upon Mr. A. J. Hawkes, the able head-gardener.

Messrs. Spooner and Sons, Hounslow, were awarded a silver medal for an extensive collection of Roses, in which the leading varieties in cultivation were displayed.

As previously mentioned, vegetables formed an important feature of this exhibition, the collections, both by amateurs and market-growers, being worthy of the highest praise, notably the one staged in a masterly way by Messrs. W. J. Lofdon and Son of Heston.

The Stephens' Cup for four dishes of cooked Potatoes was this year won outright by Mr. Hawkes, in keen competition.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE usual monthly meeting of the Scottish Horticultural Association was held in the hall, 5, St. Andrew Square, Edinburgh, on August 5. There was a good attendance, presided over by the president, Mr. David King, Osborne Nurseries. The exhibits comprised *Dianthus cæcæum*, *L. Himalajum magnifolium*, *L. chalcidifolium* and *L. chalcidifolium maculatum*, with *Stenandrium robustum*, the Mountain Leather Flower, from Messrs. Dicksons and Co., Edinburgh. Messrs. John Downie, Edinburgh, also exhibited *A-Gill's Pink Pearl*. The paper for the evening was given by Mr. John Highgate, gardener to the Marquis of Londonderry at Hopscoun Hill, etc. The subject was of special interest to amateurs as well as to gardeners, it being "Villa Gardening from the Professional Gardener's Standpoint." It showed that Mr. Highgate had studied his subject thoroughly and that he had a perfect grasp of the principles and practice which should dominate the arrangement and planning of the villa garden. Mr. Highgate went thoroughly into it, dealing with the lawn and its treatment, and trees and shrubs (in the course of this part condemning the use of such large trees as the Lime, the Elm, and such-like). The usefulness of climbing and other shrubs was pointed out; the value of holding an earlier flower ring; plants was also dealt with, and prominence given to the most useful plants for the small garden. A useful note was the portion relating to fruit trees; and growing Apples, Pears, &c., on cordons was suggested in view of the lowness of the walls generally built in connection with villa gardens. Mr. Highgate received a hearty vote of thanks.

SHOW OF SWEET PEAS AT DUMFRIES.

IN connection with the annual show of the Dumfries Agricultural Society on August 5, a capital show of Sweet Peas and a few other subjects was held. A cup and cash prize offered for twelve varieties of Sweet Peas brought out excellent competition and magnificent flowers. Mr. J. McGill, Kirkcubbin Gardens, was first; second, Mr. C. Murray, Cowhill Tower Gardens; third, Mr. R. A. Grigor, Dalswinton Gardens; fourth, Mr. J. McGill; v.h.c., Mr. F. Carmichael, Craigholm Gardens. In the amateurs' class for six varieties the prize-winners in order of merit were Mr. G. L. Mollat, Mayfield, Lockerbie, and Mr. J. Crosbie, Dalswinton Village. In the open classes for sweet Peas, for six varieties, the winners were: First, Mr. F. France, Kirkcubbin Gardens; second, Mr. J. McGill; third, Mr. C. Murray.

FIFE AND KINROSS ROSE, PANSY, VIOLA AND SWEET PEA SOCIETY.

THE annual show of the above society was held on July 26 in the New Hall, Cupar, and was the best display yet made by the members, who have every reason to be pleased with their latest efforts. The principal winners in the Rose section were Dr. Bowman, Messrs. James Anderson, L. Black, C. Lindsay, George Thompson and Thomas Seath. In the Pansy and Viola classes the successful growers were Messrs. Robert Rutherford, J. B. Bignar, Charles Gray, John Hill, Daniel McCreghan and Jane Campbell. Sweet Peas were an outstanding feature and Mr. F. Christie was the leading exhibitor. Other winners in this section were Messrs. J. Anderson, James Honeyman, John Hill and Charles Richardson. Mr. L. Black was the leading grower of herbaceous flowers. Other winners of the mixed classes were Messrs. Andrew Hill, J. Anderson, J. Hill and T. Christie. A very

interesting exhibit was put forward for the opinion of the judges; this was six plants of *Antirrhinum*. Instead of the flowering spikes, however, it was the silvery foliage of the plants which came in for the attention of all the visitors, and this exhibit justly deserved the certificate of merit awarded. Splendid exhibits of Roses were staged by Messrs. James McAra, Rose Growers, Crieff; and Messrs. James Fairley and Co., Rose Gardens, Carnegy-hill, Fife.

CAMBRIDGESHIRE MAMMOTH SHOW.

THE 1913 Mammoth Show of the above society, which was held on Monday, August 4 (August Bank Holiday), stands out as the finest exhibition during the decade of its existence. From every point of view, except weather, the show was brilliant. There were 1,100 entries, being 200 more than last year, and, considering the trying conditions, the quality of the exhibits was exceptionally high. The open competitions included exhibitors from Peterborough, Bury St. Edmunds, St. Neots, St. Ives and Middenhall. Pot plants were good, Miss Smith, Cambridge (gardener, Mr. F. Allen), was one of the principal winners, being first for Ferns, Puchsias, Coleus and Zonal Pelargoniums, all of which were exceptionally good. For specimen plants, stove and greenhouse, P. L. Hudson, Esq., Pampisford Hall (gardener, Mr. Kirkpatrick), showed some exceptionally fine plants. For a group of tuberous-rooted Begonias, P. J. Hall, Esq., was first, Miss Smith being second. Groups of plants were poorly represented, which was a great pity, as such a class greatly improves the appearance of any show. P. L. Hudson, Esq., was first with a beautiful well-arranged group, consisting of Palms, Ferns, Læcarous, *Clerodendron fallax*, *Begonias*, *Caladiums* and *Crotons*. The exhibition of cut flowers was remarkably good. The herbaceous Phloxes were the chief feature, these being magnificent. Mr. C. Bright, Cambridge, was first with splendid groups 12 feet by 3 feet and 6 feet by 3 feet, both collections consisting of well-grown flowers. Pentstemons and *Antirrhinum* were well shown by Miss Smith, who was first for both. Stocks, Sweet Peas and Roses were also good, Mr. C. Bright, Mr. P. Hawkes and Mr. J. C. Palmer being first in each class respectively, while other classes were equally as good. Perfect in detail and glorious in the mass were the exhibits of Roses, not for competition, shown by Messrs. Pine of Royston and Messrs. J. Burrell and Co. of Cambridge, and attracted a good deal of attention. Great credit is due to Mr. W. Stearn for the capable way he discharged the duties of hon. secretary of the horticultural section, and the hon. secretaries of the other section are deserving of equal praise.

ROYAL HORTICULTURAL SOCIETY

THE usual fortnightly meeting of the above society was held at Vincent Square, Westminster, on Tuesday last. In the midst of the holiday season it is not surprising to note that the hall was far less crowded than usual. Nevertheless, there were some fine exhibits, notably of hardy flowers, gladioli were shown by various exhibitors, while Delphiniums, Phloxes and the old-world Hollyhocks each contributed to the brightness of the floral display.

FRUIT AND VEGETABLE COMMITTEE.

Present: George Bunyard, Esq. (chairman), and Messrs. W. Bates, W. E. Humphreys, W. Pope, J. G. Weston, A. R. Allan, J. Willard, Owen Thomas, C. G. A. Nix, A. H. Pearson, J. Jacques, J. Davis, E. Beckett and A. Grillo.

Messrs. James Veitch and Sons, Limited, Chelsea were awarded a silver-gilt Kitchin medal for a collection of fruit trees in pots, of high quality and staged in the manner we have learnt to associate with this firm. The Peaches were remarkably well cropped, notably Sea Eagle and Klaus's Kent. Pears Souvenir du Congrès and Triomphe de Vicome, and a variety of Plums and Apples were shown, also a new Black-berry-Raspberry hybrid known as the Veitch Berry, with a decided Black-berry flavour and of exceptional size.

ORCHID COMMITTEE.

Present: J. G. Fowler, Esq. (chairman), Sir Harry J. Veitch, and Messrs. James O'Brien, Gurney Wilson, E. J. Haubury, W. H. Blatcher, G. Hunter, A. Dye, J. Charlesworth, A. McBean, W. H. White, S. W. Flory, W. Bolton, de B. Crawshaw and R. A. Rolfe.

There were only four groups of Orchids to claim awards. Mr. E. H. Davidson, Orchard Dene, Twyford, received a silver Flora medal, while silver Bankstan medals were granted to Mr. H. T. Pitt, Messrs. Charlesworth and Co., Hayward's Heath, and Messrs. J. and A. McBean, Cooksbridge.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. C. T. Drury, E. A. Bowles, T. Stevenson, G. Keuthe, J. W. Barr, R. Hooper-Peterson, J. W. Moorman, C. R. Fielder, J. F. McLeod, C. Blok, W. Bam, William H. Morfer, J. T. Bennett-Poe, A. Turner, Charles E. Pearson, W. P. Thomson, E. H. Jenkins, H. J. Jones, G. Paul, B. Crisp and J. Green.

Mr. M. Priehard, Christchurch, Hants, had a particularly good lot of the best herbaceous plants. Crimms, Montbrettes, Gladioli, Delphiniums, Phloxes and other showy things of the Phloxes, Iris of the blue-flowered set was one of the most striking, while M. A. Bichner, palest white, was also good. Selma, pink, with crimson eye, was also distinct. Gladioli generally were very fine, though to our thinking the most charming of them all were the hybrids of *G. pinnatifidus*, which have the attributes of grace and artistic beauty combined. Crimms,

both white and rose coloured, were very imposing, while *Coriaria japonica* was perhaps one of the most interesting plants in the group.

Mr. L. R. Russell, Richmond, displayed a table of hardy Puchsias in pots, in some dozen or so of the best sorts, together with *Ceanothus* and the best of the hardy Vines, as Vitis Cogneticæ, henryana and others. *Dimorphotheca mandshuricus argenteo variegata* was also well represented, a similar remark applying to the pretty coral-berried Nertera, which we have never seen better fruited.

Messrs. Dabbie and Co., Edinburgh, had a remarkable display of *Sedibosa atropurpurea* and its varieties, which are now as numerous as they are beautiful. The shades of mauve from palest to deepest appealed to us most strongly as lending themselves to decoration of the most artistic temperament. The *Collarette* Dahlias were particularly fine, Cimbras, Frogmore, McTeor, Queen Jess (orange and red), Yellow Queen and Prince de Venos (crimson and white inner borders) being of the best.

Messrs. William Wells, Limited, Mersham, staged some excellent Phloxes in their cut state in bold vases, Derviche (blue), Elizabeth Campbell (pink), King Edward (crimson), Iris (perhaps the finest blue), Richard Strauss (violet), Le Maholi (deep Parma Violet shade) and Arthur Lane (very fine pink) were among the best.

Messrs. James Veitch and Sons, Sadron Walden, staged Hollyhocks, both in the natural spike as grown and on boards in the cut state, in yellow white, crimson pink, coral and other shades.

Messrs. A. H. Cole, Limited, Swanley, exhibited a capital collection of Zonal Pelargoniums in some thirty or more leading commercial varieties. Crimson Crampel, Jan Macaren, Maxime Kovalevsky, Barbara Hope (a fine salmon), Venus (palest white) and Sir R. Ball (crimson-sealed) were among the best. Glorindas and an excellent strain of Pentstemons were also displayed.

Messrs. T. S. Ware, Limited, Feltham, filled a table with the showier herbaceous plants. Phloxes, Erigerons, *Azaranthus umbellatus* silius, Delphiniums and Galatheids, *Salsola nemorosa virgata* was particularly good and showy, as were also white and coloured Crimms and *Campanula grandiflora*.

Messrs. William Cutbush and Sons, Highgate, N., displayed a miscellaneous table of stove and greenhouse plants. *Caladiums*, *Dracaenas*, *Lilium auratum*, *L. longiflorum* in variety and *Begonia* President Carnot, *Dracaena Victoria* and *Cobus Carlota* (a finely-coloured variety) were both handsomely displayed in bold groups.

Messrs. H. B. May and Sons, Edmonton, displayed greenhouse Ferns in excellent condition, staging groups of *Adiantum farleyense*, *gloriosum*, *Davallia tenuifolia*, *Verbekei*, *Adiantum petivianum*, *Polypodium Mayi* and *Nephrolepis exaltata stipitata*. *Adiantum Foulkneri* is one of the most delicate and pleasing of the Maidenhair Ferns, and was well represented.

A small plant of *Saxifraga floribunda* in flower was shown by Mr. E. Crisp on behalf of Mr. A. W. Chaplin, Great Arwell, near Ware. It is a rare and interesting species, seldom seen in flower away from its native habitat.

Some excellent herbaceous Phloxes were shown by Mr. W. Wilkinson, Edmonton, Bishop's Stortford, but we did not notice any novelty of outstanding merit among them.

Mr. Charles Bick, Warren Nurseries, Hayes, exhibited a handsome vase of the deep apricot-coloured Carnation Mrs. Wharton. The variety earned an award of merit last year.

Mr. A. Worsley, Epsworth, exhibited the drooping, blue-flowered *Asperanthus Wellfleet*, which is very beautiful and distinct.

Mr. Angus Perry, Enfield, exhibited effective masses of Delphiniums and Adolles, the hybrids of *D. belladonna* making quite a feature. Of these we noted *D. semi-plena*, *D. Mrs. Brunton*, *D. Postman*, *D. Langmarie* and *D. Mrs. Thompson*, representing deep and light shades of blue. *Achillea Perry's White* was very finely shown, a great mass of pure white that was exceedingly effective.

Sir Trevor Lawrence, Bart., sent a handsome bunch of *Campanula grandiflora semi-plena*, a variety of bold stature and very rich in colour.

A collection of choice and rare flowering plants was shown by Mr. G. Keuthe, Hardy Plant Nursery, Keston, Kent. The collection included *Sedum pulchellum* (the true Bird-foot Stonecrop), *Stokasia cyanea præcox*, *Eruca pinnatis* and *Astilbe simplicifolia*.

SHOW OF GLADIOLI.

There was keen competition for the President's Cup for twenty vases of Gladioli. The English competitors showed excellent spikes of blooms, but they were unquestionably beaten by Messrs. G. Zeebraten and Sons, Oegstgeest, Holland, who staged an exquisite collection. Among the best of the varieties shown were *Baldonia* (blue), *Priniceps* (light red), *Pink Perfection*, *Baron Joseph Hulot* (violet, but not over-vigorous), *Red Emperor*, *Gohath* (crimson purple) and *Moonlight* (soft yellow).

A magnificent display of Gladioli, extending the whole length of the hall (not for competition), was sent by Messrs. Kelway and Son, Langport, who have so long been closely associated with this flower. Every vase in this extensive exhibit contained flowers of the highest perfection. We were particularly impressed with the varieties *Lady Macfarlane*, *Lady Muriel Dugby*, *Colonel Morgan*, *Achvidea*, *Glory of Somerset*, *Royalty* and *Princess Victoria*. Several very promising seedlings under number were also noted.

Messrs. William Cutbush and Son, Highgate, London, N., showed Gladioli in variety. The varieties *Peace*, *Halley*, *Panama* and *America* were shown in quantity, while the centre of the group was filled with the bright purple *Blue* of Baron Joseph Hulot, which everyone admired.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Hydrangea cinerea sterilis.—This woody Hydrangea is worthy of attention, either for conservatory decoration or for planting out of doors. The corymbs of snow white flowers are not so pyramidal as those of *paniculata grandiflora*, nor yet so flat as those of *arborescens*.

Dividing Spring Bedding Plants.—Such plants as Auriculas, Daisies, Primroses, Polyanthus, Saxifragas and many others that are required for spring bedding should now be divided. Break them up into pieces with roots attached, if possible, and plant them in a partially-shaded place in good soil, giving an occasional watering should the weather be at all dry. Wallflowers, Canterbury Bells, Sweet Williams, Foxgloves and other biennials should also be transplanted to get good, sturdy plants for planting out later.

Salvia Grahamii.—This is a plant which deserves to be better known. It is of shrubby habit if permitted, but may be cut down in spring if desired, when it makes a nice, bushy plant. Given good soil and a sunny position, it will attain to 3 feet or 4 feet. The flowers are bright crimson lake in colour, and are produced on slender growths clothed with small, bright green leaves. It is reputed to be rather shy-flowering, but a clump in the gardens at Westwick, Norwich, has proved quite the opposite, having been in flower all the summer.

Seed-Sowing in Late Summer.—Seeds of all bulbous or similar plants should be sown now as soon as ripe. By doing so, much better results are obtained. Seeds of Primulas and many alpine plants are best treated in the same way, as many of them lose a good deal of their vitality through being left till the spring, and, consequently, are much slower in germinating. As seeds of many bulbous plants take several years before they germinate, it is very important to be sure that the seeds which have been sown some time are quite perished before disposing of the soil in which they are placed.

A Charming Californian Plant.—*Platystemon californicus* is a pretty hardy annual not very often seen. Hailing from California, it is known as the Californian Poppy, a title which *Eschscholtzia californica* has also arrogated to itself. Nicholson describes the flowers as yellow, but creamy white is as near the mark, especially in reference to the under side of the petals, which are much in evidence, as the flowers close up early in the afternoon and remain closed on dull days, when they give the suggestion of creamy white Snowdrops. It is a desirable dwarf hardy annual.

Butterflies and Caterpillars.—During the past ten days or so there have been great numbers of butterflies about, chiefly the large white Cabbage butterfly. In past seasons caterpillars have, in many instances, entirely destroyed Cabbages and Cauliflowers in some town gardens, leaving

only the main stem and ribs of the leaves. Cultivators should, where they possess only a few plants, carefully examine the under sides of the leaves and destroy the clusters of eggs often found there. Where there are large breadths of plants, vigorously shake the leaves, dislodge the eggs, scatter a small quantity of dust-dry lime on the soil, and then rake it over with an iron-toothed rake. Both eggs and early caterpillars will thus be destroyed wholesale.

The Barberton Daisy.—For several weeks past a long, narrow border at the foot of the Orchid houses at Kew has been made very effective by the flowers of this South African Composite. Known under the name of *Gerbera Jamesoni*, the species has made rapid strides in public favour during the last twelve or fifteen years, for twenty years ago it was scarcely known outside botanic gardens. The warm, sunny position in which the above-mentioned plants are growing evidently ensures the exact conditions they desire, for every plant is a well-developed specimen bearing a profusion of well-grown, healthy leaves, and a large number of inflorescences borne upon long, sturdy stalks. The larger inflorescences are upwards of three inches across, and the colour is, in most cases, the rich scarlet peculiar to the best forms.

A New Wild Rose.—Lovers of the beautiful single Roses will welcome the advent of *Rosa sertata*, a new variety from China. We owe its introduction to Mr. E. H. Wilson, who also sent home two other recent additions to our wild Roses, e.g., *R. Moyesi* and *R. Willmottii*. *R. sertata* forms an attractive bush 4 feet to 5 feet high, with elegant, glaucous green foliage. From mid-June onwards, for a month or rather more, appear a profusion of delicate rose pink blooms 2 inches or rather more in diameter. These are followed by quantities of bright red fruits, which hang in small clusters, two, three, or more together, from the long, arching growths. The fruits are about three-quarters of an inch long, sub-globose or urceolate. *R. sertata* will make a nice Rose for hedges, being well furnished to the base.

A Good Californian Lilac.—The various ever-green kinds of *Ceanothus* form excellent wall plants, but possibly none is better than *C. thyrsiflorus* griseus so far as free-flowering qualities go. *C. thyrsiflorus* is known as the Californian Lilac, but the variety under notice can, perhaps, lay better claim to that name, for the flowers of the type are blue, while those of the variety are pale mauve in colour and are borne in larger heads than those of the type. *C. thyrsiflorus* is one of the hardiest of the spring-flowering kinds, and grows into a large bush in the open ground at Kew. The variety is, however, grown on walls, and few objects attract more attention during late May, for every branchlet is terminated with a fine inflorescence. Anyone who has wall space to spare, whether it faces east, south, or west, might give this and other *Ceanothus* a trial.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Ornamental Gourds at Edinburgh.—In some of the beds in Princes Street Gardens, Edinburgh, several varieties of ornamental Gourds with ripe fruit have been used as dot plants, with good effect. The only drawback in connection with them is the innumerable questions asked by visitors, including earnest enquiries as to how they should be served at table.—VISITOR.

Anemone japonica Gracieuse.—I am not sure whether this double Japanese Anemone emanated from Nancy or Paris, but it is a most desirable variety. It is the most vigorous of all the varieties which I have seen, including the type. In colour it does not vary much from several other varieties, but it is most floriferous, each stem bearing from ten to fourteen flowers.—C. C.

Olearias and Ceanothuses in our best cultivated borders, but more a subject to use freely in the less important shrubby borders and grow in masses in the open woodland or semi-wild parts of the pleasure grounds. The double pink blossoms are borne at the ends of the shoots in long, terminal panicles, and might be very well compared to a double pink Daisy, so numerous and closely set are the petals. *Rubus fruticosus roseo pleno* and *R. ulmifolius flore pleno* are the two best-known names of this Bramble, though at various times it has had at least two more.—A. B.

Eucharis grandiflora, or, as it is more often named, *E. amazonica*, although introduced from New Grenada in 1854, still occupies a prominent position in any collection of exotic plants. Its beautiful, shining, Aspidistra-like foliage gives it a charm even when not in flower. It forms at all times an excellent subject for the stove, where it enjoys during active growth a maximum amount

siftings. Some years ago the plant was badly attacked by Eucharis mite, showing distinct red streaks above and below the soil on the leaf-stalks. Repeated applications of lime-water gave good results. It would appear almost unnecessary, considering the large quantity of water required during the periods of active growth, to say that perfect drainage is essential to success.—MARK WEBSTER, *Kelsey Park Gardens, Beckenham, Kent.*

The Charm of Clarkias.—Judging from notices in THE GARDEN, considerable attention is being given to these lovely annuals at the present time, and no wonder, for some of the newer double varieties are great improvements on the old single ones. Three particularly beautiful ones which I have seen this summer are Orange King, Queen Mary and Purple Prince. The last is of that unfortunate magenta shade which never seems to have many friends, but which is not bad when you get it alone. Queen Mary is a rich deep rose, very bright and most effective, as visitors who saw it at the "International" will remember. Orange King is a rich cerise pink, the middle of the flower being the darker. As pot plants for conservatory, corridor, hall, or large drawing-room decoration they are superb. I was talking to Mr. N. F. Barnes of Eaton Hall Gardens at our local show not long since, and I was delighted to find him equally enthusiastic over the merits of Clarkias generally when grown in pots. He said how well the soft pink and rose shades blend with the mauves and pale heliotropes of *Schizanthus*. Their culture is of the simplest, and they seem able to adapt themselves to different sizes of pots and to bloom freely in all of them—the rule being the larger the pot the taller the plant, and *vice versa* in reason—the minimum size that I would advise being a 5½-inch.—JOSEPH JACOB.

Musk Losing Its Scent.—I see it is suggested in your issue for August 9, page 395, that Musk never did smell stronger than it does to-day. I cannot say that I ever found an outdoor specimen with a strong scent, but years ago I distinctly remember a sunny greenhouse filled in the spring with the delightful perfume of this plant. I have lately raised plants from seed and obtained them from various sources, but they have all been nearly scentless, and friends have remarked on the same peculiarity. The scent of plants, however, is not a mere freak of Nature, but is produced to attract insects to the blossoms, as was pointed out by another correspondent some weeks back. For this reason the scent is most apparent when conditions of atmosphere favour the visits of the fertilising insects. Thus, some plants smell most strongly after rain; others when the air is sultry; others, which are visited by night insects, only smell after sunset. The ordinary little yellow pot Musk is, I believe, a native of North-West America, and was not known in England till after 1826. It brought its scent with it when it came to us, but it is not improbable that the insects which fertilise it in its native home are not known in our island. It has, therefore, been obliged to fall back on some other means of fertilisation, and its scent, being no longer useful to it, has gradually disappeared, vanishing first from those plants grown in the open, where colder conditions seemed most unfavourable to insect visitors. It was not until the scent had almost vanished that the fact was brought to general notice. I give this suggestion for what it is worth, but it would be interesting to know whether Musk still smells in its native haunts and by what insects it is fertilised there.—E. A. P.

A FINE PLANT OF EUCHARIS GRANDIFLORA GROWN BY MR WEBSTER AT BECKENHAM.

Huge Rhododendrons.—"S. A." has an interesting note on the large Rhododendron in the gardens at Culzean Castle, Ayrshire (page 383). It may further interest your readers to know that there is a Rhododendron forest on the estate of the Earl of Malmesbury at Heron Court, Hampshire. Lord Malmesbury very kindly opens the forest mentioned to visitors when the plants are in flower. These Rhododendrons form long avenues, meeting overhead, many of them being of vast proportions. They cover a considerable space, some of which is on a gentle slope, and as the surface soil has been washed away, thousands of huge roots, forming a veritable network, are exposed. The plants are chiefly, I believe, of the ponticum type.—G. G.

An Attractive Double Pink Bramble.—This is one of the showiest of the flowering Brambles, and the fact that it blooms during August, after the majority of the flowering shrubs are past, adds considerably to its value. It is, however, not exactly a shrub to associate with *Eucryphia*,

of both top and bottom heat, with abundant moisture. Unlike most plants, it can be flowered twice or even three times a year by varying treatment. To obtain these results, immediately after flowering active growth should be encouraged by abundant heat and moisture, aided by the application of weak liquid manures (including soot-water) until the new foliage is perfectly developed, a gradual reduction then taking place until the foliage becomes sufficiently hardened to allow removal of the plants to a drier and cooler atmosphere, to remain there until it is desirable they should bloom. During this resting and ripening period only just sufficient water should be applied to prevent the leaves suffering. Six weeks before the blooms are required, all that is necessary is to place the plants in extra heat. Bottom-heat at this stage is a great factor to simultaneous flowering. The plant illustrated is 6 feet in diameter; it produced thirty-six spikes, with an average of five blooms to each. It was grown on from a small plant, potted in loam mixed with old mortar

A Late-Flowering Horse Chestnut.—*Æsculus parviflora*, the Shrubby Buckeye, is an August-flowering shrub of considerable value for the pleasure grounds and shrubbery borders. A native of the South-Eastern United States, when growing in the open it forms a large, shapely bush 8 feet or more in height and sometimes double as much through. When growing in suitable soil and surroundings, suckers push up freely. *Æ. parviflora* has the familiar digitate Chestnut leaf and a long, slender inflorescence of white flowers with prominent stamens. Seeds ripen in this country during a favourable autumn.—O.

Lilium giganteum.—The illustration of the *Liliums* growing in Lady Trevor's garden at Chirk, which appeared on page 382, issue August 2, shows remarkably fine specimens. I have just seen a plant in a sandy border in a town garden in Hampshire. It is a poor plant, and I was told that they—owner and gardener—could not succeed in growing this *Lilium*. In a garden on a hill not far away there has been no difficulty experienced in growing grand plants in a partially-shaded position, which bears out Lady Trevor's contention that a shady place is best.—B.

Convolvulus Heavenly Blue

(*Ipomœa rubro-cœrulea*).—It is not every year that one is able to speak of success out of doors with this most lovely flower, but just now it is a sight worth seeing. On two patches on a wall facing south-west there were, on the morning of August 4, thirty-three and thirty-eight open blooms respectively, the plants in each case growing in light, warm soil, covering only the modest space of 5 feet high by 3½ feet wide. In one of the patches fifteen blooms were so closely grouped together that they all touched or overlapped. The sight of this comparatively large expanse of this most perfect blue was a thing to remember with thankfulness for the gift of such astounding beauty. The flower is of extreme purity, both of form and texture, the wonderful blue being enhanced by a faint suspicion of yellow in the tube. It is a matter for regret that so lovely a thing should be so fugacious, for after midday the flower loses its purity and by the afternoon has turned to a muddy pink. It is only fair to say that the plants were grown from Messrs. Sutton's seeds. It is well to know that so good a strain is available, for in former years the best one could obtain were more rank in growth and the flowers much fewer.—G. JEKYLL.

FORTHCOMING EVENTS.

August 28.—Flower Shows at Dundee (three days) and Sandy.

August 29.—Flower Shows at Dunfermline (two days), Falkirk and Lymington.

August 30.—Flower Shows at East Linton, Melrose, Conway, Penicuik and Whaley Bridge. Co-partnership Festival.

THE FLOWER GARDEN.

THE AMERICAN COWSLIPS.

THE Dodecatheons, American Cowslips, or Shooting Stars as they are popularly known, belong to the Primula family, though quite unlike them in general appearance. They have, however, the reflexing petals of the Cyclamen, which also belong to the same great family; nothing, however, to suggest that they are allied to the Primroses. Both botanically and horticulturally they may be regarded as a small race, yet, when we have learnt to know them and grow them,

departure from everyday recommendations, and one which, in the briefest of sentences, indicates the position these plants prefer as well as soil. This to the amateur or beginner who knows but little of the requirements of his plants, we regard as important—educational in the highest degree. Such information prevents a cool or moisture-loving plant being placed in the sunny border to starve at the outset, and affords encouragement to the planter to continue his work. These American Cowslips blossom in our gardens in springtime, though for the most part in May and early June. It cannot be said of any of them that they possess great vigour; *D. Jeffreyi* is the most vigorous of them all. Their greater attributes

are perfect hardiness, freedom of flowering when well suited, and a grace and charm none will deny. They are of the true deciduous perennial class, *i.e.*, they die completely to the earth each year, losing both leaves and stems in the great majority of instances. Whether such plants are more complete in their hardiness because of the fact might prove a moot point; in any case they lend themselves to liberal mulchings of soil or manure in a way that many plants do not. It will be seen, too, by a close observance of the rootstock that such mulchings are essential, inasmuch as there is a marked tendency in the established examples to lift themselves slightly above the soil. Hence an inch-thick mulch of rich soil—half loam, half well-decayed manure—may be given each year in early autumn with advantage. So graceful and pretty in effect are these plants that, apart from a general recommendation to plant in cool and shady places, they may also be planted in cool recesses in the rock garden where sheltering bank or rock exists behind. Upon more than one occasion when experimenting with hardy plants we have given them positions in the bog, treating them in winter-time to free applications of liquid manure, the result convincing us that the twain were quite congenial to their well-being.

Cultural Hints.—Generally speaking, the plants are rather slow to establish; hence should not

frequently be disturbed. For this reason a deep bed of rich soil should be prepared, and young plants, preferably strong seedlings, put out in plenty. Where divided plants are employed, the divisions should be made rather small, as these, in common with not a few herbaceous subjects, do not retake kindly to the soil when planted in large clumps. The best methods of increase are by seeds, which should be sown soon after maturing, and by root cuttings, which is perhaps the most expeditious of all. In the case of any particularly good variety it is without an equal, but it can only be employed advantageously when the plants are dormant. As there is not a

AMERICAN COWSLIPS OR SHOOTING STARS (*DODECATHEON MEADIA*).

they have quite an importance of their own. We say this much advisedly, because of the too frequent text-book recommendations that these plants—and not these alone—are particularly partial to "light, gritty loam." So often does one meet with these or similar words to indicate the class of soil in which a plant should be grown that not only do they appear in the nature of a stock phrase, from which apparently there is no departing, but the reader comes to regard them lightly and as having but little importance. In "The Hardy Flower Book" (Jenkins) we are told that they "love cool and shady places in peat and loam," a slight

great variety of colour at present existing, hybridising may be found of interest to those engaging in the improvement of hardy plants generally. The best planting season is early autumn, though it may be done at other seasons when youthful plants are established in pots. The following are some of the leading kinds now in cultivation:

D. integrifolium.—A rather dwarf plant of not more than 6 inches to 8 inches high, and, without doubt, the richest coloured of all. The predominant colour is deep crimson, the base of the petals white, emerging from an orange-coloured cup. Rocky Mountains. A deeper-coloured variety of this plant is often catalogued as *splendens*.

D. Jeffreyi.—The tallest and most vigorous growing of the race, quite distinct in these respects and in habit general, while resembling a rather deep-coloured form of *D. Meadia* in its flowers. Quite 2 feet in height in the ordinary way, the plant reaches its fullest development in moist clay. It succeeds admirably, however, in deep, rich loam with abundant moisture. A little of the vigour of this fine plant in the dwarfier and more richly-coloured varieties would be very acceptable. It is certainly worthy of the thought of the intelligent hybridist.

D. Meadia (see illustration).—It is this species and its varieties that are best known to cultivators. It is a choice and elegant-growing herbaceous plant of 12 inches or 15 inches high, more slender or graceful of stem than the last named, and bearing umbels of drooping flowers, as shown in the illustration. The predominant colour of the petals is purplish; in some varieties it is bluish or lilac. There is also a white variety, *D. M. alba*. Distinctive varieties bearing such names as *elegans*, *splendidum*, *blacinum* and *giganteum* also occur in the catalogues of the specialists, and these, planted separately in colours or in mixture, are capable of providing pretty effects either in the rock or bog garden.

HARDY ANNUALS FOR AUTUMN SOWING.

It is doubtful whether there is any other class of plants which by the expenditure of a few shillings in the purchase of seeds will produce such a variety and brilliant display of flowers for garden decoration and cutting. Annuals are quite as valuable in the small garden as in the large one. The time to sow the seeds is a matter requiring consideration, and a subject about which no hard-and-fast lines can be followed. The nature of the soil in the garden, whether heavy or light, the locality where the garden is situated, and its position, whether favourably placed for sun and screened from cold winds, or very much shut in and enclosed, making it unsuitable for some plants, are all matters that need attention. There are points in favour of both autumn and spring sowing, which it will be just as well to survey before dealing in detail with the different sorts or varieties of annuals. First of all, let it be clearly understood that if full advantage is to be taken of the great value of hardy annuals in the garden, both autumn and spring sowing of the seeds in some way or another must be practised. By sowing the seeds at different times and under several conditions, the flowering season is considerably prolonged and the varied requirements of the respective annuals suited.

Cultivation on Heavy Soils.—Sowing seeds on soils of a clayey nature which are heavy and wet is not a profitable business in autumn. Failures and losses are usually considerable. The most notable exception are Poppies, which survive an ordinary winter on heavy ground very well. The best method of procedure for annuals on such soils is to set apart a border in a warm and sheltered position, under a wall or fence with a south or south-west exposure, in which to raise the seedlings. Thorough drainage of the seed-bed in winter being of the utmost importance, 6 inches to 9 inches of the top soil should be removed and replaced with a similar amount of clinkers and ashes. A compost of light, sandy soil to the depth of about six inches must be spread over this, so that the seed-bed is raised well above the ground-level, similar to an Asparagus-bed, for instance. In most instances this will be sufficient; but if more protection is required, a handy-man with a few boards and several odd lights will soon fix up a temporary frame. It will be preferable to place the boards in position previous to sowing the seeds, but the lights should only be used during bad weather, e.g., severe frost, heavy rains, or snow. Always remember that, however much care and attention we devote to the culture of autumn-sown annuals, they are hardy plants, and must not be unduly coddled, simply protecting them against the extremes of our variable British climate.

Sowing in Light or Sandy Soil.—In gardens where the soil is fairly light and well drained, the most satisfactory results, with a few exceptions, are obtained by sowing the seeds where it is intended the plants should flower. This, however, is not always possible, for the ground may not be available when it is time to sow the seeds, being occupied with other plants still in bloom. Here, again, the reserve border will be useful in which to raise the seedlings, transferring them to their flowering quarters a couple of months later, or in late March and early April, whenever the ground is vacant. There are two methods of sowing the seeds, one of which is broadcast, that is, scattering the seeds thinly and evenly all over the surface of the ground, afterwards raking it thoroughly to bury the seeds. With one or two exceptions, notably Sweet Peas, this is the usual procedure when sowing the seeds where the plants are to flower. Sowing in drills or straight lines 1 inch to 1½ inches deep, made with a draw hoe, is the preferable method when transplanting is intended, filling in the shallow drills by carefully raking over the surface after sowing. Lifting the seedlings is much easier for transplanting when they are in straight lines.

The ground for transplanted seedlings should, if possible, be prepared a month before it is required, to allow it to settle down and be in good condition for planting. Too much emphasis cannot be laid on thin sowing. In the first place, it is waste of seeds to sow otherwise, and then in a crowded seed-bed the seedlings become drawn and sickly, have more difficulty in surviving the winter, take a lot more looking after before the flowering stage is reached, perhaps require a stake for support, and certainly do not flower so freely and make such a good show as a well-grown, sturdy plant from birth. When a quantity of fine seeds have to be sown, it considerably facilitates the operation to mix the seeds with sand. In this way a thin and even distribution of the seeds is obtained when sowing broadcast.

(To be continued.)

TREES AND SHRUBS.

THE AUGUST-FLOWERING CLEMATISES.

BEAUTIFUL at whatever season of the year they flower, those Clematise which blossom in August are particularly valuable, as at this season there are comparatively few shrubs flowering in the pleasure grounds and shrubbery borders. As they vary in height from about three feet to fifteen feet or more, there are a variety of ways in which they may be effectively planted. All those mentioned in these notes require support of some kind, varying from a few short Pea-sticks in the case of the shorter-growing ones to tall rustic poles. These August-flowering Clematise should be freely planted in town and suburban gardens, being admirably adapted for clothing fences, rustic arches, porches, screens, trellis-work and arbours. They also seem to succeed in the soils of such gardens, presumably because the builder leaves plenty of mortar rubble and broken bricks behind, to which Clematis plants are partial.

The Lady's Bower (*C. Viticella* and its varieties) has flowers of moderate size, and succeeds better in most gardens than the larger-flowered *C. Jackmani* and *C. lanuginosa* types, not being liable to collapse suddenly. Hardy and vigorous in growth, the varieties of *C. Viticella* produce long, graceful growths, which may be looped loosely to rustic arches, fences and arbours, with pleasing results. A good range of colour is available, there being numerous shades of blue, red and pure white. A selection of the best sorts should include *alba*, *rubra*, *atrorubens*, *Ville de Lyon*, *ascotensis*, and *Viticella* the type. There is a double variety, *flore pleno*, but the flowers are not so attractive as the single ones. Three rustic poles with spurs fixed tripod fashion, 8 feet to 10 feet high, look very effective in a shrubbery border clothed with *C. Viticella*.

C. Pseudo-flammula is a delightful small-flowered, upright-growing species, producing a wealth of creamy white blossoms in the way of *C. recta*. It attains about five feet in height, requiring only the support of a few Pea-sticks. A native of the Caucasus, *C. Pseudo-flammula* is at its best the first week in August, two to three weeks in advance of that species. It is also not nearly so tall in growth, not perhaps, strictly speaking, being a climber. The flowers are deliciously fragrant, suggesting Vanilla.

Quite a number of the smaller-flowered Clematise blossom during the present month. Those with the elegant, drooping, bell-shaped blossoms prettily recurved at the edges deserve attention, being very floriferous and easy to cultivate. Supported with a few short Pea-sticks, *C. integrifolia* (purple), varieties *rosea* and *alba* attain a height of 3 feet to 5 feet or more. *C. globosa* and *C. intermedia* are evidently hybrids of *C. integrifolia*, resembling that species in growth and shape of the flowers, but the latter are a little larger and have more substance.

Two hybrids (*C. Viticella* × *C. integrifolia*) named *C. Hendersonii* and *C. Clocheton*, both with dark purple flowers, are very free-flowering, and attain a height of 6 feet in the case of *C. Hendersonii*, but *C. Clocheton*, though not so tall, is perhaps a little sturdier in growth. In the graceful, drooping poise of the flowers the influence of *C. integrifolia* is readily seen. *C. Durandii* is another *C. integrifolia* hybrid, but in this case

the large, flat flowers, 5 inches across, take after the large-flowered parent. *C. Durandii* has purple flowers, while another sort similar in form named *C. pallida* has lighter-coloured blossoms. Both are free in growth and adapted for arches, pillars and clothing tall fences.

C. Flammula rubro-marginata is a dainty, small-flowered variety with white blossoms prettily margined with rosy purple. The slender, trailing growths may be utilised for clothing porches, verandahs, &c., where the deliciously fragrant blossoms will be appreciated.

It is during August that the Jackmann Clematises are at their best. Though hundreds are planted every year, their successful cultivation is not general. Observations of plants in a thriving condition suggest that they do not like the hot sun shining on the stems. Deep planting is another fault, and the soil, though rich, should be well drained and contain plenty of lime—mortar rubble, for instance. There are several ways in which the sun shining on the bark of the stem may be prevented. Plant on a west or north-west aspect against a porch, verandah, wall, or fence. Associate with the Clematis a white Jessamine or Honey-suckle, and plant them in the shrubbery borders where the shrubs are 4 feet to 5 feet in height,

THE FRAGRANT VIRGIN'S BOWER (CLEMATIS FLAMMULA) GROWING OVER RUSTIC POLES.

or on a fence with shrubs in the foreground to hide the lower part of the stem. A selection of the best of Jackmann's Clematises are Jackmann, violet purple; *J. superba*, very dark violet purple; *J. Snow White*, pure white; *J. rubra*, dark velvety

red; *Gipsy Queen*, velvety purple; and *Mme. E. André*, bright velvety red. Though flowering for some two months past, there are still a considerable number of the showy rich yellow flowers on *C. orientalis* var. *tangutica*. These are followed by fluffy balls of seeds, which add considerably to their attraction. Rambling over a few rough sticks placed against a fence or screen, this Clematis may be expected to thrive.

which occasionally ripen in this country. One looks forward to the time when this rare Chilean shrub becomes a thing of beauty in most gardens of this country.

A LITTLE-KNOWN CHILIAN SHRUB.

(*EUCRYPHIA PINNATIFOLIA*.)

THE illustration on page 422 shows a beautiful bush of this comparatively rare Chilean shrub flowering at Kew. Although introduced as long ago as 1862, it has never become common in gardens, presumably because many of the bushes have not been planted in positions favourable to their growth. Naturally, when planting choice treasures such as this *Eucryphia*, what are supposed to be the most favourable spots are chosen. Probably in most instances this shrub has been planted at the foot of a sunny south

wall where the soil is dry. Experience with the *Eucryphias* at Kew points to these conditions being unfavourable, for while a little protection may be desirable, moisture and shelter from the fiercest rays of the sun are more important.

The plant illustrated, growing in a bed of the Mediterranean Heath 2½ feet to 3 feet high, is evidently happy in its surroundings. The Heaths keep the ground cool and shade the lower part of the plant. Shelter from intense sun-heat is afforded by tall trees growing at a distance, though this point does not seem so important as the prevention of the baking of the surface soil.

The Kew plants are growing in sandy loam, with a little peat and leaf-mould worked in previous to planting. An occasional top-dressing of decayed leaves is beneficial. The largest bush is 10 feet high and clothed with white flowers 2½ inches to 3 inches across, not unlike a large single Rose, with a tuft of stamens in the centre. *E. pinnatifolia* is an evergreen, and may

CLEMATIS VITI FLOA ALBA, A VIGOROUS-GROWING VARIETY SUITABLE FOR CLOTHING LOW TREES.

CLEMATIS PSEUDO FLAMMULA. THE FLOWERS ARE DELICIOUSLY FRAGRANT SUGGESTING VANILLA.

THE GREENHOUSE. ON SCENTED PELARGONIUMS.

(Continued from page 412.)

3. Classification.—This brings me to one of the great difficulties of forming a collection. There are a certain number of groups of Pelargoniums whose parentage and antiquity are beyond dispute. Of these the cucullatus head the list with *P. cucullatum* of the date 1690, which a lady from the Cape told me at the Royal International Horticultural Exhibition grows all over Table Mountain. This I believe to be the parent of most of the show Pelargoniums. The next oldest group seem to be the capitatus, of which the somewhat rare variety I have is, I believe, the ancestor, introduced also in 1690. Roseum, graveolens and blandfordianum are all well-known relatives, with others too numerous to mention. Then there is the large group of citriodorums, delightful, every one of them, to sight and smell. *P. grossularioides*, introduced 1731, is the oldest species I have been able so far to unearth. The quercifoliums and their near relations the denticulatus (where does one end and the other begin?), with quercifolium minus, a true Cape species, introduced 1774, and denticulatum (1789), at the head of the family tree, form another large and well-defined group. And there is the modern group of Sbrubland hybrids I have already mentioned. No one could ever class them with anything but scented Pelargoniums.

These groups are all distinct from each other, and fairly easy to discriminate. But many others are difficult to place, unless their parentage can be traced. And even so it is not a light task, as, according to Sweet, they were hybridised in and in. But it is when one comes to try to draw the line between the tuberous-rooted Cape Pelargoniums on one end of the scale and the modern show Pelargoniums at the other, and make up one's mind as to how many and which are to be included in a collection of scented Pelargoniums, that the fun begins. To start with the Cape Pelargoniums. They are undoubtedly the original importations, but many of them—*bicolor*, *ardens*, *fulgidum*, *pulverulentum*—are absolutely scentless. Yet if you study the pedigree of, say, *pyrethriifolium* (Scarlet Pet), you will find that one parent is *fulgidum*. If you therefore include the child, why ostracise the parent?

Again, we turn to the other end of the story. Half the old show Pelargoniums are hybrids from a scented Pelargonium on one side; and *P. cucullatum*, as I said before, is responsible for a very long family. So where one ends and the other begins is more than I can say, and wiser heads than mine must determine the limits of scented Pelargoniums and show Pelargoniums, and solve

this puzzle for us amateurs; and also the other question of nomenclature, on which I touched in my former article. I look to Wisley to take these matters in hand, for I consider the classification and proper naming of specimens the two main stumbling-blocks in forming a collection. Meanwhile, let me give the intending collector this piece of advice: "Never discard any real old variety of Pelargonium you come across. It may not be a true scented Pelargonium, but it may help to throw light on the pedigree and development of some hitherto puzzling specimen." Before leaving this part of my subject I should like to call your attention to those specimens of the allied types of Geraniaceæ, which I alluded to just now

dasycaule, *P. ceratophyllum*, *P. alternans* (*P. crithmifolium*) and some others." Up till now I have acquired no specimens of the Hoareas, Grevilleas, &c.

(3) *Ciconiums* are, I think, undoubtedly the forbears of our modern Zonals. *Ciconium umbellatum* is interesting as being a curious and, I believe, early form, but I have no idea what the date of introduction is. *C. crenatum* (1820 about) is a true Cape species, of which I possess a small plant, but unluckily it has refused to flower in time for to-day.

(4) *P. fulgidum*, which also refuses to flower when I want it to, is parent of several of the showiest scented Pelargoniums, and is a case in point of what I was saying just now of the difficulty of drawing the line between scented and unscented. Rollison's Unique, *Ardens* and Scarlet Pet are all its progeny, crossed with some other varieties.

(5) *P. gibbosum*, the *P. glaucum* of Kew, is another I include as a sweet-scented variety, for it is very fragrant, but at night only. It is a true Cape species of an early date, 1712.

(6) *P. Godfrey's Pet*. This is the most interesting modern hybrid I have ever come across, for after careful study I have come to the conclusion that Messrs. Godfrey of Exmouth have happened by chance on an old cross. This variety resembles in every respect the *P. obscurum* of Sweet, Vol. I., page 89. (Parentage unknown, raised from seed by Sir R. C. Hoare in 1821.)

(7) *P. Miss Dorrien-Smith*. This is interesting as one of the old varieties of the Unique section. It is the *P. breesianum* of Sweet, Vol. I., page 64, and a hybrid between *P. angustifolium* or *quercifolium* and one of the round-leaved varieties unknown.

4. Cultivation.—*Cuttings.*—The best months to take cuttings are February and August, and all the citriodorums strike easiest in February.

Soil.—As a broad general rule, sand, peat, or leaf-mould, and turfy loam are best. Sweet's proportions are equal parts of sand, peat and turfy loam. But we find one part of leaf-mould to three of turfy loam, and one shovelful of silver sand to a barrow-load of this, a very useful and successful mixture. For the real tuberous-rooted Capes you

want more sand, and to pot them less firmly. Bottom-heat is not necessary. We always strike ours in a cool greenhouse. I forgot to say, under the head of cuttings, that there are several of the Cape species which can only be propagated by tubers; such are *P. triste*, *P. pulverulentum* and *P. ardens*.

Watering.—This requires great care. When in full growth, water may be given fairly freely; but as soon as the plants begin to rest, err on the dry side; in fact, according to Sweet, the tuberous-rooted varieties only require watering two or three times during the whole winter!

THE BEAUTIFUL *LUCRYPHIA PINNATIFOLIA* NOW FLOWERING IN THE HEATH GARDEN AT KEW. (See page 421.)

as off-shoots of our main subject. Some of them will illustrate what I meant as to the difficulty of knowing what to include in a collection.

(1) *P. tetragonum*. I find this is given in Sweet as a *Jenkinsonia*—*J. tetragona*, date 1774. Its leaves are undoubtedly sweet-scented, so I include it in my collection.

(2) *P. carnosum* (Kew) is Sweet's *Otidia carnosum*. A good distinct specimen of the *Otidias*. Sweet says of it, Vol. I., page 98: "This plant, which is so very different from any we have yet published, is proposed by Mr. Lindley to form a distinct genus, which we have adopted; to it also belong *P.*

Draughts.—These are one of the worst enemies to Pelargoniums, and must be carefully guarded against. Draughts encourage the most troublesome pest there is—aphis.

Pests.—Aphis and thrip. For the former we fumigate with nicotine and syringe with plain water; for the latter we sponge the leaves with an insecticide, such as paraffin solution.

Since delivering the foregoing lecture, Mr. J. Hudson, V.M.H., has most kindly sent me the following notes on the cultivation of scented and Cape Pelargoniums, the result of his long experience in growing this class of plants: "Miss Troyte-Bullock's remarks upon the soil induce me to say that I find finely-granulated lime to be excellent; it assists in keeping the soil sweet and open. Firm potting is most essential for the durability and healthy growth of the plants. In the winter I find it much better to keep the soil quite on the dry side in dealing with our large specimen plants, and small plants require a little more water in proportion; but it is better to keep them resting during the dull season of the year. It is a pity that no records are, so far as I know, available as to the history of many of these most interesting, if not showy, plants. When the present collection at Wisley is arranged into something like order, we may probably get to know more about them—their needs, their uses and their varied characteristics."

DAFFODIL NOTES.

Daffodils in Pots.—The Editor has recently received a letter from a reader asking if I grow my choice Daffodils out of doors or in pots under glass. As I understand the writer, he seems surprised that I adopt the first method. He obviously thinks the second way preferable. I cannot agree with him. The strain imposed upon the bulbs when they are grown in this non-natural manner is great, and, even with the greatest care in their treatment after the flowers are over, there is a most marked difference in their size and general appearance compared with those grown in the natural way. I would advise everyone to adopt the out-of-door system as their normal practice. It is a long way the best for the bulbs, and after one has given a big price for an expensive kind, one wishes to do everything that can be done for it. I have somewhat enlarged upon and emphasised my answer, because I am going to write of Daffodils in pots and try to persuade everyone who has not already done so to grow some of the better varieties in this way, not because I consider it the *best for them*, but because of the *enjoyment which it affords us*. I believe there is a great future for this method of culture, and that it will become very popular when once its possibilities are realised; but it must be remembered that even with the very best treatment the bulbs suffer, and that before they are used again they must have at least one year in the open ground. Daffodils make splendid pot plants, and they are easier to manage than either Hyacinths or Tulips. Two essentials for success are (1) early potting and (2) choice of suitable varieties.

Bulbs should be potted as soon as they can be had from the dealers, and then the pots should be stood on a hard bottom and the spaces between them filled up with sand or fibre, the whole being covered with the same to a depth of about three inches. Later on, about the middle of November, when hard frosts may be expected, the pots may

be placed in frames from which frost can be excluded and given abundance of air whenever it is possible, or another 3 inches or 4 inches of covering material may be added to make them more frost-proof if they are to remain in the open. As I am now dealing entirely with Daffodils as pot plants, I would never advise anyone to try to get them in flower very early; almost invariably they are rather drawn and weak in the foliage, and need too much staking to look really well. In my opinion the third or fourth week in January is quite soon enough. From this time onwards there should be no difficulty in having a good succession of bloom.

Making suggestions about the varieties to grow is a difficult matter, for the choice is very great and everyone does not like the same thing equally well. My best plan is to indicate some of the most satisfactory ones that I had myself last year. In the front rank I always place W. P. Milner, which is a dwarf, slender plant of the trumpet section and which under glass comes almost white; 5-inch or 5½-inch pots are quite large enough to grow it in. As a contrast I mention

Jouison, one of the most satisfactory of all the older Poet introductions of Mr. Engleheart. Another group which has great value for pot culture is that of the Leeds. Fairy Queen is now becoming better known. I might call it the "Autocrat" in the same way as I style Countess of Southesk the Frank Miles of the section. Both are excellent and will not disappoint. The "giants" must have a great future. I look forward to the time when we shall have warm apricots like Thera; yellows like Evangeline, Longfellow, Louise L. Linton, and several of larger build not yet in commerce, but whose place can be supplied now by Lady Margaret Boscawen; and ivory whites or very pale primroses, such as Empire, White Countess, Potent and St. Olaf. These "flowers of purest ray serene" are now carefully guarded, and need a golden or a silver key to liberate them. Some day a copper one will free them, and then they will be everyone's plants, like Golden Spur and Emperor. Among the bicolor and self-incomparabises and Barris I must not omit Autocrat, Homespun, Solfatara, Scagull, Incognita and Leone. Before I conclude this

A FLOWERING SPRAY OF EUCRYPHIA PINNATIFOLIA.

Olympia, an immense yellow Ajax, not perhaps as sleek and smooth as a judge would like at a show, but a wonderfully effective and striking bloom. Another good variety of the same type, but with paler colouring and rather more of a show style of flower, is Stromboli. This variety is not half as much known as it should be. Few "come" so easily as this does under glass. It is almost superfluous to sing the praises of Weardale Perfection in pots. It is one of the very best. Coronet is another kind that should have more recognition from growers. It, too, "comes" easily and early. It is a medium-sized bicolor trumpet, with the yellow of a peculiarly deep shade. Firebrand always does well. Now that it can be bought so cheaply, everyone should order a few for trial. The red does not burn under glass, or, if it does, it is not perceptible for a considerable time. In this category I include such varieties as Blackwell, Lucifer, Crown Prince, Robert Browning, Topaz, Southern Star, Castile, and Ben

list I must put in a special plea for Queen of Spain. In the low pots that I am so fond of, nothing looks better, and I have found that it can be grown from year to year in this way if the bulbs are well and carefully dried off and then repotted. I had almost forgotten to mention the Tazettas and Tazetta hybrids, or Poetaz. The former old-time favourites are not nearly so much grown as they were twenty years and more ago. They are very easy to manage, but they must be procured every year from Holland for the best results. Bazelman Major, Maestro and a new one, Dr. Holland, that I have lately unearthed are three that might well be given a trial. Of the Poetaz I am very fond of Irene, Sunset and Jaune à Merville as yellows, and of Aspasia, Orient and Alsace as whites. The latter, on account of its earliness, is very valuable. If Aspasia is grown, Elvira is not wanted. The charm of Orient is the delicate red edge of its cup, which is always very noticeable when it is grown under glass.

JOSEPH JACOB

CUT FLOWERS.

THEIR VALUE IN THE HOUSE.

AN authority one cannot but respect thinks it dreadfully barbarous, not to say wicked, to pick flowers. This is what he says, or rather one of the things he says: "I hold that a flower cut from its plant and placed in a vase is as a scalp on the walls of a wigwam." He goes on to say even worse things; I say "worse" because they make you feel uncomfortable. "The cut flower," he declares, "is no longer part of a manifestation of the will of Nature; rather is it a slave—beautiful, it may be, but branded and soul-destroyed." But is not this going too far? If none of us gathered flowers to enjoy them indoors (perhaps wearing them *is* different), a large amount of innocent pleasure would be lost. It is not as if it hurt the flowers to pick them. Judicious use of the knife and scissors helps a plant instead of hindering it, and some flowers seem really made to be picked. Sweet Peas, for instance, the more you pick them the faster they grow. And did not a poet say of Sweet Peas that they always seem "on tip-toe, ready for a flight"? It is seldom worth while nowadays to save seed; so what is to be gained by letting each dainty blossom fade away upon its stem like a pretty girl unappreciated?

A word of excuse is said by our critic for those users of cut flowers, indoors and otherwise, who have the misfortune to live in London. In such cases, gathered flowers, he admits, "carry the mind to beautiful associations." But is there nothing to be said for cut flowers in the case of country houses? Sometimes the rooms in these are dark and low-pitched, and want brightening up as much as any London ones with their big windows and white paint. For our own parts we confess without shame that we even plant certain flowers with no other object than that of gathering the blossoms they give us to adorn such rooms as we think would be the better for them.

In one or two rooms we fancy nothing looks so well as pink. Accordingly we take care to have plenty of Shirley Poppies, Monthly Roses, pink Sweet Peas, pink Geraniums, rosy Mallows and all the other pretty pink flowers we can think of, always ready to bring in. It is quite an art worth studying, that of growing such flowers as are best for indoor use—the bold plants that belong to hall and staircase, such as Foxgloves, giant Poppies, tall Lilies, Lupines and so on; the bright but scentless flowers that are most suitable for the dinner-table; and the host of other charming flowers one likes to have in living-rooms.

The delicate shaded pinks and rose colours of Shirley Poppies are so delightful standing in moss on dinner-tables, or indeed anywhere, that we resort to a cunning way of getting them before

anyone else has them. How? Well, nothing simpler. We scatter seed on a fair-sized plot about the middle of August. By the following May the flowers will be ready, and will go on blooming till July or longer. The flowers, grown thus, are much hardier than when sown in spring for summer gathering; their stems are thicker and stronger, and the petals of the blossoms do not drop. In fact, the whole character of the Poppy seems altered; no doubt it pays for bracing treatment. How human!

Another way of looking at the subject is to remember the pleasure given us by the cut flowers sent from abroad. Those wicker baskets so

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Gladiolus Craig-a-Noor.—This is a very handsome red-flowered variety whose lower petals are marked by a few faint white lines. The size of the flower and its form suggest influence from *G. princeps*. The spike is well filled. From Messrs. Kelway and Son, Langport.

Dahlia Dungeness (Collarette).—The florets are coloured a rich scarlet, the collarette or inner petals surrounding the disc yellow. From Messrs. Dobbie and Co., Edinburgh.

Caladium Mme. Renee Marot.—

This rather striking red-leaved variety has a copious spotting of white, which renders it attractive and distinct. From Mr. Hoffman, Tower House, Streatham.

Lysinotus warleyensis.—A new Chinese plant of evergreen, shrubby habit. The exhibited example was not more than 9 inches high, the white, Pentstemon-like flowers issuing from the axils of the leaves on slender pedicels. Internally the flowers, which are 1½ inches long or thereabouts, are marked by three purplish lines. Its complete hardiness has yet to be determined. From Miss Willmott, Warley Place.

Agapanthus Weilligii.—The distinctive features of this rather good African Lily are that the flowers are nearly cylindrical, being slightly expanded at the mouth, and drooping instead of erect or semi-erect as in the typical kind. This unusual feature shows the rich blue flowers to advantage. A distinct and good plant. From Mr. A. Worsley, Isleworth.

The foregoing awards were made by the Royal Horticultural Society on August 12 at the fortnightly exhibition.

A NEW CHINESE SHRUB.

(*SPIRÆA ARBOREA GRANDIS*.)

This is a very strong-growing shrubby *Spiræa* belonging to the *Sorbaria* section of the genus. *S. arborea* is a variable species, and several of the most distinct forms, in addition to the subject of this note, have been given varietal names. They are closely allied to the well-known *S. Aitchisonii* from

Afghanistan and the Indian *S. lindleyana*. Growing 8 feet or more in height, *S. arborea grandis* has large, attractive, pinnate leaves and small, creamy white flowers. These are borne in large, terminal panicles, roughly triangular in shape, 12 inches to 15 inches long, and 9 inches to 12 inches broad at the base. The flowers are closely arranged in the panicles. This is one of the many beautiful shrubs introduced from China by Mr. E. H. Wilson. Though closely allied to *S. Aitchisonii* and *S. lindleyana*, it will be an addition to our shrubs, as the flowers are borne some three weeks in advance of these two species. *S. arborea grandis* received an award of merit from the Royal Horticultural Society when exhibited by the Hon. Vicary Gibbs on July 29.

SPIRÆA ARBOREA GRANDIS, A NEW SHRUB WITH MASSES OF CREAMY WHITE FLOWERS.

carefully packed with treasures of Mimosa, Carnation and Anemone—what messages they bring us!

The plumed Mimosa, of Spring's gifts finest,
With a golden gleam and a golden voice,
As if from the country of dreams divinest
Cries clear, "Rejoice."

And the white Narcissus that poets honour,
With red gold rimming a pearly cup,
And a silver light, as of stars upon her,
Chimes sweet, "Look up!"

To those who suffer from over-sensitiveness in the matter of cut flowers (and we do sympathise with them in a way) may we suggest that if the flowers themselves were consulted, we are convinced they would never grudge the happiness they give us.

FRANCES A. BARDSWELL.

GARDENING FOR BEGINNERS.

HOW TO GROW ARUM LILIES.

THE leaves of these plants are handsome, and form a very appropriate setting for the flowers. Even when there are no blooms out, the plants help to furnish a greenhouse or conservatory from autumn-time to Easter, and sometimes even later. Strong plants will bear three or four flowers during that period. In exceptional cases they bear five or six. Some cultivators retain the plants in their pots throughout the summer months, keeping them dry at the roots all the time, and then shake away the soil and repot them, dividing some, but retaining others intact. Again, there are cultivators who plant out the Arums directly they have finished flowering. There is a great difference between the two sets of plants. Those retained in flower-pots make dwarfer growth in their early stages than those that are planted out. This difference may be noted in the two sets of sketches, A and B respectively. Without going into the merits of the two methods of growing the plants during the summer-time, I will only say here that it is advisable to retain a few plants in pots every year, as undoubtedly those in the pots commence to flower earlier than the others, and so prolong the supply of blooms considerably.

The Treatment of the Plants in Pots.—In order that the soil may be kept dry around the roots while the plants are being rested, the pots are laid on their sides. About ten days before they are turned out, put the pots upright and water the soil to induce the plants to make a little new growth. In the meantime prepare a number of pots varying in size, as shown in Fig. A. No. 1 denotes drainage, and No. 2 shows the depth of the potting when that work is done. Pots from 3½ inches to 7½ inches across must be got ready. No. 3 shows the ball of soil and the new leaf-stalks. In reducing the soil around the roots

of this and similar clumps, and that from large clumps lifted from the open ground, use a stick as shown in No. 4, first detaching the old crocks, and then gradually working away the old soil and any decayed roots. The new, fleshy roots must be carefully preserved from injury. If potted intact, with only a portion of the old soil removed, No. 5 shows the condition of the plant when it has been duly prepared. After dividing a fairly

large plant, the separate portions will resemble Nos. 6, 7, 8 and 9, No. 9 being the crown of the old plant. The inexperienced cultivator will see at once how necessary it is to repot the various parts in pots of different sizes. I may say that it is rarely necessary to repot Arum Lilies during the winter months. If potted judiciously at first, they will grow nicely through the autumn, winter and early spring months, as they are good subjects to feed.

Fig. B shows how large plants should be lifted from the open border and divided. The best time to divide the plants is when they are first put out; but if the work is not done then, it must be when they are lifted. Drive in the garden fork at a suitable distance from the plant, so as to preserve as many roots as possible. The different parts of such a large plant when duly divided are shown at Nos. 2, 3, 4, 5 and 6. If the big plant, No. 1, were potted whole as lifted, its flowering strength would quickly diminish. The young plants in smaller pots are more serviceable. Nos. 7, 8, 9 and 10 respectively represent the different parts forming a good compost, namely, loam, leaf-soil, rotted manure and sand. After potting, keep the plants in a cool place outside; then transfer them to a frame before frost comes and, in due time, to the greenhouse. G. G.

PARSLEY FOR SUCCESSION.

There is such a demand for Parsley at all seasons that too great care cannot be taken to secure a good succession. The end of June is the most difficult time to cater for; but August sowing ought to provide against a shortage at the time mentioned, this being followed by a very early spring sowing in boxes. If sown now, the seedlings should be ready for thinning in a week or two.

DIVIDING AND REPOTTING THE ARUM LILY.

THE LARGE PLANT IN THE CENTRE, IF DIVIDED, WILL MAKE MANY USEFUL SMALLER PLANTS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Fuchsias.—In fairly sheltered positions Fuchsias are one of the best subjects for making a display during the summer months. Certainly they require a fair amount of moisture all through the season, but given this and a sprinkling of artificial manure every two or three weeks, they continue to make a show till quite late in the summer.

Propagation.—For next season's display the present is a good time to put in cuttings. These should be from the young growing tips, preferably shoots that are not blooming. Very light sandy soil is essential, and if eight or ten cuttings are placed in a 4½-inch pot and plunged in the propagating-frame, they should make root quickly. Potting off into small pots may be done before the winter, when the young plants may be wintered on a shelf in the intermediate house. With such treatment they should make plants quite 4 feet high by planting-out-time next season, and these young plants bloom much more continuously than do the old ones that may have been dried off during the winter.

Montbretias.—These continue to make a good show, and to prolong the flowering period they must not be allowed to get dry. A good soaking or two of liquid manure will do much towards keeping them going. The new variety *Star of the East*, exhibited so well last year, will be much sought after, and it will be a welcome addition to this already beautiful class of plants.

Dahlias are now blooming freely, and to keep up the show give regular soakings of liquid manure. In some varieties the shoots will require a certain amount of thinning for the blooms to develop nicely, and all must be kept well tied to the stakes, or much damage is likely to be done by the gales of wind which we usually get during September.

Plants in Pots.

Bulbs.—If not already done, the list of forcing bulbs should be made out and the order despatched at once. If early bloom is wanted, it is necessary that the bulbs should be potted as soon as they can be procured from the nurseryman. Presuming that at least part of the Roman Hyacinths and Paper-White Narcissi are potted up, the next bulbs to pot should be Tulips Van Thol, Mon Tresor, Yellow Prince, Prince of Austria and Rose Gris-de-Lin; Narcissi Golden Spur, Double Van Sion, princeps and Poeticus ornatus.

Chrysanthemums.—By this date most of the buds of the large-flowering varieties will have been taken, and the plants will need a good deal of looking after in respect to water and manure, the latter being given at least twice a week.

Top-Dressing.—As an inducement to keep the roots active, a top-dressing of loam, well-rotted manure and a little artificial manure should be given the plants, just sprinkling a handful or two over the surface of each pot and watering it in with a coarse rose. This may be repeated once or twice before the plants are placed indoors, and helps to sustain them in no uncertain manner.

Nerines.—Any plants that require potting may be done now, before they commence to throw up their flower-spikes, and these plants certainly look best when one or two bulbs are cultivated in a small pot. Loam and peat in about equal proportions, with a little charcoal and sand, seems to suit them well. After watering in, very little more water will be required till they commence making new roots, which they will soon do if placed in a house not too dry.

The Vegetable Garden.

Tomatoes.—Where these are not ripening as fast as one would like, the foliage may be partially removed; but if this is done, no more water should be given, or it may tend to crack the ripening fruit. To avoid this, the fruit should be gathered as soon as it commences to show colour, and it stored as advised in a previous calendar, it will be found to colour well.

Marrows.—Many of the earlier-planted Marrows will by this time have finished fruiting. Later plants must be treated liberally, according to

the weather conditions, so that the crop may be prolonged as late as possible.

Gourds that are swelling on pergolas must be supported by soft string, or the heavier ones by webbing. Keep the growing points tied in regularly, though it will be found that after about this date growth will be less rapid than heretofore. Mildew may prove a trouble to the plants, and, where it appears, either dust with sulphur or spray with one or other of the advertised fungicides.

Celery.—The earliest rows should have the earthing completed, as in most establishments good, crisp Celery is in demand by the end of September. After a thorough good watering and feeding of the later rows, earthing may be commenced, taking every care to get all decaying leaves and side shoots removed before pulling the soil up to the plants; and though the soil must be made firm at the base, it is necessary to leave the top free, so that the centre of the plant may come up freely, at least till the last earthing takes place.

Fruits Under Glass.

Late Grapes.—It is still not too late to feed very late Grapes, and I have seen excellent results where the Vines have been given a light dressing or two of nitrate of soda. It certainly helps them along wonderfully, though the danger lies in giving them an overdose, especially if the skins have been allowed to get tough through a none too generous treatment.

Hardy Fruit.

Summer Pruning.—Where, through stress of work, this has not been completed, every effort should be made to finish it off at once, so that the fruit may have the full benefit of light and sun during the few remaining weeks the fruit is on the trees, to say nothing of the extra size attained by the fruit when the sap has been diverted from the wood to it.

Black Currants.—After the fruit is gathered, the bushes may have the whole or part of the old fruiting branches removed; this will let light and air into the young growths, and a better crop of fruit may be looked forward to next year than when all of the wood is allowed to remain till the winter or spring.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Japanese Irises.—These are never happier than when treated as water-side plants, but such treatment is not absolutely necessary. In common with many of the genus having rhizomes, they enjoy a good baking towards the end of the season, and it has been found a good plan to go over the plants about this time and with a fork gently raise the roots slightly above the ground-level, treading them into position again about the end of September.

The Bulb Order.—As the bulb lists are all to hand, there is nothing to be gained, but rather the risk of loss, by delay in placing orders. Everyone should invest in some Tulips. Those who wish for an early display must invest in the early section, in which the following can be recommended; Crimsons and scarlets—Belle Alliance, Carmine Brilliant, Fireflame, Scarlet Pottebakker, Prince of Austria, Rembrandt and Vermilion Brilliant. Yellows—Canary Bird, Chrysolora, Golden Queen, Yellow Pottebakker and Prince de Ligny. Pinks—Couleur Ponceau, Proserpine, Rose Gris-de-Lin and Wapen Van Leiden. Odd colours—Duchesse de Parme, Keizerskroon and Thomas Moore. Whites (which are not much wanted)—Pottebakker White, White Pigeon and White Swan. Good May-flowering or Cottage varieties at easy prices are Blushing Bride (Shandon Bells), Bouton d'Or, gencieriana major, Golden Crown, macrospella, Picotee and The Fawn. For richness of colour and general excellence, however, the Darwins are unequalled.

The Rose Garden.

Cuttings.—With the exception of the ramblers, few Roses are now grown on their own roots. The Hybrid Perpetuals, ramblers in general and what are generally known as garden Roses can

all be readily propagated by cuttings in the open border, and from now onwards until the end of September is the best time to carry out the work. The cuttings of half-ripened wood, not too gross, should be made about nine inches long, and should be taken with a beel. Prepare in the ordinary way with a sharp knife, and insert about six inches deep in sandy soil, pressed firm. Water well, and if the border is not shady, shade for a week or two.

The Rock Garden.

Potting Off Cuttings.—Cuttings as they become rooted should be potted off into small pots, either to be planted in autumn or spring. Keep them in a close frame till they take to their pots, after which gradually mure to the open air when the weather is at all good.

Primula littoniana.—Those who have not yet included this lovely Primula among their collection, I would advise to do so. I saw it in grand form the other week among Mrs. de Pree's fine collection at Saughton House, Corstorphine.

Plants Under Glass.

Hyacinths.—The orders for these must now be placed, as the best bulbs are not usually kept till the last. The following are a few trustworthy varieties: Blues—Blue Baron Van Tuyll, Czar Peter, Grand Lilius, Grand Maître and King of the Blues. Reds and pinks—Amy, General Pélissier, Gertrude, Lady Derby, Norma and Queen Wilhelmina Whites—Baron Van Tuyll, La Candeur, La Grandesse, Mr. Pimmsell and Snowball.

Tulips.—As these are largely grown for cutting, a few good varieties in quantity are all that is required for the purpose. The following can be recommended: Scarlets—Belle Alliance and Carmine Brilliant. Crimsons—Rembrandt and Crimson King. Yellows—Chrysolora and Yellow Prince. Pinks—Rose Gris-de-Lin and Couleur Ponceau. Miscellaneous—Prince of Austria, Thomas Moore and Keizerskroon.

Daffodils.—Whether for cutting or for conservatory decoration, these are highly decorative. As with the other classes of bulbs, I only indicate varieties which are within the reach of all. Golden Spur, for a first batch; Emperor, Empress, Mme. de Graaff, Mme. Plomp, Glory of Leiden, princeps, Telamonius Van Sion, Barri conspicuus, Sir Watkin and Poeticus ornatus. The Polyanthus Narcissus and Poetaz hybrids are also worthy of attention.

Fruits Under Glass.

Late Tomatoes.—If sufficient fruits are set, stop the leading shoots and also all laterals. Defoliation is not to be recommended, but the fruits should have all the available light possible.

Late Melons.—These must have close attention, and, as the solar heat declines, more firming will be required, especially on wet or dull days. Pinch away all superfluous shoots, but expose as much foliage to the full light as possible, or the swelling of the fruits may be arrested. Lack of sufficient water at the root means undersized, inferior fruit.

The Hardy Fruit Garden.

Storing Nets.—As nets go out of use they should be bundled up and stored for the winter, but care should be taken that they are thoroughly dry before being stored.

Strawberries.—If the weather continues dry for any length of time, newly-planted Strawberries should be well watered, as their roots have not yet penetrated far into the soil. Any plantations of old plants to be retained for another year should be cleared of runners and have the Dutch hoe run through them. Take runners for spring planting and plant thickly in nursery lines, placing some flaky leaf-mould among the roots.

The Vegetable Garden.

Spring Cabbages.—These are a valuable asset in spring, and a good plantation should be made in the first week of September; meanwhile, the quarter should be prepared for them. A good plan is to plant after early Potatoes. Good farm-yard manure suits Cabbages very well, but it is not desirable to manure the crop too liberally at this season. When digging for the crop, one spade deep will be quite sufficient.

Leeks.—If good crops are expected, Leeks must receive liberal treatment, and a dressing of old fowl-manure or soot at the present time will have a magical effect.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PINCHING SWEET PEAS (J. C.).—If the seedling Sweet Peas do not break naturally from the base before they are 2 inches high, pinch out the point. You can then take up one, two or three stems at discretion. Your soil mixture is excellent, and should be prepared in the autumn.

IRISES DISEASED (Mrs. H.).—The Irises are attacked by the Iris leaf-spot fungus (*Heterosporium gracile*). Spraying does little to check the disease, but the best treatment is to give the ground about the plants a thorough dressing of lime in autumn after moving all the dead and affected foliage.

PAMPAS GRASS (W. H. C.).—It would have been better had you mixed about one-half of light loam, together with some old mortar rubble, with the soil for the Pampas Grass. It is possible, too, that the plant gets much too dry at the roots in spite of your waterings, and moisture during growth is essential to success. You might also try frequent doses of liquid manure.

IRIS STYLOSA AND AZALEA MOLLIS (Stoke Farming).—The best time to remove and replant *Iris stylosa* is in March and April, when the plants should also be divided. A sunny and well-drained spot, with rather light soil freely mixed with lime rubble or the like, is very desirable. Firm planting without burying the rhizome (rootstock) is essential. The *Azalea mollis* would be best planted during September or October.

CLIMBING PLANT TO COVER WIRE-NETTING (Devon).—The most likely climbing plant to succeed in the position you describe is the common wild Clematis (*C. Vitalba*). Although less beautiful than many of the garden kinds, it has the advantage of being vigorous and forming luxuriant growth. There is little doubt but that this plant will succeed and give slight trouble other than an annual pruning in spring to keep it within bounds.

A SWEET PEA SPORT (G. F. F.).—We do not like to say that this freak Sweet Pea is a throw-back to "early days," for what the origin of the Sweet Pea was before the wild type, *Lathyrus odoratus*, was evolved no one knows. The Sweet Pea is abnormal in several ways, but particularly in the very large keel and in the divided standard, which also bears outgrowths, called by teratologists eanions. The texture is similar to that of many other Sweet Peas now on the market.

SALPIGLOSSIS FAILING (M. J. P.).—There is no sign whatever on the *Salpiglossis* of the attack of any fungus. It seems probable that your soil is not in a good condition for maintaining a proper water supply, and these *Salpiglossis* plants, which, at the best of times, do not take very kindly to transplanting, are suffering mainly from this cause. Lime is sure to improve the texture of your soil, and it would be best to dig in powdered quicklime in autumn, allowing from four to six weeks to elapse before planting perennials on the part treated.

"STREAK" IN SWEET PEAS (G. M. I.).—The root of the Sweet Pea sent is affected by the fungus *Thielavia basicola*, causing root-rot, and the stem is affected by the trouble known as "streak." The "streak" in the stem has been attributed to the attack of bacteria, but the point is not clearly settled whether it is not rather the result of a combination of attacks. In any case the root-rot is a serious trouble and is usually associated with wrong soil conditions, such as too heavy manuring, over-watering and the like. Did the roots get away well from the cardboard pots in which the plants were planted?

LILIES, GENTIANS, AND OTHER QUESTIONS (Ignoramus).—The solution of the Lily problem is, most probably, that one bulb has made plenty of both new basal and stem roots and that the other has not. The Gentians named are best raised from seeds sown as soon as ripe. The *Eucomis* will flower in due course when it has gathered strength. Put it into a 7-inch pot. You do not say to what *Zephyranthes* you refer. The flowering is usually the outcome of strength of bulb. The *Linum* generally opens its flowers towards the evening. *Gentiana cruciata* is one of the strongest growers of this remarkable family, and usually succeeds well in most deep, well-drained soils. Possibly a few applications of water would assist the development of the spike and flower-buds, unless the latter are blind owing to the excessive drought

experienced a few weeks since. If this be so, the dried-up condition of the buds should reveal it upon close examination.

SWEET PEAS FAILING (Constant Subscriber).—The use of superphosphate and potash to the soil will do much good, provided it is commenced early enough; but if the plants are attacked already, little can be expected from that treatment. There is a fungus, a species of *Fusarium*, at the root of the Pea, bringing about root-rot, and this is likely to attack Peas if the soil has been used for growing Peas in before. Instead of making trenches, have the soil in which the Peas are intended to be grown treated all over alike, and do not use too much manure nor let it be put in layers. Have it thoroughly mixed with the soil all through.

CHRISTMAS ROSES (S. W.).—The essentials to the successful cultivation of the Christmas Rose are August or September planting, a prepared soil depth of at least 2½ feet accompanied by good drainage, and healthy, vigorous examples of three to five crowns with equally vigorous leafage. So far as position is concerned, a partially-shaded one is best, one backed by Hollies at a few feet distant or receiving the shelter afforded by more distant trees. Big clumps of these plants should never be planted, while equally useless are ballus examples which are but feebly rooted. If in your district you are close upon a chalk subsoil, special soil provision would have to be made. It is difficult for us to recommend a place to get such things, though, if you are planting largely, the better way would be to invite samples from some of the leading dealers in hardy plants, not forgetting the Scottish growers, whose stocks of hardy plants are usually of a good type.

KEEPING VIOLAS AND PANSIES (M. E. W.).—You might certainly lift these and give them the protection of the wall you refer to, planting them, if possible, in rather light soil. A month prior to lifting you should prune the plants, the old flowering branches more particularly, to within 2 inches of the soil, thus giving scope for the younger shoots, which will presently appear rather freely at the centre of the plants. If, when planted, you filter in some light soil among these younger shoots, they will, before spring, give you excellent material for replanting. It is just possible that some of the earliest-made shoots may require stopping. The best way of keeping both these is to root cuttings each year in September following the cutting-down process already given. Any improvised frame would do for the purpose. The perennial Mallow, *Malva moschata* and its variety *alba*, would be most likely to do with you, as the latter is one of the most desirable of border plants. Plant in early September.

TREES AND SHRUBS.

ABNORMAL GROWTH ON WILLOW (J. B.).—The abnormal growth on Willow sent for examination is due to irritation brought about by a minute insect known as *Eriophyes triadatus*, and the growth may be compared in character to the so-called Witches' Brooms frequently found on trees. This particular type of growth has been very prevalent in some districts during the last few years, particularly in the neighbourhood of Hampstead Heath in North London. It cannot be said to have serious consequences on the trees on which it occurs, although it is somewhat of an eyesore.

CRATÆGUS PYRACANTHA NOT FRUITING (E. A. P.).—This shrub should not be pruned in early spring, as any growths cut out then would most probably produce flowers. Whatever pruning is contemplated should be taken in hand after flowering; you would then leave all branches bearing fruits. Being only about six feet high, your bushes are young and growing freely. They will bear fruit more freely when 12 feet to 20 feet high. *Saxifraga hypnoides* forms an evergreen carpet, and should make a very serviceable plant for the purpose you mention.

CLEMATIS FAILING (A. H.).—Your complaint with respect to Clematis plants suddenly collapsing is, unfortunately, a common failing. Various reasons have been put forward as the cause. The great majority of Clematises are grafted, and it may be that the union is a bad one, though apparently satisfactory for some years. Clematis plants with the lower part of the stem exposed to the sun frequently fail; apparently the sun cracks the stem and causes death above. There is a good deal to be said for this reason, as the plants often push out quite healthy growths below where the stem is affected. The remedy is to plant the varieties of Clematis Jackmanii and others which fall in this way among shrubs or on a western aspect where the fierce rays of the sun cannot reach the stems.

SHRUBS FOR DRY BORDER (M. A. M.).—Flowering shrubs that would succeed in a very dry border are *Berberis vulgaris*, *Caryopteris Mastacanthus*, *Cistus* of sorts, *Coleautes* of sorts, *Hedysarum multijugum*, *Helianthemum* of sorts, *Hibiscus syriacus* in variety, *Hypericum calycinum*, *Lavandula spica*, *Ononis fruticosa*, *Perowskia atriplicifolia*, *Phlomis fruticosa*, *Potentilla fruticosa*, *P. Veitchii*, *Rubus fruticosus alba plena*, *R. f. roseo plena*, *Spartium junceum* and *Ulex europæus flore plena*. If your border is not too dry for the subjects named by you, there are others that may be safely planted therein, such as *Abelia repens*, *Cydonia japonica*, *Desmodium penduliflorum*, *Deutzia crenata flore plena*, *Fuchsia (hardy)*, *Genistas* of sorts, *Ludwigia gerardiæna*, *Lonicera Maackii*, *Philadelphus* of sorts, *Rhodotypos kerrioides*, *Rubus deliciosus* and *Weigela* in variety.

FUCHSIA RICCARTONI AND LILY (R. D.).—In all probability the *Fuchsia* has occupied its position too long and the soil has become exhausted. In these circumstances the only remedy would be to remove the plant to a fresh site in the spring of 1914, well enriching the soil and dividing up the old specimen before replanting. It may be, too,

that the present position is sufficiently warm, and if a summer one could be provided, so much the better. We are afraid it will not pay you for your trouble to attempt to keep the Lilies, as they rarely do much in the way of flowering the second year. Moreover, flowering bulbs are to be had so cheaply in the early months of the year, or even during the ensuing autumn. If, however, you still have a desire to try, the better way would be to lift the bulbs from the soil when flowering is past, and to put them in a little rather dry soil or Cocoanut fibre in a box, placing them in a cellar for the winter months.

ROSE GARDEN.

ROSE JULIET WITH DIVIDED BLOOMS (E. G. F.).—It is characteristic of the Rose. You must feed the plant well, prune fairly hard, and you will get some good blooms.

TRANSPLANTING LARGE RAMBLERS (E. M. B.).—You could transplant these in November, but you need to cut them back severely, and we doubt if they would be worth the trouble, seeing that you can obtain young plants so cheaply. It would take at least two years for the ramblers to recover from the transplanting, and by that time young plants would have made almost as much growth.

CLIMBING ROSE (L. M. S.).—*Hawatha* is quite late, and you could not have anything of this class much later. Climbing Mrs. Cutbush is perpetual flowering, and also *Jean Girin*. For a small pergoia we would suggest *Grüss an Tepitz*, Climbing *Cranioica Supérieure* and *Florence Haswell Veitch*. These are perpetual flowering and should meet your wishes. A late vigorous purple Clematis is *C. Jackmanii*.

BRIAR HEDGE (Chester).—If your Sweet Briar hedge is very rough and untidy, you may cut it back a little at once, but it would be better to leave the general cutting back until the end of March next year. You may then cut it back into fairly old wood. Remove some of the soil about the roots during the winter, and replace it with a mixture of well-rotted manure and good loam. Then, towards the end of May next year, give the ground a surface-dressing of well-decayed manure.

CLIMBING ROSES AND CLEMATISES TO COVER A SOUTH WALL (Anthony).—The following Roses are likely to succeed and give good results: *Gloire de Dijon*, *William Allen Richardson*, *Ards Pillar*, Climbing *Sony*, *de la Malmaison*, *Longworth Rambler*, *Cheshunt Hybrid*, *Grüss an Tepitz*, Climbing *Frau Karl Druschki*, *Alberic Barbier*, *Tea Rambler*, *Lyon Rambler*, *Florence H. Veitch*, *Hélène Granger* and *Elise Robichon*. The following kinds of Clematis are well worth planting. Some shade should be afforded for the roots, *C. montana*, *C. m. rubens*, *C. Lady Caroline Nevill*, *C. La France*, *C. Mme. Edouard André*, *C. Jackmanii superba* and *C. lanuginosa*.

ROSE NIPHETOS FAILING (Jane).—The plant is evidently in a weakly condition, owing, doubtless, to lack of nourishment. Such a free-growing Rose as this should receive liquid manure twice a week from the time it commences to show its buds. This not only assists the buds, but also the subsequent growth, which lays the foundation for a healthy tree. Fork up the soil now if the bush is planted out, and give some liquid cow-manure, previously watering the soil with plain water. If in a pot, the same treatment should be given. The curled leaves are due to a form of mildew, probably arising from drought at the roots. Cut away such growth now, and give the plant a good spraying every other day with *Jeyes' Horticultural Wash*.

ROSES THROWING BLIND WOOD (Ardeen).—This defect is peculiar to some varieties, but is most generally attributed to want of ripening of the old wood. You would do well to replot your Roses at once, and stand them outdoors on a bed of ashes in full sun. Be careful not to over-water them, and keep all flower-buds pinched off. In October give them a good drying off by laying the pots on their sides for about two weeks; then remove to a cold frame until you wish to place them in the forcing-house. *J. B. Clark* is a bad Rose for splitting. It must be well disbudded and its shoots well thinned out. Possibly you would find standards to yield the best blooms under this treatment. When disbudding, always select the most perfect bud to retain.

ROSE FOLIAGE BLIGHTED (E. A. D. G. V.).—The Roses must be in a very bad condition. They have the black and also the white mildew. You had better have a lot of the very worst foliage cut away and burnt; then give the plants a thorough good spraying with a solution of carbolic soap, at the rate of about four ounces to a gallon of water. Or another good recipe would be: Half a pound of lime, lib. of sulphur, and half a pound of soft soap, all boiled together in a gallon of water. Use half a pint of this liquid to two gallons of soft water. Unless the tree is a very old one, we advise you to dig it up and burn it, rather than waste time in trying to cure the blight, as it has obtained such a strong hold of the foliage and may infect the healthy trees. Probably this particular tree is in a bad state at the roots, which has checked its growth; and when growth is arrested, then is the time that blights obtain a strong hold of the plant.

THE GREENHOUSE.

ORCHID LEAVES TURNING BROWN (C. Mayhew).—You do not give us sufficient information concerning the treatment given to the Orchids of which leaves were enclosed. However willing to oblige our readers, we are greatly handicapped by this lack of knowledge on important points. We should say that an excess of atmospheric moisture, combined with a low temperature, is at the root of the trouble; but there are other possible causes.

GLOXINIAS (*Mrs. G. F. C.*).—There are several possible reasons for the unsatisfactory condition of your Gloxinias. In the first place, as the surface of the pots is rather moss-grown, it would indicate that the plants are potted in unsuitable soil, or that drainage is at fault. Next, the small hothouse in which they were grown was probably too hot for them, and the change into a cooler structure too drastic. Gloxinias are very often grown in too much heat, with decidedly unsatisfactory results. With regard to manure-water, the time to apply it will depend entirely upon the condition of the plants. It must only be used when the roots are in a good, healthy state, so that the plant is able to assimilate the food, as, if it is not in this condition, stimulants of any kind will do far more harm than good. In order to give your plants the best chance for another season, they should be kept in the greenhouse, where they are shaded from the full rays of the sun. After the flowers are past, the plants should be watered as before (if they show signs of going to rest by the leaves turning yellow, when less moisture will be required). When quite dormant, water may be discontinued altogether. They may be wintered in the pots they have grown in, keeping them quite dry in a temperature of 50° to 60°. In spring shake them clear of the old soil and re-pot in a mixture of loam, leaf-mould and sand, where in a minimum temperature of 55° they will soon start into growth. They will not need much water till the leaves appear.

FRUIT GARDEN.

NECTARINES CRACKING (*W. H. T.*).—Probably the atmosphere of the house is too humid and moist. Give abundance of air day and night while the weather is fine. Giving the tree a good soaking of water at the roots a short time previously would also cause cracking. In watering your trees you should so contrive to give them a good soaking before the second swelling is too far advanced to cause this cracking.

GUMMING IN PEACH TREES (*B. A. I.*).—Allowing the trees to make gross and ill-ripened shoots, especially if they are injured by bruising the bark, is one of the chief causes of gumming. Check the growth by root-pruning, training the shoots carefully. Allowing the roots to run too deeply in stiff soil, thus preventing maturity of growth, is also a cause. Lift the trees in bad cases, replanting nearer the surface. Training the branches thinly is an excellent remedy.

SILVER-LEAF IN FRUIT TREES (*B. A. I.*).—Sulphate of iron in powdered crystal form mixed with the soil in March is an excellent remedy for silver-leaf. For a tree ten years old use 6lb., and so on according to the age. Take out a trench, 1 foot deep, from the stem of the tree, 4 feet wide on each side of the stem, mix the sulphate evenly among the soil and roots as the digging proceeds, and, if the roots are not found at that depth, go deeper, bringing them nearer the surface.

APPLE TREES INFESTED WITH INSECT PESTS (*Greystoke*).—Spray your trees with the following winter wash. The best time to do this is in February, after the trees have been pruned. Iron sulphate, half a pound; lime, quarter of a pound; caustic soda, 2lb.; paraffin, five pints; and water, ten gallons. Dissolve the copper sulphate in eight or nine gallons of water. Slake the lime in water and add to the dissolved copper sulphate, running it through a fine sieve. Add the paraffin and keep it stirred, and then add the caustic soda and water to bring the whole up to ten gallons. Spray your trees again just before the flower-buds burst open with Abol, a preparation which is most effective in clearing fruit trees of all manner of pests and blight, and which can do no harm to the trees or tenderest flowers. Abol may be bought, with instructions how to use it, from any nurserymen or seed merchants advertising with us.

GRAPES MILDEWED (*J. F. B., Norfolk*).—Mildew always seems to exist in the air, ready and waiting for favourable atmospheric conditions and an opportunity to seize its victims, the Vine under class being one of its favourites. To know what are the conditions which invite and favour its attack is the surest way of frustrating its intentions. The atmospheric conditions which mostly favour an attack are a low, damp night temperature with a sudden rise by sun-heat on a sunny morning, and afterwards the admittance of too much cold air to bring down this high temperature. The foliage of the Vine is very tender at this time, and highly sensitive to sudden changes in temperatures, which cause a chill and create the conditions which favour an attack by this pest. The remedy lies in continuing to have a gentle heat in the pipes, especially at night, until the Grapes have done stoning. The foliage and berries will then have become riper and harder, and better able to protect themselves against its attack. With slight heat in the pipes at night, air must be given in moderation, both front and back; a free circulation will then be secured and the atmosphere rendered buoyant, fairly warm and free from the defects noticed above. The viney having air on all night, the temperature will rise gradually in the early morning, and there will not be the necessity to open the ventilators too wide at any one time. Heat in the pipes will not be so necessary during the day, unless the weather is cold and damp, when a little should always be applied in the early stages of the Vine's growth.

KITCHEN GARDEN.

SPRAYING POTATOES (*T. V. H.*).—For spraying garden crops of Potatoes the Vermorel Knapsack Pump is an effective, easily-worked and handy machine. It is not expensive, and may be had from any horticultural sundries-man advertising in THE GARDEN.

PEAS GOING WRONG (*E. C.*).—The Peas appear to be attacked by a newly-described bacterial disease, the full

history of which is at present unknown. There is also some suggestion of root-rot; but as the disease has not yet been fully worked out, it is impossible to give any remedial measures. It would be well to grow the plants next season on soil which has not been previously used for growing Peas.

CELERY ATTACKED BY FUNGUS (*J. P.*).—It would have been well to have commenced the treatment of the Celery plants for the Septoria attack earlier than this, as it is a disease which, when once it has gained a hold, is extremely difficult to overtake. It would be well to spray with Bordeaux mixture from now onwards at intervals of three weeks. Bordeaux mixture is made by dissolving in separate wooden vessels, in soft water, 6lb. of copper sulphate (98 per cent. purity) and slaking 4lb. of best quick (or unslaked) lime, each of them requiring about five gallons of water. When the copper sulphate is dissolved and the lime thoroughly slaked and cold, pour the two together and dilute to forty gallons with water. Apply as a very fine spray, covering the plants completely with it.

BEETROOT DOING BADLY (*Ere*).—Seeing that you buy your seed from the seed merchants mentioned, there can be no question of its purity and power of growth. Land should not be freshly manured for the growth of Beet; instead it should be grown in soil which has been liberally manured for a crop the previous year, say, Potatoes or Peas. Dig the soil deeply in early spring and prepare for sowing on May 1. If the soil is heavy, place a layer, half an inch deep, of old, fine potting soil at the bottom of the drill; this will help the seed to vegetate quickly. The seedlings come up quickly at this time, and the little plants are often devoured by slugs or minute flies before they are seen by the naked eye. Soot and lime in equal quantities should be scattered lightly over the rows in the course of a fine day after the seed is sown, and every eight or nine days afterwards until the young plants are an inch or so out of the ground and free from further attack.

FEEDING VEGETABLE MARROWS BY ARTIFICIAL MEANS (*Barker*).—Our correspondent says: "I have heard it is possible to feed Vegetable Marrows by, I think, piercing the stem and placing through it a horsehair with its ends in a sugar solution, or something to that effect." Nature is so long-suffering that she will bear any torture inflicted upon her, seemingly, with meekness and resignation; but in the long run she is bound to have her revenge. And so it would be in this case. The tearing and bruising of the tissues of the stem by the act of piercing through it could only result in destroying many of the sap-vessels whose office it is to supply the plant with nutriment for its life and growth. A plant can only feed through its roots and some constituents which its foliage absorbs from the air. For the grubs infesting Carrots, Cauliflower and even eating the roots of the Parsley, try what watering with lime and soot water will do. To eight gallons of soft water add half a gallon of fresh lime and a quart of soot. Well mix and churn with the water at the time the lime and soot are placed in the water. Let the mixture stand for twenty-four hours, and water with clear water only, without the sediment. If this does not answer, the most effectual way is to break up (with a hand-fork or trowel) the surface soil round the collar of the plant until the surface roots are reached, and then to search for the grubs. They are generally found near the surface, and the plants are often saved in this way.

MISCELLANEOUS.

ANALYSING WATER (*C. Butler*).—You should get the water analysed by a professional analyst. Probably it could be done at the East Anglian Institute of Agriculture at Chelmsford for a small fee for the purpose mentioned. There are mineral springs in your neighbourhood, and the test to which you refer would not reveal any impurities injurious to plants, though it would be an indication of suitability or otherwise for human consumption.

SLUGS (*Chester*).—These have been a considerable source of trouble in some districts for the last eighteen months; it is thought by reason of the great amount of rain experienced last year. Some people trap them by placing lines of bran or sawdust about the ground, while others sow lime or soot over the ground. On any vacant ground it would be a good plan to apply a good dressing of soot and unslaked lime before digging it over. It would also be a good plan to surround beds of annuals with rings of soot, sawdust, or bran. Another plan for destroying slugs is to place slices of Turnip about on the ground. The slugs shelter beneath these, and may then be caught. They may also be searched for by the aid of a lantern during the early part of the night. The "V.T.H." Slug Trap, supplied by Mr. Vernon T. Hill, Mendip Nurseries, Langford, Somerset, is highly to be commended.

NAMES OF FRUIT.—*E. C.*—1, Lord Suffolk; 2, Ecklinville Seedling; 3, Cardinal; 4, Keswick Codlin; 5, Nelson's Codlin; 6, Tower of Glamis.

NAMES OF PLANTS.—*Interested*.—1, *Empetrum nigrum*; 2 and 4, *Apium nodiflorum*; 3, *Gnaphalium uliginosum*; 5, *Stachys Betonica*; 6, *Carduus crispus*; 7, *C. arvensis*; 8, *C. lanceolatus*; 9, *Senecio*; 10, *Hypericum perforatum*; 11 and 12, *H. hirsutum*.—*T. C.*—1, *Sedum sieboldii*; 2, *Othonna cernua*; 3, *Sedum sarmentosum variegatum*; 4, *Tolmiea Menziesii*; 5, *Ceratum Siliqua* (Carob Tree); 6, *Aspidium leptopus*; 7, *Sedum reflexum*.—*Woodman*.—*Rhus Cotinus* (Venetian Sumach) and *Hedera Helix chrysoylla*.—*D. A.*—1, *Pentstemon phoeniceum*; 2, *Linaria dalmatica*; 3, *Pentstemon barbatus*.—*J. S., County Durham*.—1, *Geranium pratense*; 2, *Alonosa Warszewiczii*.—*Hodgkinley*.—*Escalonia rubra*, *Rhamnus Frangula* (Berry-bearing Alder) and

Rhododendron viscosa variety.—*J. S., Hants*.—*Sisyrinchium striatum*.—*A. O., Suffolk*.—*Centranthus macrosporus*. It is an annual, native of Spain.—*J. B.*—*Roses*: 1, Captain Hayward; 2, White Pet; 3, Marquise de Siney; 4, Billiard at Barré; 5, A. K. Williams; 6, Baroness Rothschild.—*Lieutenant-Colonel H. F. D.*—We believe the Rose to be *Mrs. C. Curtis Harrison*.—*H. B., Birmingham*.—*Lychnis oculata*.

SOCIETIES.

PERTHSHIRE SWEET PEA SOCIETY.

The Perthshire Sweet Pea Society held its fourth annual show in the City Hall, Perth, on August 9. The Very Rev. Provost Smythe opened the show, the Earl and Countess of Kinnoull and Sir John and Lady Dewar being also on the platform. The show was the finest the society has ever held, and both quantity and quality showed an improvement on those of former years. A gold medal offered by the society, and open to the trade, for the best table of Sweet Peas was won by Messrs. Thyme and Son, Dundee, with a magnificent display. For the best twelve bunches of Sweet Peas, for which Sir John Dewar offered a gold medal, Mr. E. Cowdy, Belfast, was awarded the prize with a splendid lot of blooms. Another very successful competitor was Mr. J. Petrie, Crathes Castle, who won two silver medals, offered by the society for six bunches and for the same number of new Sweet Peas, besides a special for the most points won at the show. In the division for growers of from 15 yards to 20 yards, Mr. R. Duncan, Kemnay, Aberdeen, won the society's challenge cup for nine bunches, and also a medal for six bunches. The National Sweet Pea Society's medal for small growers was won by Mr. Glover, Colinton, Edinburg.

SCOTTISH HORTICULTURAL ASSOCIATION.

About ninety members of the Scottish Horticultural Association participated in the excursion to Carberry Tower, the seat of Lord Elphinstone, who had kindly invited the association to visit the gardens. On arrival, the members, who were accompanied by the president, Mr. David King, Osborne Nurseries, Edinburgh, were met by Mr. D. Kidd, the gardener, and by him conducted through the gardens and grounds. Much was observed to admire, and the party were highly pleased with the excellent order in which they found everything, both under glass and outside. Mr. Kidd is well known as one of the ablest of Scottish gardeners, and Carberry Tower Gardens were found full of interest. The herbaceous borders were very fine, and the Dutch garden, an old and striking feature of the place, was much admired for its quaintness and beauty. Roses were very fine indeed. The company was kindly entertained at tea by Lord and Lady Elphinstone, to whom, on the motion of the president, a hearty vote of thanks was accorded. A similar recognition was made of the courtesy and kindness of Mr. Kidd.

THE BRITISH PTERIDOLOGICAL SOCIETY.

This society as usual, held its annual meeting on August Bank Holiday, this time on the 4th, at Totnes, Devon, after a preliminary investigation of the locality as a promising Fern-hunting region by the hon. secretary, Mr. Charles T. Drury, and Mr. W. B. Cranfield, the treasurer, who found it all that could be desired as regards abundance of Ferns and of species. At the business meeting the balance-sheet and the membership were found to be highly satisfactory, no fewer than 160 members having replaced the original score existing at the time of the, so to speak, reconstruction of the society and the establishment of the *British Fern Gazette*, edited by Mr. Drury, which was at once recognised as deserving of the support of all lovers of British Ferns in their beautiful and multifarious characters.

The Seven Stars Hotel was fixed as the meeting-place, and prior to and after the meeting the members present organised various hunting expeditions to Dartmoor and the surrounding district of South Devon, with very satisfactory results, although a two months' drought had played havoc with all the exposed Ferns, which in many places had been killed outright and in most presented a flaccid and shrivelled appearance, which utilised seriously against any recognition of varietal features. Notwithstanding, however, this handicap, a number of good varieties fell to the lot of the searchers, showing that Nature was still busy in producing sports, although one might imagine that the great number of such acquisitions by the coterie of old prospectors, with their sharp eyes, would have practically exhausted the chances of fresh discoveries. A number of very beautiful forms obtained by selective sowing were sent by absent members as a proof that in this direction also much had been, and was still being, done to improve, if possible, the original wild varieties through their capacity of further variation by their spores. From a patriotic point of view, therefore, the society, devoting itself purely to our native Ferns, has proved itself to be well worthy of support, and it is hoped that its membership will continue to increase in view of the fact that the quarterly issue of the *British Fern Gazette*, under the experienced editorship of the well-known expert, Mr. Charles T. Drury, V.M.H., F.L.S., fully repays the expenditure of the 5s. per annum (August to August), which secures its receipt and constitutes the subscriber a member of the large body of Fern enthusiasts, with which it brings him or her (for many members are ladies) into more or less direct contact. Mr. Drury is also the hon. secretary. His address is 11, Shaa Road, Acton, W., and he is always ready to send a specimen number of the *Gazette* to anyone contemplating membership.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Cutting Dead Wood from Trees.—Now will be found a good time for looking around trees and shrubs and cutting out all dead wood, particularly from deciduous ones, as it is not always an easy matter to detect the dead wood when the leaves are off; certainly not so easy as now. It is very important to put a coating of tar on each of the cuts afterwards to prevent disease getting into the wound.

Sowing Grass Seed. Bare spots on the lawns or grass paths should be pricked up with a fork, and grass seed sown. If preparation has been made for the making of lawns, the seed should be sown now, as much time is saved and better results are obtained than if left till the spring. Dull, showery weather is preferable, but if the weather should be very dry, a few waterings will greatly assist the seed to germinate quickly.

Root-Pruning Fruit Trees.—September is the best month for this operation, which generally throws into a fruiting state fruit trees which have either rooted into an uncongenial subsoil or are growing too much to wood. It is well only to attack one-half of the roots in a season. Keep about three feet clear of the stem, and be sure you get right under the tree. Trim all cut, bare roots with a sharp knife, and work in some maiden loam among them.

Sweet Pea Royal Rose.—For garden decoration and cutting, this is a delightful Sweet Pea. It is in the way of John Ingman, but the stock is more reliable, coming quite true, which, unfortunately, cannot be said of some of the seeds sold as John Ingman. The flowers are rich rose red, showing no trace of magenta, and nicely frilled. The plants are robust, autumn-sown seeds growing to feet high in the usual soil of a good herbaceous border. The later flowers maintain their size, colour and length of stalk better than many sorts.

Saxifraga florulenta.—Considerable interest was displayed in this curious species of Saxifraga, shown recently before the scientific committee of the Royal Horticultural Society by Mr. Chaplin of Great Anwell, Ware, in whose garden it had flowered. It was collected by him, and had apparently been growing in shade in cultivation, though it appears to grow alike in sun and shade in its home in the Maritime Alps, where it occurs at high altitudes. It has, perhaps, only once before flowered in this country, when it received a first-class certificate in June, 1872, being shown by Mr. Maw.

Honeysuckles as Bushes.—In a garden visited recently we noticed several extremely fine specimens of Honeysuckle. There were several varieties, some of the bushes being about nine feet high and more in diameter. They were profusely flowered, and, as the positions were open ones on the lawn, the plants drew the attention of visitors both on account of their size, quantity of blossom and delightful fragrance. It is not at all a difficult

matter to establish such bushes if they are given the support of a strong stake during the first three or four years.

A Blaze of Colour.—For some years now the flower-beds in the front of Buckingham Palace have been planted entirely with the rich-coloured Zonal Pelargonium Paul Crampel, and this season there is no exception to the rule. The flat, unbroken surface of the beds is, however, relieved by good-sized specimens of the same variety. The whole of the plants have done remarkably well this summer, and present such a blaze of colour as one rarely sees. It may be questioned whether this is the most suitable arrangement for the position, but there can be no doubt that as far as showiness is concerned it could not be surpassed.

Valuable Spring-flowering Plants.—There are several varieties of the well-known *Silene pendula* for making our gardens look gay in the late spring, of which *Silene pendula ruberrima* and *S. p. Snow King* are two of the best. As a groundwork for larger plants, an edging, or for massing in the borders, they are most valuable. Seeds should be sown now, and the seedlings will make good plants for putting out later. As the majority of *Silenes* suffer more from the damp during the winter than they do from the cold, it will be found advisable to sow them in sandy soil, and, if the ground is of a heavy and cold nature, to delay the transplanting till the early spring.

Transplanting the Christmas Rose.—Few flowers are more appreciated than the Christmas Roses (*Helleborus niger*), blooming as they do at a period of the year when almost all flowers are at rest. The plants thrive in almost any ordinary garden soil, but prefer a rich loam, with a moist, rather shady, perfectly-drained situation. Now will be found a good time to take up the large clumps and divide them. If this operation is left till later, the transplanting will check the blooming. They are excellent for growing in pots in the greenhouse if potted up now and placed in a frame, but they should not by any means be forced.

Early-flowering Chrysanthemums.—Those annuals and biennials that are now past should be removed from beds or borders and the gaps filled with early-flowering Chrysanthemums. These are not used to the extent that they should be for such a purpose, and many a bare spot could be made to look gay with these valuable plants. They can be grown with very little trouble in a piece of reserved ground, planting them out as space occurs. If care is taken, they can be transplanted without suffering in the least, even when in bloom; but it will be found advisable to cut round the plants with a spade about five inches or six inches from the stem, and give a good watering a day or so before transplanting. Should the weather be dry, the plants should be watered once or twice, giving an occasional syringing over the foliage.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Campanula Zoysii.—By way of experiment I have this year tried this plant both in sun and in semi-shade. While that with full exposure flowered earlier, I must give the palm to the plant in semi-shade, as it produced more numerous and finer flowers than the plant facing south-west. It is a quaint little plant which always interests visitors.—B., Weybridge.

Lilium pardalinum.—I bought one of these Lilies in 1910. The next year (1911) there was one head; this year (1913) there have been seven heads from 4 feet to 6 feet high with over sixty flowers. It is planted in a hot, damp corner, with the roots shaded by a large Rose bush, and it was a grand sight to see these brilliant flowers, a mass of scarlet and orange.—M. W. SUGDEN, Wells, Somerset.

Erica mediterranea hybrida.—Is it not yet possible to give this fine Heath another name than either this or *E. hybrida*, which, as you remark (issue August 16, page 407), may cause confusion? It is so distinct from *E. mediterranea* that it is a pity to attach the name of the latter to it at all. I cannot recollect having come across any authentic account of its origin. It is one of the most valuable of our hardy Heaths, and far and away more generally useful even than *E. mediterranea* itself.—S. A.

Is Rose Irish Elegance Free-Flowering?—During the present year this charming single Rose has been very freely used for table decorations at all the leading shows, and in most instances has secured the premier award. In discussing it some time ago with rosarian friends, I was, however, told none too gently that it was not a Rose for the garden, as it did not flower freely and its blooms were too fugacious. The latter statement one has, unfortunately, to agree with, but I think the accompanying photograph proves that it is free-flowering enough. The photograph depicts a part only of a bush, and was taken early in August, so that the flowers shown are the second crop. It would be interesting if other readers would give their opinions of the merits of this Rose for the garden.—A. B. FISSEX.

The Creeping Jenny.—In addition to the suggestions in your valuable little note in THE GARDEN of August 16, page 405, one may mention that the Creeping Jenny (*Lysimachia Nummularia*) is very useful for covering the margins of a pond, where it thrives splendidly. It is excellent for covering the surface of the soil occupied by early bulbs which love some moisture, and there the Creeping Jenny is much finer than when in a drier place. It is as good in sun as in shade. The golden-leaved variety looks especially bright, and some pieces on the margin of a little Water Lily pond are very pleasing from June onwards.—S. ARNOULT.

Campanula pusilla Miranda.—Some two or three years since I acquired a plant of this from

the Craven Nursery, and I am glad that I did so, as I think it the daintiest *Campanula* I have seen. It is of dwarf habit, only occupying a small space, with sweet, dome-shaped, pendent flowers of a grey blue colour, so produced as to be shown to the best advantage, and not crowded together like those on *Campanula pusilla* Miss Willmott. *Campanula pusilla* Miranda was, I believe, found by Mr. Reginald Farrer, and alpinists owe him a debt of gratitude for it. I had a good display of bloom on my plant in June, and now it is kindly flowering again.—W. A. BILNEY.

Outdoor Tomatoes.—To the interesting remarks made by a correspondent in the issue dated August 16, page 406, I should like to say a word in favour of the variety Sutton's Early Market

gathered along the banks of the River Tsar, where they grew of their own accord. How this happens it was explained—that the town sewage enters the river a little way below the city, and as at the time when the snow melts in the mountains the river carries a considerable flood-tide and overflows its banks, the Tomato seeds, which find their way into the river through the sewage canal, are, when the waters recede to the river bed, deposited and left to germinate along its banks and ripen their fruits in favourable seasons.—E. HEINRICH.

Wahlenbergia vincaeflora.—It is gratifying to see your appreciation of this plant, as it is, in my opinion, one of the best recent introductions in the way of an alpine. I have planted it in a south-west aspect, and it has been full of flower for several weeks past, regardless of the drought we have had to endure so long. All flowers (especially Roses) are much smaller this summer than usual on this red-hot sandy soil. Possibly in a normal summer the flowers on this plant would be larger than now.—B., Weybridge.

Scentless Musk.—For several weeks past I have read with interest the notes on scentless Musk. I have three pots of Musk, *Mimulus moschatus*, and have had them by me, as far as I can remember, nine years, and potted them up every year in the spring. These plants retain as good a scent now as they had when I first purchased them. The only treatment I give is the ordinary one. I keep them in a cool greenhouse in the winter months, and outside on shelves in the summer. The scent is beautiful, and I would be only too pleased to send a cutting to readers who wish for it.—F. M., Surrey.

— For some years past my small-flowered yellow Musk has been quite scentless, and I do not care to keep it, but it continues to grow in a pot with a Date Palm, and if it is nothing else, it looks pretty and green.—M. W. S., Somerset.

— If you do not consider the subject is worn out, I regretfully add my testimony to the fact that Musk has ceased to contribute any scent at all to my garden. I have been puzzling over it and observing with interest the remarks on this subject in your valuable paper.—M. SYBIL WHITEFOORD, East Brook, Wokingham.

— I asked an old and observant jobbing gardener the other day: "Do you believe that Musk has lost its smell?" The answer came,

ROSE IRISH ELEGANCE IN A READER'S GARDEN.

for outdoor culture. It is especially valuable for the purpose, being early and setting its fruits very freely. They are of medium size, smooth, rich red in colour, and six to twelve or more are borne in a cluster. In a cold frame, on a south wall and in the open, the results are equally satisfactory.—A. O.

— When writing my last note on these (THE GARDEN, August 16) I quite forgot to mention a very interesting statement which appeared in the *Minchner Neueste Nachrichten* at the end of the hot season of 1911. It was there stated that poor people were regularly seen to carry to town baskets full of ripe Tomatoes, and on enquiry it was found that these were being

prompt and decisive: "Noa, I doan't! It'll smell fast enough when t' weather's soft and warm, but never in a cold north wind like this year." And I think, in the main, my opinion is like his. Musk never did smell late on in the season, and it needs a moist, still air, not too cold, to give off its fullest perfume in June, just when the first flowers are opening. There may, of course, be scentless seedling forms that have ousted the type in Southern gardens, but the sweet-scented Musk is still to be found in Yorkshire (and elsewhere, too), I have no doubt. This season, with its cold, drying, "Polar-current" winds, has prevented the Musk from giving off its perfume, and now it is too late for this year at any rate.—EDWARD H. WOODALL.

HERBACEOUS BORDERS IN THE NORTH CANONRY GARDEN,
SALISBURY CLOSE.

Salvia turkestanica.—I saw this *Salvia* for the first time the other day in the gardens of Mr. Alexander Porter, florist, Davidson's Mains, Midlothian, and was struck with its suitability for the wild garden. The plants had not been very liberally treated, but stood about three and a-half feet high. I fancy that with good cultivation it would attain a height of 5 feet. The flowers are pure white, and the bracts retain their whiteness long after the flowers are over. The leaves on the plants I saw were about six inches by nine inches.—CHARLES COMFORT.

The St. John's Wort.—Few kinds of plants of low growth excel this as a dry border subject. A steep bank not more than 100 yards from the sea in a Southern town is beautifully covered with the St. John's Wort, which not only possesses luxuriant foliage, but bears flowers profusely. In another garden I find the plant equally successful on the level ground, also in a sandy rooting medium. As undergrowth to tall shrubs and trees it is thriving, even though the trees rob the plants of much nourishment. There are few flowering shrubs, if any, that will succeed so well as the St. John's Wort under the shade of trees. Readers who experience any difficulty in getting plants established in such positions may make a note of the one here referred to.—G., Bournemouth.

Zonal Pelargonium Maxime Kovalevsky.—This *Pelargonium*, which has been before now referred to in THE GARDEN, forms, from the distinct tone of its blossoms, quite an uncommon feature among the different varieties bedded out at Hampton Court. The actual colour, a kind of soft orange, is difficult to describe, and at a little distance one would scarcely take it to be a *Pelargonium*. At Hampton Court it has a bed to itself, with the exception of an edging of variegated *Holcus* and a few dot plants of *Leucophyta Brownii*. This distinct *Pelargonium* was raised by M. Lemoine of Nancy, and distributed about half-a-dozen years ago.

Lilium chalcedonicum.—Many good examples of this delightful Lily were noted at the Royal Horticultural Hall recently. It is a member of the Turk's-cap or Martagon section, though the leaves are not arranged in whorls as in the true Martagons. The flowering season of *L. chalcedonicum* is, as a rule, towards the latter part of July and the first half of August, though, of course, it varies somewhat according to season and locality. It grows generally from 3 feet to 4 feet in height, the rather small flowers being gracefully recurved, of a thick, wax-like texture and a sealing-wax red colour. From their substance the blooms retain their freshness longer than those of many other Lilies. The Scarlet Martagon, as *L. chalcedonicum* is popularly termed, needs a fairly holding loam, and is seen at its best when fully established. Apart from any other consideration, it is particularly interesting as being one of the supposed parents of the charming *L. testaceum*.—H. P.

FORTHCOMING EVENTS.

September 2.—Scottish Horticultural Association's Meeting. Flower Show at Bicester.

September 3.—Flower Shows at Glasgow (two days), Alnwick, and Preston (three days).

September 4.—Flower Shows at Peterborough and Kilkenny.

September 6.—Flower Shows at Mauchline and Kirkby Stephen. Société Française d'Horticulture de Londres Meeting.

THE FLOWER GARDEN.

HARDY ANNUALS FOR AUTUMN SOWING.

(Continued from page 420.)

Time to Sow.—This is a subject that is too often passed over and lightly thought of. When the right time for sowing comes along, the ground is not ready or other work is pressing. The proper time for sowing is from mid-August till about the third week in September. Occasionally a very late sowing is successful when we have a mild November, or even until Christmas; but it is not worth the risk. Sow early and get good, sturdy plants, not necessarily tall, which will stand the winter. If the flowering position is not ready, sow on the reserve border at the right time and transplant later. Take as a guide in this matter the sturdy self-sown seedlings of Larkspurs, Poppies, *Eschscholtzias* and *Nigellas*. Most of these ripen seeds in August, and they come up and thrive freely, becoming sometimes almost as bad as weeds. Rigorous thinning is another important matter. It is no use expecting three or four plants to thrive in a space sufficient only for one plant. Thinning, however, should be done by degrees. At least double the number of plants which are to remain to flower should be left for the winter in case of losses, for there are slugs and snails to consider as well as the weather conditions. The final thinning need not be done till March or early April.

Antirrhinums and Stocks are hardy, but in many districts the protection of a cold frame is worth considering. Some of the Sweet Peas, the new and scarce sorts in particular, should be sown in pots and kept in a frame during the winter. *Statice Suworowii* is another plant deserving similar consideration. In bleak and cold gardens, also those situated in confined areas, where sparrows, slugs and snails are pests and try the grower's patience, the garden frame will be found most useful in winter to accommodate *Clarkias*, *Godetias*, *Candytufts*, *Sweet Sultans*, *Star Chrysanthemums*, *Scabious*, *Sweet Alyssum* and *Cornflowers*. Shallow trays or boxes are preferable to pots. Boxes 15 inches by 9 inches, and 2 inches deep, will hold three to four dozen plants, which are sufficient to make several nice clumps in the mixed border or to fill a small bed. An occasional sprinkling of soot and lime all round the sides of the frame, just inside, will stop slugs and snails, and a handy-man will soon make a framework of thin-meshed wire to fit on the top of the frame, as the glass lights should only be used during unfavourable weather.

To Sow Outdoors.—The following annuals do not transplant readily, and should be sown where they are to flower: Poppies, the best sorts being the Shirley Poppy; the double Opium Poppy, 3 feet in height, with greyish green foliage and immense double flowers; the single scarlet and black Poppy, *Papaver commutatum* or *P. umbrosum*, 2 feet to 2½ feet high; and the dainty Iceland Poppies in yellow, orange and white. The tall, branching Larkspurs, 3 feet in height, may be had in mixture or separate colours, Sutton's Rosy Scarlet being one of the best for massing. The Dwarf Rocket Larkspurs are a foot in height, with dense, closely-packed spikes of flowers. Wonderful development during recent years has been noticeable in the *Eschscholtzias*, for, in addition to the old yellow and orange sort, there are several varieties with pretty pink and rosy red flowers. The Cornflower blue

flowers of *Nigella Miss Jekyll* find many admirers, set as they are in a dainty network of narrow foliage, aptly described as Love-in-a-mist. The height of the plants varies from 12 inches to 15 inches.

The next group we may consider are those which may be transplanted, but are preferably sown where they are to flower. Most of these are suitable for small groups or lines along the front of the mixed border, as they range from 6 inches to 12 inches in height: *Asperula azurea setosa*, *Linum Douglasii*, *Collinsia bicolor*, *Phacelia campanularia*, *Saponaria calabrica*, *Virginian Stock*, *Venus' Looking-glass*, *Gilia tricolor* and *Gypsophila elegans*.

Clarkias and Godetias, *Candytufts*, the pot Marigold, *Calendula officinalis*, the blue Cornflower, *Scabious*, *Sweet Sultans*, *Coreopsis tinctoria* and annual *Chrysanthemums* are all of easy cultivation, and may be sown where they are to flower, or on a spare border and transplanted. So much has been said and written about Sweet Peas that most readers will be familiar with their cultivation. Experts are now pretty well unanimous that for garden decoration and show purposes autumn sowing is the best, spring sowing being only necessary to provide a succession of blooms for garden decoration and cutting in August and September.

A useful dozen annuals for cutting are Sweet Peas, *Star Chrysanthemums*, *Orange King Calendula* (also a beautiful plant for massing in the garden), *Coreopsis tinctoria*, German *Scabious*, *Shirley and Iceland Poppies*, arranged with *Gypsophila elegans*, double *Godetia*, *Clarkia Firefly*, blue *Cornflower* and *Spiral Candytuft*.

GERANIUM STRIATUM.

Now and again we come upon this old-fashioned flower, which was known to, and was described by, Parkinson more than 250 years ago, but which has not retained the hold upon the affections of gardeners that it should have done. Probably the bedding mania drove this good hardy plant from many gardens, and it has been well-nigh forgotten by the compilers of catalogues and writers on hardy flowers. Yet it has lingered in many old gardens, and in one of these—a true old-world one—the writer saw, not so very long ago, a big mass of this striped Crane's-bill, with its charming flowers with a groundwork of white, and all veined with a lovely red veining, so delicate and so pretty in its markings that it is almost impossible to credit that it is not artificial, did we not know that Dame Nature in her coloured tracery far excels the handiwork of the most skilful among us. This mass was very pretty, but it did not require it to bring home to the writer the true charms of *Geranium striatum*, for he has known and grown it for a good many years. It is a favourite which he always likes to bring before the notice of the garden visitor who may not have been acquainted with the flower and its delicate pencilling, which gives so much charm to the petals. This Crane's-bill is an easy plant to grow, doing well in either sun or shade, but growing more vigorously in the shade than in the sun, though not, I think, so pretty as in the former. There can be no question as to the hardness of this plant, although it comes to us from Southern Europe, where it has a warmer climate than ours. It adapts itself to the border or to the rockery, and in either gives us high and lasting pleasure indeed.

Dumries.

S. ARNOTT.

TREES AND SHRUBS.

A DOUBLE-FLOWERED CEANOTHUS.

(*C. ALBUS PLENUS*.)

There are only comparatively few shrubs which flower during late summer and autumn. Among

CEANOTHUS ALBUS PLENUS.

these the garden varieties of *Ceanothus* are exceedingly pretty. Most of the spring-flowering section are what may be termed on the borderland of hardiness, and thrive best when planted against a wall, except in mild districts. The autumn-flowering hybrids, on the other hand, seldom suffer when growing in the open, except in the very coldest districts. Compared with the spring-flowering kinds they are even more showy, embrace a wider range of colours, and the blossoms last longer in good condition on the plants. Flowering on the current year's shoots, fairly hard pruning should be practised in February or March to induce the production of vigorous shoots. The plants, as a rule, are grown as bushes in borders or beds, but may also be trained against a low wall or fence. In the latter case a few shoots must be left nearly full length, so that in a year or two the space allotted is covered.

Ceanothuses thrive in most well-drained garden soils, but a heavy clay loam should be avoided. Cuttings root freely during July and August in a close, slightly-heated propagating-frame. Potted off singly when rooted in autumn and kept in a heated pit during the winter, good bushy plants can be obtained full of flowers the following autumn. To lay a good foundation, remove the tips of the young shoots once or twice when the plants are small. One of the secrets of success with the garden varieties of *Ceanothus*, which are hard pruned each

spring, is to raise a fresh supply of young plants from cuttings about every fourth or fifth year.

Shrubs with blue flowers are not numerous; with the *Ceanothuses* it is the predominating colour. The following list comprises a representative selection: *Albert Pittet*, light pink; *albus plenus* (illustrated), double white, changing to cream; *Cerès*, dwarf, light pink; *Charles Détriché*, deep blue; *Coquetterie*, rose carmine; *Croix du Sud*, dark blue; *George Simon*, carmine pink; *Gloire de Plantières*, deep azure blue; *Gloire de Versailles*, light blue; *Indigo*, indigo blue; *Marie Simon*, pink; *Perle Rose*, rich deep rose; *Pinguet Guindon*, deep carmine; *Sirius*, metallic blue; and *Arnoldii*, greyish blue.

SPIRÆA WILSONII.

This *Spiræa*, introduced a few years ago from China by Mr. E. H. Wilson when collecting on behalf of Messrs. James Veitch and Sons, is proving to be a useful addition to our deciduous flowering shrubs. Robust in growth, *Spiræa Wilsonii* forms a large, spreading bush, 5 feet to 6 feet or more in height. The inflorescences of white flowers terminate short axillary shoots, which develop from the upper two-thirds of last year's vigorous shoots. As these bend over in a graceful, arching manner, a bush in full flower presents a pleasing picture. The flowers are borne in flattened, rather compact, rounded corymbs about the middle of June. The corymbs are $1\frac{1}{2}$ inches to $2\frac{1}{2}$ inches across, the individual flowers a quarter of an inch in diameter. In addition to *S. Wilsonii*, Mr. E. H. Wilson has introduced three other closely-allied species, namely, *S. Henryi*, *S. Veitchii* and *S. sargentiana*. These four *Spiræas* are very appropriately named in compliment to four persons who have spared no efforts to enrich our gardens with plants from Central and Western China. *S. Wilsonii* differs from *S. Henryi* in its smaller, more compact inflorescences and the slightly shorter and rather narrower leaves, and the flowers open from two to three weeks earlier than that species. These *Spiræas* thrive in any good garden soil, and are readily propagated from seeds or cuttings. The latter, made of the half-ripened shoots, root freely during August or September in pots of sandy soil in a close propagating-frame. The long, arching branches also layer readily. Forming a shapely bush, *S. Wilsonii* makes a nice lawn specimen for small or large gardens, while for large clumps and shrubby borders it is well worth consideration. An occasional thinning out of the older branches immediately after flowering is desirable, to give the young shoots space to develop and ripen their growth.

CHOICE BERRY-BEARING TREES AND SHRUBS.

There are not wanting signs of an early autumn, so that notes on berry-bearing trees and shrubs may not be out of place at this season.

Everyone is aware of the beauty of the *Pyracantha* or Fire Thorn, for it makes many a wall gay for several months of the year. Then there is its near relative *Cotoneaster angustifolia*, or *Pyracantha angustifolia* as people are now beginning to call it. This also is an evergreen, but the fruits are orange or golden in colour. Less hardy than the ordinary *Pyracantha*, it should always be placed against a wall, except in the South or South-West Counties. Light, loamy soil suits both plants. The different kinds of *Cratægus* or Thorn are, as a rule, very showy when in fruit;

but if a few kinds only are wanted, preference should be given to *C. mollis* and *C. coccinea*, with large, bright red fruits; *C. punctata*, with dark red, and its variety *xanthocarpa*, with yellow, fruits; *C. cordata*, with small, orange scarlet berries; *C. prunifolia*, with red fruits; and *C. Carrièrei*, with orange and red haws. These are all perfectly hardy, and all thrive in ordinary garden soil. They do not require any special pruning, an occasional thinning being all that is necessary.

Many of the *Cotoneasters* take high rank among berry-bearing plants. For many years we have had a number of showy kinds from the Himalaya, while recent years have witnessed the introduction of other beautiful sorts from China. Even at the end of February their season of beauty is not over, for we may see masses of *C. rotundifolia* covered with bright red berries, a condition which has prevailed since the early days of September. For some reason this species is not troubled by birds in the way that others are, and the birds only take the berries when nothing else can be obtained. This particular species grows about four feet high, and forms a good-sized bush of open habit. *C. horizontalis* is another useful plant which thrives well on a dry bank or against a wall. Its berries are scarlet. *C. thymifolia* and *C. microphylla* are two evergreen kinds of dwarf habit suitable for growing on banks or rockeries. The berries are

SPIRÆA WILSONII.

red. Although naturally dwarf-growing kinds, they are excellent for walls, and readily attain a height of 15 feet in such a position. *C. pumosa* and *C. Franchetii* are Chinese species which grow 8 feet or 10 feet high, with a free branching habit. The scarlet berries are freely produced, but their effect is somewhat marred by the light covering of greyish down with which they are protected. Two quite new species of exceptional merit are *C. bullata* and *C. applanata*. Both are Chinese species of bushy habit, bearing bright red fruit. In the case of the former they appear in rather large bunches. *C. acutifolia*, although not a new plant, has been brought into prominent notice by a particularly tree-fruiting form which has appeared from China. Everyone should obtain it who is fond of red-berried shrubs. The old *C. Simonsii* has been a friend for many years. Of upright habit, it bears yellow and red berries with great freedom. *C. frigidula* is perhaps the giant of the group, and may sometimes be met with between 20 feet and 30 feet high. Its large heads of bright red fruits are particularly showy in autumn.

Pernettya mucronata is a dwarf, evergreen, berry-bearing shrub belonging to the Heath family. Growing about one and a-half feet to two feet high, it is conspicuous throughout autumn by reason of its red berries. There are varieties with light and dark red fruits, and others with white and purple fruits. Rather moist soil should be provided, and notice must be taken of its dislike for lime. Another decorative fruiting plant belonging to the Erica group is the Strawberry Tree (*Arbutus Unedo*). This forms a large bush or small tree with evergreen leaves, rather showy flowers and round, orange and red fruits, which are covered with short, spiny excrescences.

The Pyrus family contains a great many ornamental kinds. The Siberian Crab and its varieties, together with its close ally *P. prunifolia*, produce particularly bright-coloured fruits, while the various forms of *P. Malus*, of which John Downie, Dartmouth and Transcendent Crab are worthy examples, are all useful. The Rowan (*P. Aucuparia*), and its varieties, together with the American Rowan (*P. americana*), are general favourites; but, unfortunately, the berries are often taken by birds as soon as they are ripe. *Pyrus Aria* (the White Beam Tree) is showy in hedgerows in some parts of the country. Its several varieties, however, are well worth a place in the garden. When one only is required, the variety *majestica* should be chosen. A closely-allied tree is *P. rotundifolia*. Like the *Aria* varieties, it bears good-sized heads of red fruits. *P. intermedia* and *P. pinnatifida* belong to the same set. They also are showy, and possess the advantage of being excellent trees for planting in town gardens.

The new *Berberis Wilsonæ* is one of the most beautiful fruiting kinds among the newer *Berberis*; its fruits are red. In the same family there are many kinds of decorative value, notably *B. dictyophylla*, *B. Lycium*, *B. arstata* and the common *B. vulgaris*. For fragrance, nothing is more prominent than the dwarf-growing *Cydonia Maulei*. The golden fruits are an inch or more in diameter, and scent the air for a considerable

area in the vicinity of a bush. *Rosa rugosa* is perhaps the most showy Rose when in fruit, but all the kinds are worthy of attention, particularly *R. alpina pyrenaica*, *R. macrophylla*, *R. canina* and *R. lucida*. *Euonymuses* are represented by many showy species, notable ones being *E. europæa*, *E. latifolia*, *E. americana* and *E. planipes*.

The list might be added to considerably, but those mentioned serve to direct attention to the best for general purposes.

W. D.

ROCK AND WATER GARDEN.

THE CAMPANULAS OR BELL-FLOWERS.

IT is difficult to conceive a more valuable class of plants for the outdoor garden than the Campanulas or Bellflowers. They are most diverse in their habits of growth and in their general appearance. They present

in the border. For example, *C. carpatica* and its forms, with *C. portenschlagiana* and a number of others, make excellent border flowers in a moderately light soil. So, also, the owner of a large rock garden may utilise some of the taller species mentioned for borders for the decoration of his rockeries. Some of these are, indeed, of remarkably telling effect in certain parts of the rock garden, where their impressive appearance is fully appreciated.

Campanulas for the Rock Garden.—The wealth of these lovely flowers is embarrassing in the extreme, but one can hardly have too many, especially as they are so valuable after early alpins are out of flower, and are so distinct from the other plants which bloom from June onwards. A considerable number are remarkably easy to cultivate, and call for little attention for years, except division, when they grow too large, and some top-dressing in autumn and spring. Others require more care, and these will be referred to

THE WALL HAREBELL (*CAMPANULA PORTENSCHLAGIANA*) IN THE ROCK GARDEN.

us with species suitable for the choicest rock garden or flower border; they supply us with plants for bedding or for the mixed border; while in the wild garden a number of the stronger growers can be accommodated with advantage. As they differ in appearance, so do they vary in their cultural requirements. Some are extremely easy to cultivate in ordinary soil, while others call for the best skill and care of the cultivator in giving them what they desire in the way of aspect, soil, or moisture.

In discussing the Campanulas it is difficult to arrange them in groups, but the writer thinks it advisable to divide the perennial and biennial species and their varieties into two sections, not according entirely to their heights, but because the first group is, as a whole, better suited for the rock garden than for the border. Any of the best alpine Campanulas will, however, succeed

under their names. Generally speaking, they can be raised from seeds, or increased by division in spring or autumn. Seeds may be sown from February to June under glass, or as soon as they are ripe, in pots or pans of sandy soil slightly covered with fine earth and placed under glass. Seedlings should have air as soon as they show above the ground, ought to be pricked out as soon as they are fit to handle, and be planted in their permanent positions after growing on. Some root from cuttings, but division is the best method to adopt with many. If small pieces are taken, they should be potted and nursed under glass for a short time before committing them to the rockery. The writer finds that partial shade is excellent for most of the dwarf Campanulas, and that they last longer in bloom there than in full sun. On the other hand, some require full sun. A sandy, gritty soil is best for most of these

rock garden Bellflowers, but certain species either require or are best grown in the moraine, in which most of them will thrive admirably. The annual species will be mentioned briefly at the close of these articles. Synonyms abound among the Campanulas, and there are grave differences among those best acquainted with them as to their true names. No claim is made to infallibility on this point, but the best authorities are followed, unless for reasons which appear to the writer to be conclusive.

Campanula abietina.—A well-known rock or border plant, growing about nine inches high, but occasionally exceeding this, and bearing upright, open flowers of purple. It does well in gritty soil, but should be divided every two years, or it will flower sparsely and may die out. It requires a good deal of moisture during the growing season. A South European species, liking sun, and flowering in June and July.

C. Adami.—See *bellidifolia*.

C. Allioni.—One of the troublesome but most beautiful of the rock garden Campanulas. It has rather hairy leaves and big blue bells in July, and is only 2 inches or 3 inches high. Grow in very sandy, gritty soil and in semi-shade. It needs top-dressing in spring and autumn, and soakings with water in spring and summer. The moraine is the best place for it. As with many others, slugs should be guarded against. There is a beautiful white variety. Lime should be kept from this plant. S. ARNOTT.

(To be continued.)

A BEAUTIFUL GERANIUM.

GERANIUM LANCASTRIENSE originating, I believe, in the Isle of Walney, is a variety of *G. sanguineum*, and not only has it at one leap altered its colour from magenta crimson to a delicate pink, veined with fine purplish red lines, but the bushy, sprawling hummock of its progenitor has given place to a close-growing, compact habit, which makes it an ideal plant for the smallest rock garden. My plants, which are growing in an open, sunny spot, in gritty, though otherwise ordinary soil, do not exceed 2 inches or 3 inches in height, while the whole carpet, composed of deeply-divided leaves, is, during June and early July, one mass of blossom, which latter, owing to the deeply-coloured veins, has the appearance of a much richer colour than the groundwork of the petals themselves. The buds nod very gracefully, while after pollination the long, spear-like fruits are held quite erect. The texture of the petals suggests crumpled silk, while the stigma and filaments, with their rich pink coloration, are in striking contrast to the anthers, which are yellowish buff. This year in particular the plants have set a considerable quantity of seed, and I am hoping to raise a number of further plants therefrom. It is interesting to notice on a dry day, when the fruits are ripe, how the carpels split, each

portion curving into a kind of spring, which enables the seed to be thrown to a considerable distance.

REGINALD A. MALBY.

LINUM ARBOREUM.

THIS is, to my mind, the best of the yellow forms of Flax. It flowers so wonderfully freely, and is of such a delightful clear Daffodil yellow, lighter and with less of orange in it than in *Linum flavum* or *L. capitatum*; and also, when out of flower, the leaves are attractive by reason of their colour, a good glaucous green, almost steely blue. Here it is not a very long-lived plant, three year old plants often perishing in winter or appearing to flower themselves to death; but as it is easily struck by cuttings it should be treated as one

GERANIUM LANCASTRIENSE, FLOWERS DELICATE PINK.

would a Cistus and keep a reserve of young plants to fill up gaps. The illustration on page 435 is of a plant moved to its present position last autumn and about two years old. The effect of its brilliant yellow flowers against the grey Kentish Rag rock was very delightful. It comes from the Levant, and is one of the many good things introduced by Sibthorp, the author of that magnificent book, the "Flora Græca." In his day it was grown as a greenhouse plant, and is said to form bushes several feet high under that treatment. Here in the open I have never known it get much higher than a foot before it was killed. Young plants are certainly hardier than older and more woody specimens, as is the case with so many of the more tender Cistuses.

Waltham Cross.

E. A. BOWLES

HERBACEOUS BORDERS AT SALISBURY CLOSE.

(See Special Supplement.)

THE herbaceous borders of the North Canonry Garden in the Close at Salisbury are beautiful not only in themselves, but also in regard to their surroundings. They face north and south, and the soft green turf walk that divides them is 115 yards long. Westwards, one looks on to the Avon and its green water-meadows beyond; eastwards, on the old canonical house and the great cathedral spire towering behind and above it. The borders are 12 feet wide and always full of colour, from the early spring, when the Crown

Imperials are a special feature, through the summer months on into the autumn. But perhaps their time of perfection is the latter half of June or the month of July. Then, one cannot easily forget the beauty of the climbing Roses (Crimson Rambler, Hiawatha, Lady Gay, Captain Christy, Dorothy Perkins, Olga de Wurtemberg and many others) at the back of the border, of masses of Delphinium, Anchusa, Spiræa, Cimicifuga, Pyrethrum and Campanula; and in the foreground bush Roses and Violas of every kind and description. Their season, however, is well-nigh over, in this month of August, but their places are filled by more autumnal blossoms. Phlox and Helianthus, Erigeron and Echinops, Tritoma and Antirrhinums of various species, and clumps of Gypsophila and Statice are giving a wealth of colour and beauty to the borders now that makes one cease to regret their forefathers.

CONSTANCE PAGE-ROBERTS.

SWEET PEA MOTHER O' PEARL.

IN a very odd way Mother o' Pearl has had the interesting experience of waking up to suddenly find itself famous. I am surprised at the number of enquiries I have had about it, and all because I said it was sweet. It is clear that scent is still appreciated, although it seems to have been so much neglected in the evolution of the much-belauded beauties of to-day that one might

well think it were otherwise. Mother o' Pearl was raised by Mr. H. Aldersey of Aldersey Hall, Chester, and was the result of a cross made in 1900 between Mrs. Fitzgerald and Lady Grisel Hamilton. It was one of the F² seedlings which survived the wet summer of 1902, and it was fixed by the old-fashioned pre-Mendelian system of the gradual elimination of the rogues. I once asked Mrs. Aldersey which was her favourite Sweet Pea among all that her husband had raised. Her answer was unexpected: "Mother o' Pearl, because of its delicate colour and sweet scent." Mr. Aldersey tells me that his Moonstone and Opal are the result of a Countess Spencer selection crossed with Mother o' Pearl. In both the delicious fragrance of the pollen parent has to a very large extent been retained. JOSEPH JACOB.

DAFFODIL NOTES.

Midland Daffodil Society's Affairs.—In the first week in August, Mr. Herbert Smith (the hon. secretary), Mr. C. L. Adams and myself had an informal meeting to talk over the affairs of the Midland Daffodil Society. Mr. Smith said that he would be able to continue to act as secretary as heretofore, and that the society might count on the same clerical help from the staff of Robert Sydenham, Limited, as has been so unsparingly given in the past. This is good news indeed, for next to the personality of our late treasurer I look upon these as the two most important factors in the building up of our annual show. They are the sure foundations on which the superstructure of bloom is laid. Another point that was discussed was the annual dinner.

It was, of course, the private affair of Mr. Sydenham, but it was invariably given and conducted in such a way that it seemed to have become part and parcel of the show. Several expressions of opinion had reached us as to the advisability of trying to continue it. It was eventually settled that Mr. Adams should sound certain members to see if enough support could be obtained, apart altogether from the funds of the society, to make the holding of an annual dinner a possibility. The result is to be reported to a general meeting, which it is proposed to hold in the early part of December. Until then, too, Mr. Smith will act as hon. treasurer.

The Midland Daffodil Society's Report and 1914 Schedule.

—There is but little to comment upon in either. In the latter it will be noticed that the seedling and new varieties section has been still further extended by the inclusion of two new classes, one for three distinct varieties not in commerce, of which nine stems of each must be shown, and the other for six distinct varieties of white trumpet Daffodils that have not been in commerce more than four years, in which whiteness is to be the supreme test. I feel sure this policy of extension is sound and wise. Seedling-raising has spread, and continues to spread, among Daffodil-lovers, and every society ought to provide as many opportunities as possible for its members to display their achievements in friendly rivalry.

Royal Horticultural Society's Classified List of Daffodils.—I am glad to say that a new edition of this necessary little book for show men will be issued this autumn. I wonder how many hundred names will be in it! Will it be possible to keep it up to date now so many seedlings are coming up? The task is one of increasing difficulty, and yet its necessity does not diminish, as Colonial and Dutch seedlings must be now reckoned with. No one wants Admiration to be one variety in Holland, another in New Zealand, and a third at home.

A New Zealand Narcissus Committee.—I fear I am very ignorant about the domes of Australasian Daffodillers. I knew that there were fine shows down in those distant parts of our Empire, and that the names of Alistair Clarke and Thomas were household words as seedling-raisers; but I had no idea until recently that events had so far progressed that a Narcissus committee was in existence in the Canterbury Horticultural Society, whose headquarters are at Christchurch. A most interesting paper will appear in the Bulb Number of *THE GARDEN*, written by the secretary of this committee, dealing with the progress of the flower in New Zealand.

The Royal Horticultural Society's Daffodil Year Book.—Before these notes are in print the publication of the Year Book will be an accomplished

THE FRUIT GARDEN.**TREATMENT OF RASPBERRIES AFTER FRUITING.**

IT is a matter of much importance, especially if the crop has been a heavy one, to cut out all the old fruiting canes immediately they have ceased bearing, and also the young, useless growths not required for next season's crop. Raspberries are among the easiest of fruits to cultivate, and if given reasonable attention produce a very profitable return. They delight in a rather moist, well-drained, fertile soil, and, being essentially surface-rooting plants, require all the fibrous roots to be preserved as much as possible and liberally fed with liquid manure in hot, dry weather, together with good mulchings of thoroughly-decayed manure.

LINUM ARBOREUM IN MR. E. A. BOWLES' ROCK GARDEN. (See page 434.)

tact. I would like to take this opportunity of saying that I hope readers will remember that it is a "first attempt," and, secondly, that I was not appointed to collect material until it was too late to make full arrangements about getting reports of provincial shows. These, I trust, will be fuller and more plentiful another year, should there be sufficient support forthcoming to warrant a second attempt. Naturally, the Royal Horticultural Society has a mercantile side; or, to put it plainly, a second Year Book depends upon the number of copies of No. 1 that are sold. The price is 1s. 6d. (or 1s. 9d. post free), and it may be had from the Royal Horticultural Society's Offices, Vincent Square, Westminster. *Verb. sap.*

JOSEPH JACOB.

Our favourite variety here is Superlative, and if the berries are not as sweet as some, they are most abundantly produced in the majority of seasons. The soil at Wrotham Park is rather light, resting on gravel, so that constant attention to liberal feeding is of the greatest importance to maintain healthy, fruitful canes.

About the end of July or the beginning of August all the old canes are cut down to the ground, taken away and burned, and the strongest of the young growths which have been made this season are tied rather loosely to the wires about six inches apart, so that both light and air may circulate freely among them to encourage firm, well-matured canes. If it is intended to make fresh plantations when the proper time for planting arrives, some

of the small canes may be removed carefully with roots attached and planted temporarily for the time being. Having gone carefully over the beds and put them in order, we usually apply a good coating of manure on both sides of the rows, and give a thorough soaking of water if the weather proves very dry.

H. MARKHAM.

Wrotham Park Gardens, Barnet.

HINTS ON RIPENING MELONS.

In hundreds of gardens Melons will be ripening during August and September, and inexperienced cultivators will hesitate as to whether they should water as usual or withhold it. During a rather long experience as a Melon-grower I do not remember having had a single failure owing to watering generally. I have seen many plants killed prematurely through lack of moisture at the roots after the fruits began to colour and mature. Of course, the plants do not need as much moisture at the roots nor in the air at the stage referred to, but I never

THE GREENHOUSE.

ERLANGEA TOMENTOSA.

THIS pretty Composite, which is closely allied to *Vernonia*, is so useful for conservatory decoration that it is worthy of more general cultivation. It was introduced in 1907, and is a widely-distributed species in Tropical Africa, ranging from British East Africa to the Zambesi. Its pretty pale mauve flowers are very attractive, having a resemblance to a *Eupatorium*. It is easily propagated from cuttings placed in a warm case. From cuttings rooted early in March large plants some 5 feet high can easily be grown in one season, stopping them several times to ensure a bushy habit. Such plants require to be potted on until they are in 8-inch pots. They commence flowering early in the New Year, and continue in good condition until June.

out of doors, it is greatly appreciated for the embellishment of the garden in many ways. Grown in large pots or tubs it forms a notable feature on terraces, balconies or similar positions, and either as bushy specimens or as comparatively small plants it is much grown for the decoration of the greenhouse or conservatory. The cause of the *Hydrangea* changing its normal pink flowers to some shade of blue has aroused a considerable amount of interest. It is usually considered to be due to the presence of iron in the soil; but absence of lime would also appear to play a part.

Probably in no other way does the *Hydrangea* appeal so much to the general public as when grown in comparatively small pots and confined to a single stem, each plant carrying one huge head of blossoms. For flowering next year in this fashion the cuttings should be taken at once, selecting for the purpose shoots that, if left on the plant, would, as far as can be determined, flower next year. Put in sandy soil and placed in a frame kept close and shaded, they will soon root, and must then be wintered in a cool greenhouse or in a frame safe from frost. The cuttings should be put into single pots, so that they may, if required, stand the winter without being disturbed. Some, however, for the sake of succession, prefer to shift some of the strongest plants into larger pots as soon as they are sufficiently rooted.

The common *Hydrangea*, the dark-stemmed variety *cyanoclada*, and *Thomas Hogg*, with smallish heads of white flowers, were for many years the principal kinds grown. Then came *Mariesii*, with very large sterile blossoms, but limited only to a few around the outside of the cluster. The colour of this is pink, but there is a white form known as *Veitchii*. Within the last few years, however, a great number of new garden varieties of *H. Hortensia* have been raised, chiefly on the Continent. Many of them are very fine, and one at least may be said to have bounded into popularity, namely, *Mme. E. Moullière*, which bears enormous heads of white flowers. This quickly became an established market plant. Another new kind is *Lilie Moullière*, whose flowers are of a bright rose pink with a light centre. *La Perle* is another beautiful pure white flower, remarkable for its fringed edges. E. G. Hill, said by the raiser—M. Lemoine—to be the result of a cross between *H. rosea* and *H. Otaksa*, is a very fine variety with soft rose flowers. The largest individual blossoms, but they are not very numerous, are those of *Beauté Vendômoise*, of a pale mauve tint. A variety which Messrs. Cutbush of Highgate, who grow these plants so well, say, if treated with their preparation, makes the finest blue *Hydrangea* bears the extremely long name of *Générale Vicomtesse de Vibraye*. Another of the newer kinds that has caught on in this country is *Mlle. Renée Gaillard*. This bears huge heads of milk white flowers, whose edges are markedly toothed.

While all the above are forms of *H. Hortensia*, another totally different species is largely employed for greenhouse decoration. This is *Hydrangea paniculata grandiflora*, which, if pruned back hard and well fed, produces huge heads of creamy white blossoms. Out of doors it does not, as a rule, bloom much before August, but brought on under glass it may be had in flower a good deal earlier. A variety of the North American *H. arborescens* known as *grandiflora*, with rounded heads of pure white flowers, something like those of the *Snowball Tree*, was sent here from America a few years ago, and increases in popularity each season. H. P.

ERLANGEA TOMENTOSA, WITH ATTRACTIVE PALE MAUVE FLOWERS.

favoured the drying-off system. The withholding of water is generally adopted with the idea that the fruits will be richer in flavour. If carried too far, the system will result in loss of flavour instead of an increase. It is a fact that thousands of plants are practically dead when the fruits are gathered, whereas they ought to be in a condition to bear a second crop on extended laterals if necessary. I always continued the supply of water up to the time the fruits were ripe. At first, when the Melons gave off a slight aroma, less water was applied. During the last week sufficient water was given to keep the leaves plump and in a fresh condition only. The Melons were cut directly they were ripe enough and stored in a cool room for two days before they were cut open, and very few approved varieties failed to give satisfaction. Plenty of air was admitted during the ripening period, and on hot days the floor was freely damped. B.

From later-rooted stock nice useful plants in 4½-inch pots can be grown, as shown in the illustration. In its earlier stages it may be grown in an intermediate temperature; afterwards ordinary greenhouse temperature is all that is necessary. There are two forms in cultivation, one the typical plant with grey, tomentose leaves. The other form has smaller green leaves, and is not such a coarse-growing plant. On this account it is better suited for growing in small pots, as it has a stiffer habit, and its flowers, if anything, are darker in colour. J. S.

HYDRANGEAS IN THE GREENHOUSE.

In the more favoured parts of these islands the common *Hydrangea* (*H. Hortensia*) is justly valued as one of the finest outdoor shrubs. Even where it cannot be depended upon to prove satisfactory

GARDENING FOR BEGINNERS.

HOW TO INCREASE VIOLAS.

THERE are few gardens, both large and small that can afford to dispense with the bedding Violas or Tufted Pansies. They are so easy to grow, thriving in most soils and situations, and with care and attention will continue in flower for six or seven months, namely, from April to October. And when in bloom

and sand. Press the soil fairly firm, and spread over it a thin layer of fine sand to trickle in round the cutting as each hole is made with a dibbler and the cutting inserted. As soon as each hand-light or box is completed, water the cuttings well with a fine rose on the watering-can. A box of the size given will hold fifty cuttings. Rather more space may be allowed when dibbling them in a frame on a prepared border, 1½ inches apart and 2 inches between the rows being a convenient distance.

A selection of good free-flowering sorts for beds and borders is as follows: White Swan, Primrose Dame, Canary, Moseley Perfection (large rich yellow), Maggie Mott (mauve), Councillor Waters (magenta purple), Bridal Morn (heliotrope blue), Archie Grant (midigo blue), J. B. Riding (rose purple), Kitty Bell (lilac), Kingcup (rich yellow), Mrs. H. Pearce (pure white) and Peace (white, edged heliotrope).

Those readers who would like to make a hobby of choice exhibition Violas, either for show or for the pleasure of their family, will find their culture full of interest. Quality of the flowers rather than quantity in this case is, of course, the primary consideration. Those who have used Violas for dinner-table decoration are loud in their praises of them. Many people think them too common, but it is not always the most expensive flowers which produce the best effects. Try, to start with, a table of Maggie Mott, lightened with a few pieces of the perennial *Gypsophila paniculata*. With the choice exhibition sorts use pots for the cuttings, as the numbers inserted will be much less. When nicely rooted, plant them out 3 inches apart on a prepared bed in a cold frame for the winter. Give plenty of ventilation during the winter, only closing the lights entirely on frosty nights and removing them altogether on warm, sunny days. April is a good time to plant them out where they are to flower.

Twelve choice exhibition sorts are George C. Murray, Goalkeeper, Jessie Baker, Jeanie Stirling, Jenny Houston, Kate Cochrane, Lady Knox, Mrs. Chichester, Mary Burnie, Mrs. H. Pearce, William Lockwood and Rose Noble. With the choicer sorts, at this season some difficulty may be experienced in obtaining cuttings. To encourage their production give the plants at once a liberal top-dressing of rich soil, using, mixed with it, Clay's Fertilizer or guano. We have used flaky leaf-mould and Clay's Fertilizer, with very good results. Following several good soakings with water the increased vigour of the plants will soon be noticeable. Other measures to take to induce the production of cuttings is to cut off some of the oldest growths and keep all seed-pods picked off.

Raising from Seeds.—There is even more interest attached to the raising of Violas from seeds than there is in rooting cuttings, for on the one hand the colour of the flowers is already known, but with seedlings their flowering is awaited with interest. Recently, when on a visit to Messrs. Sutton's Trial Grounds at Reading, a large stretch of mixed seedling bedding Violas was noted being grown for seed, a considerable number of the flowers being equal to many named sorts. Seeds sown thinly now in a shallow box and placed in a cold frame will give good plants for next season's flowering. In addition to a packet of mixed seeds,

those who wish it can purchase seeds in separate colours, these including white, yellow, primrose, black, purple and mauve. A. O.

MIGNONETTE FOR WINTER FLOWERING.

A FEW pots of well-grown Mignonette make a charming feature in the greenhouse or conservatory during the latter part of winter and in spring. If carefully grown, splendid specimens will result. I remember assisting in making the awards at a spring flower show, and, among other kinds of plants, there were pots of Mignonette. The size of the pots was restricted to 6½ inches. In some pots only one plant was grown, in others two and three plants respectively. All were very fine, but the pot with the single plant was the best. The plant had branched out wonderfully, and appeared of greater bulk than the three plants in a pot; furthermore, the flower-spikes were larger.

Sowing the Seeds.—It is not advisable to sow seeds too early, else the resultant plants will flower prematurely, however much the cultivator strives to prevent this, and they should be kept growing steadily. Drop three seeds in a 3-inch flower-pot filled with loam and leaf-soil in equal proportions. To one bushel of the combined parts add a 7-inch pottful of rotted manure and a 6-inch pottful of coarse sand. It procurable, add a small quantity of road scrapings. Lightly cover the seeds and then place the pots in a cold frame, but admit plenty of air, as it is necessary to prevent the resultant seedlings becoming drawn and weakly. In fine weather, as the seedlings gain strength, remove the glass lights altogether; also draw out the two weakest plants, leaving only one plant in each pot. Before the plant gets pot-bound, repot in a 5-inch pot, using a similar compost. When the plants are about four inches high, pinch off the tops, and thus cause side shoots to grow. Sometimes five or six strong shoots may be secured, and these will be sufficient to form a nice specimen. In due course one more repotting may take place. From October to the flowering stage place the plants on a shelf in a greenhouse, and always water carefully. B.

1.—THE GROWTH ON THE LEFT, BEING COARSE AND HOLLOW STEMMED, IS OF NO VALUE AS A CUTTING. ON THE RIGHT IS SHOWN THE BEST FORM OF CUTTING, BEING OF RECENT DEVELOPMENT AND ABOUT 2 INCHES IN LENGTH.

what a blaze of colour they make! and there is such a wide range of colours to choose from. August and early September are the best months to insert cuttings. There are on most of the plants at this time plenty of young shoots, 1 inch to 2 inches long, pushing up in the centres of the tufts of growths. Try to pull these out carefully, not cut them with a knife, and if a few roots are already attached so much the better. Inserted now while the nights are warm, the cuttings will soon develop into sturdy young plants, quite able to stand the winter in the open if the protection of a cold frame is not available.

A good position to root the cuttings is under the shelter of a north or west wall, where plenty of light will reach them, but little or no sun. Should it be intended to insert several hundred cuttings, a bed of light sandy soil may be made up on the border and hand-lights or a frame placed on it. For smaller quantities use shallow boxes, a convenient size to handle being 15 inches by 9 inches, and 2 inches deep. A suitable compost or mixture of soil consists of two parts sandy loam, one part flaky leaf-mould, and one part road grit or coarse

2.—THE CUTTING ON THE LEFT IS PREPARED FOR INSERTION. ON THE RIGHT IS SEEN A GROWTH WITH A FEW ROOTS ADHERING, SUCH GROWTHS ARE MOST USEFUL FOR PROPAGATION.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Early - Flowering Chrysanthemums.—The earliest varieties are already making a good show of bloom, and to prolong the flowering period they must be kept fairly moist at the root. Thrip has been somewhat troublesome this season, and wherever this pest is present, the plants should be sprayed with an insecticide, afterwards giving them a good wash over with the syringe or hose. The plants that are being grown for cut flowers will, naturally, be cut over as the blooms open, but those for garden decoration should have the stale blooms removed as often as necessary.

The Herbaceous Border.—There is always a certain amount of work on the herbaceous border, and just now, when many of the summer-flowering plants are going over, there is much to do, cutting down and making tidy so that the dead and dying flowers do not in any way detract from the beauty of those that are opening. At the time of writing, herbaceous plants are suffering severely for want of rain, and should we not get it in quantity during the next week or two, it will mean the weakening, if not the loss, of many of the more tender subjects, unless, of course, they have been systematically watered.

Plants Under Glass.

Mignonette.—The present is a very suitable time for making a sowing of Mignonette for spring blooming. I prefer to sow a few seeds in 3-inch pots, thinning the seedlings to four or five when large enough to handle, and potting on into $4\frac{1}{2}$ -inch pots or 6-inch pots at the turn of the year, or as soon as fit. For the production of large spikes of bloom, firm potting is very essential, and where sowing direct into the flowering pots is practised, the soil should be well rammed; but in this latter case the watering must be carefully done, or the larger body of soil soon becomes sour; hence the advice as to sowing in 3-inch pots.

Schizanthuses.—These may also be sown in the manner advised for Mignonette, thinning to one plant in a pot when large enough; or they may be sown in pans, pricking off before the seedlings become too large.

Clarkias call for similar treatment; but in this case they should be sown in pans or boxes and pricked off. Firefly, Salmon Queen, Brilliant Princess and White Prince are all desirable varieties. To be really successful with these annuals they must be carefully looked after during the dull days of late autumn and winter, careful watering and plenty of light and air being absolutely essential, so that a good, airy house or well-ventilated frame should be devoted to them.

Laehenalias.—A batch of this pretty spring-flowering bulbous plant should be potted up at once into $4\frac{1}{2}$ -inch pots, this being the most useful sized pot for the subject. A fairly rich and open compost suits them well. After potting and watering in, the pots should be stood in a frame where a mat can be put over them to prevent them drying out too much till growth commences. The variety Nelsonnis perhaps the best, while *L. pendula*, tricolor and quadricolor are distinct and pretty.

Begonia Gloire de Lorraine.—If any of the plants are not in pots sufficiently large for their requirements, no time should be lost in getting them potted on, and at this time a large shift should not be necessary. Where good bushy specimens are required, the plants should be staked out as soon as the side growths are sufficiently long to warrant it, and if these are staked out fairly flat they will soon make breaks and so fill up the centre of the plants. Plants well rooted in the flowering pots may be fairly liberally treated as to water and liquid manure.

Begonias Gloire de Seceaux, haageana, &c., that are being grown on for winter and spring decoration, should be potted on as soon as fit into 6-inch pots or $8\frac{1}{2}$ -inch pots, giving them a good rich compost, so that with plenty of room they may develop their rich foliage to the fullest extent. Occasional sprayings overhead are necessary to keep the foliage clean, but, as the days shorten, this may be dropped in favour of frequent sprayings between the pots, or it may be found that the foliage will get rather soft and the edges become

marked. To keep down mite or thrip, a light fumigation should be given now and again.

The Kitchen Garden.

Cauliflower Autumn Giant should now be turning in, and it may be found necessary to keep the plants frequently watered if good heads are required. If pulled up when quite tight, they will keep for some days if stored in a cool shed or cellar and the light kept from them.

Autumn Broccoli also may be subjected to the same treatment. In many places the growth made during the summer has been somewhat irregular; but now that the sun is losing its strength somewhat, one or two good waterings might materially help them.

Onions.—Autumn-sown and spring-planted Onions from boxes are now ripening fast. This being the case, they may be eased from the ground a little, and when it is found that the roots have no further hold of the soil, they should be taken up and placed on hurdles or mats to facilitate the drying process. This latter should be carefully done, as these large Onions, if well ripened and dried, will keep almost as long as the smaller ones.

Spinach.—A good sowing of Spinach should be made during the next few days to stand the winter, and if the soil is heavy, it is a good plan to throw out a narrow trench on each side of a bed about six feet wide, this raising the soil a few inches and at the same time keeping it well drained.

Hardy Fruits.

Plums.—Many varieties are now ripening fast, and every precaution must be taken against wasps and birds. For bottling or preserving purposes the fruits should not be allowed to remain till they are dead ripe, or the skin is likely to be damaged in the gathering. This, the cooks inform us, is not at all desirable, and those of us who are in charge of gardens know full well we have to study the *chef de cuisine*.

Loganberries that have finished fruiting should have all the old wood taken out, tying in only those growths that are required for next season's fruiting. If these are not as strong as one would wish, a good soaking with liquid manure will probably have the desired effect, as the plants make a good deal of growth during the early autumn.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Autumn Propagation.—This work must now be prosecuted with vigour. Calceolarias need not be propagated for another month yet, and there is no hurry for bedding Violas. Among plants which should now be propagated are Ageratum, Alyssums, Petunias, Fuchsias, Phloxes, Pentstemons, Antirrhinums, Anemis Kelwayi, &c. A compost of loam, leaf-mould and sharp sand in equal parts suits the purpose admirably. Shallow boxes provided with openings for drainage will be found the most suitable kind of receptacle for the cuttings. Pass the compost through a half-inch wire sieve and place the rough portion in the bottom of the boxes. Press the soil very firm, and it is an advantage to finish off with a little clean sand. Insert the cuttings somewhat thickly, but according to the vigour of the subjects, place in a cold frame, and give a good watering through a fine rose. Keep the frame close and shaded from bright sunshine till roots are emitted.

Miscellaneous Bulbs.—Scillas should find a place in every garden. *S. sibirica*, *S. bifolia* and *S. verna* are all worthy of inclusion. *Chionodoxas*, too, following hard on the Snowdrops, should be freely grown. *C. gigantea*, *C. Luciliae* (Glory of the Snow) and *C. sardensis* are each little gems. Fritillarias are also highly decorative spring flowers. The varieties of *F. imperialis* (Crown Imperial) spring up as if by magic, followed by various other species, among which *F. meleagris* (Snake's-head Fritillary) is specially worthy of commendation. Then there are the Snowflakes and the Dog's-tooth Violets (*Erythronium Dens-canis*). Among not too hardy but highly desirable things are the Camassias, *Anomatheca cruenta*, *Schizostylis coccinea* and the lovely *Ferrarias*, a collection of

which has been charming us here from day to day for weeks.

The Rose Garden.

Garden Roses.—I am using this phrase in its widest sense, including Provence, Damask, Moss, Japanese, Scotch Briar and Sweet Briar. These old-fashioned Roses deserve more attention than they get nowadays, and I hope some readers will remember them when making up their Rose orders. A portion of the garden might be devoted to them, or they will be grateful for odd corners. Some of the stronger-growing species make a fine background for a herbaceous border. Most of them can be increased by suckers, and all by layers or cuttings.

Budded Stocks.—These must be looked over, and if the ligatures are too tight they should be slackened.

The Rock Garden.

Cutting Back.—No part of a garden will, if left alone, give quicker evidence that the law of "the survival of the fittest" (e.g., strongest and coarsest) is still operating than the rockwork; hence the necessity for constant vigilance. *Cerastiums*, *Antennarias*, *Thymes*, *Arabises*, *Aubrietias*, *Saxifrages* and a host of other things require cutting back from time to time, and the present is an opportune period for a thorough overhauling, so that the more compact subjects may get the full advantage of the deluging sunlight and have a free circulation of air round them during the winter months, thus saving many of them from damping off.

Plants Under Glass.

Crinum.—As these go out of flower, water should be gradually withheld till they are thoroughly dried off.

Paneratiums.—After blooming, these should have less water, but they do not require an entire rest like the *Crinums*.

Gloxinias.—Plants that flowered during the summer will now have gone to rest. If not required, they should be thrown away; but if to be retained for another season, they may be stored away for the winter where the temperature does not fall below 50° to 55°.

Pelargoniums.—As soon as the plants have started into growth they should be repotted, stood in a cool pit or frame and kept rather close for a week or ten days. Use pots a size less than those which the plants occupy at present. Trim the roots with a sharp knife. Do not use a very rich soil; pot firmly.

Fruits Under Glass.

Early Vines.—These must now be induced to go naturally to rest by maintaining dry conditions, with a free circulation of air. Should cold, wet weather occur, however, a little fire-heat should still be applied to maintain a buoyant atmosphere.

Peaches.—As these begin to shed their leaves naturally, the process of defoliation should be accelerated by going over the trees lightly with a new Birch broom, brushing from the stem towards the extremities of the tree.

Wasps.—Traps must be set for these wherever there is ripe fruit. Bottles partially filled with sour beer and sugar and hung on the trellises prove very efficacious.

The Vegetable Garden.

Late Cauliflowers.—Cauliflowers enjoy moist conditions, and if dry weather occurs it may be necessary to water the late crops, especially on light soils. Sutton's Mammoth, when liberally grown, gives grand results in autumn.

Late Peas.—Peas have done remarkably well this season to date, but it is during the next six weeks that the difference between liberal and stingy treatment of the Pea becomes apparent, and that both as regards yield and quality. Where the crop has received but little attention, the loss can still be retrieved to some extent by applications of liquid manure.

Harvesting Herbs.—Mint, Sage, Thyme, Marjoram and other herbs which are likely to be asked for during the winter should on a dry day be cut, bunched up and hung in an open shed to dry.

Seed Potatoes.—As these are lifted they should be spread out for a week or so to "green" prior to being stored away in trays. A pit is possibly the best place to store Potatoes for the table, but it is the worst wherein to store them for seed.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

ROSE GARDEN.

ROSE RAYON D'OR FOR BEDDING (E. B.).—Our experience of this lovely Rose is that it makes a splendid bedder, providing good, healthy, British-grown plants are obtained. Its blooms are carried erect, and its colour is well maintained. The very oldest blooms pale, but not before they are ready for removal, and there are always numerous buds to take their place. The glistering foliage, so wonderfully free from pests of all kinds, is a specially good trait of these pruniflora Roses. You would find the variety named above, also Arthur R. Goodwin, Cassie-Easlea and Louise Catherine Brasher real gems, Roses that would make a delightful bed of themselves, all having a similar growth and the same striking foliage. Yes; Silver Moon is a wickstrawiana climber, but it could be trained horizontally to form a low hedge. We should suggest, however, for this purpose such a Rose as Simplicity. Silver Moon is quite free from mildew, as far as our experience goes.

ROSE EARL OF WARWICK BLIGHTED (M. G. D.).—This Rose has a most peculiar habit of producing wood such as you send. We do not believe it is caused by fungal disease, but is simply a peculiarity of this variety. In our opinion the excessive use of artificial manures has much to do with it, also in the production of black spot and other diseases. We have noticed it very frequently upon beds that have been heavily manured. We have much faith in the formaldehyde remedy, if followed strictly upon the lines advocated by Dr. Waddell in the National Rose Society's Annual. We would, however, advise you to replant the bushes, taking care to spray the roots and wood when the work is done in November. See that the soil is of a good loamy nature, and add some lime if necessary. It may be your Rose-beds would benefit greatly by liming in October. If they have been heavily manured for some years, this is all the more necessary. A writer some time ago gave as a remedy for black spot an application of salt every two weeks, 4oz. of salt to three gallons of water. You might try this on a few plants, spraying them thoroughly. We think the scorched appearance of the foliage may be caused by the formaldehyde. All these sprays are best done in the evening.

THE GREENHOUSE.

BEGONIAS GOING WRONG (H. B.).—We had no fungus or insect on the Begonias to which the damage done can be attributed. We are inclined to think your compost may be too rich and does not contain sufficient sharp sand to make drainage efficient. Special care when watering must be exercised, and no doubt the plants will to some extent recover.

FUCHSIA LEAVES CURLED (R. S. M.).—There is no doubt that the unsatisfactory condition of your Fuchsias is due to an excess of stimulants, for you have been far too liberal in this respect. An application of Clay's Fertilizer once a fortnight would be quite sufficient unless it is given very weak indeed. It is quite probable that the mulching of manure would be ample without using Clay's Fertilizer at all. We certainly advise you to discontinue the excessive use of stimulants; but even then it is possible that the plants will take some time to recover, as very likely the roots are in a poor way. The condition of the leaves on the pot plant grown inside points to an error in cultivation of some kind, but what that is we cannot say. You did quite right in binding up the wounded portion of the stem with clay.

SPIRÆAS AFTER FLOWERING (Hants).—After the Spiræas had finished flowering, the old spikes should have been cut off and every encouragement given to the plants to make good growth. An occasional dose of liquid manure would then have been of great service, as in this way the plant is enabled to build up its strength and form flower-buds for another season. By drying off prematurely the constitution of the plant is greatly weakened, and, however treated now, you are not likely to have many flowers next year. However, you may even now feed the plants occasionally, and encourage growth till they naturally go to rest in the autumn. The best time to pot clumps of Spiræa for winter flowering is early in November, but in a roof greenhouse you cannot expect to have them in bloom by Christmas.

FRUIT GARDEN.

MANURING GOOSEBERRY BUSHES (Grey Stoke).—Yes? Gooseberry bushes are greatly improved by a liberal application of rotten manure to the soil about their roots in autumn. The crop is heavier and the fruit finer as a result. You are doing quite right in planting your Currant trees in the open (never mind your neighbour in this case). Dig a liberal dressing of rotten manure into the soil before planting. Your Black Currant trees are suffering from what is commonly called the big bud; the swelling is caused by a small mite or insect. The best cure for it is to pick off the diseased buds and burn them and the mites together. Your trees will go on bearing well, in spite of the disease, for many years if they are well looked after.

KITCHEN GARDEN.

HORSE-RADISH FOR SAUCE (H. H. C.).—The early autumn, when it is seen that the leaves of the Horse-radish are maturing, would be the best time to lift and store the roots for your purpose.

CARROT GRUB (Gardener). The simplest and most certain way is by burning the soil. In the autumn, in dry weather, make a strong wood fire on the piece of ground you wish to grow Carrots on next year. After it is well lighted, cover it over a foot thick with soil. Let this soil become hot enough to kill all things which have life in them. You will soon find out the necessary heat; then take off the soil, make up the fire anew, and cover with soil as before. Burn all the soil wanted for the Carrot crops a foot deep, and you will be rid of all grubs and all seeds of weeds as well.

MISCELLANEOUS.

RENOVATING A LAWN (Hants).—You can do a little good to your tennis lawn by dressing it with good loam and bonemeal in October, but it is doubtful whether the grass will become really good for a number of years; and although it means a considerable amount of work, it would be very much better and cheaper in the end to remove some of the soil and make up with better material. It is always a mistake to remove a considerable depth of surface soil and sow seeds or plant upon ground which has been some distance below the surface.

NAMES OF PLANTS.—G. E. Somerset.—Acanthaceae scrotopera.—Sedum.—Eriogonum canadensis.—C. R. Grouse-shoot.—Sedum saxangulare variety.—Rheumat.—Digitalis lutea and Thyma plicata.—T. C. A.—Androsace lanuginosa.—Buxton.—Rose Lamarque.—Enquirer.—The coppery Rose is Jean Ducher and the paler one G. Natoumand.

SOCIETIES.

SHREWSBURY SHOW.

The very first thing that every observant visitor must have said to himself "or otherwise" (to copy the phraseology of a quaint notice annexed in the firework and aerobatic part of the grounds) was: "This thirty-ninth show is larger, better and more varied than ever—a regular 'Chelsea' in Shropshire—even to the rock gardens." Then, after a somewhat cursory "run round" (to use a most inappropriate expression for the ordinary being who entered with the crowd of subscribers at 11.30), he would be aware of a quite exceptional display of Roses and Sweet Peas; of magnificent specimen flowering plants of titanic proportions, of mimicking Begonias which nearly out-roosed the Rose and quite out-camelliated the Camellia; of Carnations and Gladioli galore; of the eternal "touch the button and I will do the rest" sort of impossible airy and light decorated tables or table decorations; and of that visitor-fluttering and irradicable propensity of Shrewsbury which invariably thinks that every pair of eyes belongs to a mind of more than encyclopedic knowledge of genera, species and varieties, and cannot understand that there are just a few visitors like Sir Harry Vetch and Mr. E. A. Bowles and Mr. Farrer who do not know quite everything when they see it; and last, but not least—to end this little digression—that the society has been fortunate in securing in the person of Mr. W. G. Brazier a secretary who will prove himself to be a worthy follower of those veteran chiefs, Messrs. Adnutt and Naunton, who have now retired after thirty-eight years' service, and who were in the course of the opening day so signally honoured by Horticulture. In the competitive classes on the floral side of the show we noticed that the usual prize-winners were still to the fore, and that the different classes occupied much the same positions; so it will be convenient to deal with them as far as possible as they were grouped in the various tents; but in place of our more usual custom of dealing with individual exhibits, we propose to concentrate on what we consider their more prominent features.

LABELED TENTS.

Here there were the usual displays of groups of stove and greenhouse flowering and foliage plants, in which Crotons, Orchids, Abutilons, Palms and Bamboos played a leading part. There was a wealth of costly and varied material introduced in the different exhibits, but on the whole there was little originality or breaking away from the stereotyped ideas of former years. In the open class the names of Messrs. J. Cypher and Sons, Sir G. H. Kenrick and Mr. W. R. Manning of Dudley were to the fore, while in that confined to the county of Salop only, Mr. Bernard Howson of Market Drayton, Mr. A. M. Barber of Wellington

and Mrs. F. Burd of Shrewsbury occupied the chief positions. We were much struck with Mr. Barber's arrangement of simple green and white, with just a splash of orange introduced here and there to give piquancy to the whole. Although it was only awarded a second prize, we thought it compared very favourably with the more conventional bizarre group of the winner.

Class 4, for a group of hardy plants and aquatics, produced one of the most striking features of the whole show in the first-prize collection of Messrs. Gunn and Sons of Olton. The design was excellent. It consisted of a small central pool of water, with Water Lilies flanked with Ferns, and a single group of bluish Spiræa at one end; then, in a semi-circle round it, suggesting a garden path, a wide edging of grass to a slightly-raised border of perennials, in which Hollyhocks, Campanula pyramidalis, Hyacinthus candicans and Lythrum salicaria Rose Queen were featured, but which contained many other pleasing flowers, among which might be mentioned Gladiolus Primrose Queen.

The classes for large and small specimens are peculiarly Shrewsbury's own, and we look on Messrs. Cypher's grand plants as friends whom we would sadly miss if they did not occupy their accustomed places at the show. Their examples of Statice profusa, Erica autumnata, Erica ewersiana, Ixora Dulini and Statice Gilberti were veritable triumphs of horticultural skill. In the 10-inch pot class, Alhamanda Williamsii and Ixora Regina were two charming young plants that doubtless in time will be promoted to the larger class.

In this large tent Messrs. Mair and Sons provided a rich treat to Gladiolus lovers in their first-prize collection of twenty-four varieties—Sphinx amaranth, Sorcer (dried orange red), Mars (red), Snow Wreath (pure white) and Alexander (pink) stood up bravely as the fringe-line of a fine, well-equipped squad. Here, too, were what we advisedly called the mimicking Begonias of Messrs. Blackmore and Langdon of Bath and Messrs. Ware of Feltham, for anything more like Roses and Camellias it is hard to imagine. Undoubtedly the tuberosus varieties have reached a high standard of perfection; such sorts as Princess Victoria Louise (pink), Mrs. R. Caulfield (shell pink), Lady Dorrington (white), Rose Superbe (rose), Marjorie Donald (waved warm flesh), Mrs. W. L. Ainslie (waved yellow) and Mrs. Robert Morton (lemon and bronze yellow) were some that caught our eye in the Bath firm's exhibit. Begonia martiana grandiflora reminded us of an old-fashioned Balsam in its general appearance, and would be a welcome addition to the conservatory. It is very effective as a bedding plant. Messrs. Ware had Prince John, Lord Popetoun, Lady Cromer and King George V.—all good things that we can recommend.

ROSE TENT.

The whole of the staging in the centre of one of the tents was given up to Roses, which, in their first freshness, were exceedingly lovely. Great pillars and arches of the best ramblers, with solid masses of one variety, were the groundwork of almost all the competitive groups, while, as filling up, there were smaller bunches, baskets or vases of a bewildering number of appealing beauties.

Messrs. Gunn and Sons won the £10 prize and silver Champion Bowl with a well-arranged and most attractive collection, in which were good examples of Hugh Dickson, George C. Ward, The Lyon Rose and Gottfried Keller, the beautiful semi-double Briar, pale yellow centre, with the outer half of the petals a pale warm pink.

Messrs. Hugh Dickson, Limited, staged some glorious blooms. Among those that appealed to us were William Cooper (real old rose), Charming (warm pink), Ulster Glow (a large pale pink single), King George V. (deep dark rose) and Muriel Dickson (light shade of cerise). The variety Beauté de Lyon, so much beloved by our French friends, and awarded by them such signal honours when they saw it growing in their trial grounds at Bagatelle, was finely shown by Messrs. W. and J. Brown, and many were the expressions of wonder which we heard at its wonderful shade of coppery orange. The third prize in the champion class went to Mr. J. Mattock of New Headington, Oxford, who had Duchess of Wellington (yellow), Rayon d'Or and Irish Elegance well represented in large clumps of fine blooms.

SWEET PEAS.

When Mr. Thomas Stevenson says that Mr. Thomas Jones of Bryn, Pen-y-lan, Ruabon, never staged finer blooms than those which were to be seen in No. 4 Tent, readers will know that this exhibit of Sweet Peas was something out of the common. Had his Mark's Fox been a day older, the exhibit would have been well-nigh perfection. Wales may be worsted at football, but not at Sweet Pea growing as long as the redoubtable "Tommy" enters the lists. We congratulate him on what was one of the best things of the show. Following in his wake were Mr. J. Haycocks of Wrexham and Mr. G. H. Garnett of Skipton.

The smaller classes for twelves and sixes were well filled, the first prize winners being Mr. Robinson of Kington and Mr. J. Roberts of Gresford in their respective classes.

CARNATIONS.

Between the competitive and non-competitive groups the Carnations made a brave display. For a collection arranged in a space 15 feet by 4 feet Mr. C. Wall of Bath was placed first. We greatly admired his rosy pink Lady Fuller and white-petaled Princess, not only on account of their colour and form, but because they have the true Old Glove scent. Both are good winter-blooming varieties, and not too large. We can highly recommend them. Messrs. Young and Co. of Cheltenham, Mr. C. H. Herbert of Birmingham and Messrs. A. R. Brown and Co. of King's Norton were also prize-winners in the Carnation classes.

ROCKERIES.

These were a novelty for Shrewsbury. In spite of the handsome prizes which were offered (£50, £30 and £20) there were but three competitors. One of these had placed a certain quantity of stone among the flowers. *Lilium auratum* is certainly not the most appropriate plant to introduce into such compositions, and we think the judge was lenient to award the exhibit any prize at all. Messrs. T. R. Hayes and Co. of Keswick were placed first, and Mr. J. Wood of Boston Spa second. The latter had a much weaker exhibit than we have been in the habit of associating with his name. Bare patches of oyster-shell-looking stones, a too symmetrical-shaped pool, and a distinct sparseness of plants in certain parts where, we think, they ought to have been, were some of its obvious defects. The prize-winners had a more pleasing and better furnished exhibit.

VARIOUS.

Table decorations, bouquets and vases were present in considerable numbers, but there was nothing of special note in any of them. There were a few exhibits of summer-flowering Chrysanthemums. That of Mr. G. Bowness contained well-grown flowers, but was badly staged. We might mention Mrs. W. Sydenham (rich brown-maroon), Mrs. J. Field (golden brown) and Cynthia (pink) as good.

The bunches of hardy and greenhouse cut flowers were much as usual, but sadly wanted naming in many instances. Dahlias were not very numerous, but there were some beautiful Cactus varieties in Messrs. Boffamley and Burton's collection, and some excellent Peony-flowered ones were in that of Messrs. Keynes, Williams and Co.

FRUIT.

There is no horticultural exhibition in the kingdom at which exotic fruit grown under glass is so largely or so well grown as at Shrewsbury, or at which it is more attractively displayed for the enjoyment and appreciation of the vast number who year after year visit this great show. The quality of these fruits, and especially Grapes, is more or less dependent on the conditions of weather the season presents. The conditions this year, to a marked extent, have left their mark on Muscats and white Grapes generally, in so far that good colour and finish are lacking. This was made patent at this show, and it may also be said that quality throughout the fruit classes, with few exceptions, compared unfavourably with the best seen at Shrewsbury in some previous years.

Class 53, champion decorated fruit tables: The establishment of this class, where fruit and flowers are combined in the arrangement of the tables, was a happy thought on the part of the committee of this show, and has proved to be most popular. There is not a more beautiful or attractive class in the show than this. The conditions which govern it are as follows: The tables are 10 feet by 4 feet 3 inches, and covered by a white cloth. Thirty dishes of fruit are demanded in not less than nine distinct kinds. Not more than fourteen bunches of Grapes are allowed, and in not fewer than four varieties (including black and white), and not more than four varieties of any other kind of fruit, or more than two dishes of any one variety. On this occasion there were three exhibits in competition, the first prize (£25) going to the Duke of Westminster (gardener, Mr. Barnes); second (£20), Lady Henry Somerset (gardener, Mr. Mullins); third (£17 10s.), the Earl of Harrington (gardener, Mr. Goodacre).

The next fruit class in importance, Class 54, was that for a collection of Grapes, twelve bunches, in four or more distinct varieties, but not more than four bunches of any one variety. Point judging was insisted on in both of these collections, and cards displayed showed the points received by each dish exhibited. As previously mentioned, there was nothing remarkable in the high quality of the Grapes to call for special notice, but evidently it was quality and high finish rather than size which weighed with the judges in deciding the awards. There were eight competitors in this class, collectively a grand exhibition of Grapes. The first prize (£20) went to the Duke of Newcastle (gardener, Mr. Barker); second (£16), Lord Rowallan (gardener, Mr. Dixon); third (£9), the Earl of Harrington (gardener, Mr. Goodacre); fourth (£6), Lady Henry Somerset (gardener, Mr. Mullins).

Class 55, collection of twelve dishes of fruit, twelve distinct varieties, not more than two varieties of a kind, Pine-apples excluded: First (£10), the Duke of Newcastle; second (£6), E. Bewley, Esq., Rathgar, Dublin (gardener, Mr. McIntosh).

Class 56, collection of nine dishes of fruit, nine distinct varieties, not lower than seven kinds and not more than two varieties of a kind, Pine-apples excluded (open to the county of Salop only): First (£5), Captain Heywood-Lonsdale; second (£4), Colonel Mainwaring Jackson; third (£3), Mr. A. Heber Percy; fourth (£2), Major-General Sir Francis Lloyd.

Class 57, four bunches of Grapes, two bunches of black and two bunches of white: First (£6), Captain Heywood-Lonsdale; second (£4), Colonel H. C. Leigh; third (£3), E. Bewley, Esq., Dublin.

Class 58, two bunches of Black Hamburg Grapes: First, the Earl of Harrington; second, Lord Rowallan; third, Lady Henry Somerset.

Class 59, single bunch of Black Hamburg Grapes: First, Lord Rowallan; second, H. St. Maur, Esq.; third, the Duke of Newcastle.

Class 60, two bunches of black Grapes, Muscat variety: First, the Earl of Harrington.

Class 61, two bunches of Madresfield Court Grapes: First, Colonel H. C. Leigh; second, the Earl of Harrington; third, Mr. J. Branton, Stourport.

Class 62, two bunches of Alicante Grapes: First, Lady Henry Somerset; second, Lord Joyce.

Class 63, any other black Grape: First, Lord Rowallan, with Gros Maroc; second, Lady Henry Somerset, with the same variety.

Class 64, two bunches of white Muscats: First, Lord Swarforth, Braham Castle; second, the Duke of Newcastle; third, Hugh Andrews, Esq., Winchcombe.

Class 65, two bunches of white Grapes, any other variety: First, the Duke of Newcastle; second, Mrs. F. Alderson; third, Sir Howell Davies, M.P., Stoke Bishop.

Class 66, two bunches of Black Hamburg Grapes (open to the county of Salop only): First, Lady Mary Herbert, Market Drayton; second, Captain Heywood-Lonsdale; third, Mrs. F. Alderson.

Class 67, Madresfield Court Grape (county of Salop only): First, Captain Heywood-Lonsdale; second, Colonel Mainwaring Jackson.

Class 68, black Grape, any other variety (Salop only): First, Colonel Mainwaring Jackson; second, Mrs. F. Alderson.

Class 69, white Muscats (Salop only): First, Captain Heywood-Lonsdale; second, Major R. A. Nowill.

Class 70 (Salop only): First, Mrs. F. Alderson; second, Captain Heywood-Lonsdale; third, Colonel M. Jackson.

SINGLE DISHES OF FRUIT.

Class 73, Peaches, a dish of eight: Here there was a large entry, but no exhibit calling for special remark except the first-prize dish from the Duke of Westminster, the variety being Belle-garde. This was exceptionally fine. Second, Lady Henry Somerset.

Class 74, Nectarines, a dish of eight: First, Egerton Leigh, Esq.; second, the Duke of Newcastle; third, the Earl of Harrington.

Class 75, Apricots: First, A. S. Hughes, Esq.; second, R. A. Nowill, Esq.; third, the Earl of Harrington.

Class 76, green-fleshed Melon: First, Lady Henry Somerset; second, Miss Baird; third, Egerton Leigh, Esq.

Class 77, scarlet-fleshed Melon: First, Colonel H. C. Leigh; second, Colonel Mainwaring Jackson; third, Miss Baird.

Class 78, Melon, any other variety (Salop only): First, R. L. Kenyon Pradoc, Esq.

VEGETABLES.

Taking into consideration the great drought which the country generally has passed through this summer, vegetables made a brave and, indeed, in many instances a wonderfully fine show. Competition was unusually keen in many of the classes, point judging in some classes being demanded. This is a mistake, we think. It should be left optional for the judges to resort to this when the competition is extra close.

Class 88 (prizes offered by Robert Sydenham, Limited, Birmingham), collection of vegetables, nine distinct kinds: First (£10), F. Barrett, Esq.; second (£5), Lord North; third (£3), E. Deakin, Esq.; fourth (£2), W. G. Robinson, Esq.; fifth (£1), J. H. Pugh, Esq.

Class 89 (prizes offered by Messrs. Sutton and Sons), collection of nine distinct kinds: First (£8 8s.), Captain Spenser Clay, M.P.; second (£6 6s.), Lord North; third (£4 4s.), Hugh Andrews, Esq.

Class 90 (prizes offered by Messrs. James Carter and Co., London), collection of six distinct varieties: First (£6), Mr. Barnett; second (£4), Mr. E. Deakin; third (£3), Mr. H. Pugh; fourth (£2), Mr. W. Robinson; fifth (30s.), Colonel Cornwallis-West.

Class 91 (prizes offered by Messrs. Webb and Sons, Stourbridge), collection of nine distinct kinds: First (£7), Mr. E. Winchester; second (£5), Mr. Hugh Andrews; third (£3), Mr. B. Watson Smith; fourth (£2), Mr. A. F. Rainbow; fifth (20s.), Messrs. Howell; sixth (£1), Mr. W. E. Hyde.

Class 92 (prizes offered by Messrs. Chibran, Manchester), collection of nine kinds of vegetables: First (£8), the Marquis of Northampton; second (£4), T. Sanderson, Esq.; third (£3), F. R. Dixon Nuttall, Esq.; fourth (£2), Crawford Logan, Esq.; fifth (£1), A. E. Humphrys Owen, Esq.

Class 93 (prizes offered by Messrs. Dickson and Robinson, Manchester), collection of nine distinct vegetables: First (£8 8s.), the Marquis of Northampton; second (£6 6s.), Mr. T. Jones, Ruabon; third (£4 4s.), F. R. Owen, Esq.; fourth (£3 3s.), Captain H. Lonsdale; fifth (30s.), Miss Longworth; sixth (£1), Captain H. Spenser Clay, M.P.

THE SOCIETY'S OPEN CLASSES.

Class 94, twelve distinct kinds: First (£7), the Hon. Vicary Gibbs, Aldenham (gardener, Mr. Beckett), a superb exhibit; second (£5), Hugh Andrews, Esq.; third (£3), T. Sanderson, Esq.; fourth (£1), W. E. Hyde, Esq.

Class 95, collection of vegetables, nine distinct kinds (Salop only): First (£3), Mr. F. Bibby; second (£2), Captain H. Lonsdale; third (£1), Mr. A. H. Heber Percy.

There were also classes for the following, the competition in nearly all being keen and the quality generally excellent: Six dishes of Potatoes, six Tomatoes, brace of Cucumbers, dish of Peas, French Beans, Runner Beans, Cauliflowers, Celery, Parsnips, Carrots, Turnips and Spring Onions.

COTTAGERS' CLASSES.

Many of these were provided and liberal prizes given. They had a tent to themselves, and were not the least interesting section of the show. The exhibits here formed an excellent object-lesson of what cottagers can do in the way of producing first-class quality vegetables from their small plots or cottage gardens.

NON-COMPETITIVE EXHIBITS.

The Shrewsbury committee are fortunate in being able to secure year after year such valuable support from the

trade. This year these exhibits proved more numerous, important and beautiful than perhaps ever before. This was the opinion of the gentleman who made the awards in this section, and his estimate was endorsed by all we came in contact with who spoke on the subject. The exhibition would be shorn of much of its beauty were these grand exhibits absent.

Messrs. Sutton and Sons' collection was truly a rich and wonderful one of all the specialities of vegetables in season with which their name is associated, as well as many flowers and fruit, all magnificently grown and most artistically arranged. Large gold medal.

Messrs. J. Webb and Sons of Stourbridge.—This collection, which consisted of many flowers, fruit and vegetables, contained worthy specimens of this renowned great Worcestershire firm. The way this collection was disposed we thought was excellent and artistic. Large gold medal.

The Hon. Vicary Gibbs (gardener, Mr. Beckett).—A magnificent collection of vegetables, among one of the best Mr. Beckett has ever put up. Large gold medal.

The King's Acre Nursery Company, Hereford.—Their exhibit consisted of fruit trees in pots, mostly loaded with fruit. Apples and Pears we have seldom, if ever, seen bearing heavier crops of well-developed fruit. As well as Apples and Pears, the collection consisted of Grapes, Peaches, Nectarines, Plums, Figs, and also grand examples of gathered fruits in baskets. Large gold medal.

Messrs. James Veitch and Sons, Limited, Chelsea, London.—Of their grand exhibit of superbly-grown Chelsea (and especially their wonderful specimen Pitcher Plant), which filled a large recess in one of the principal tents, it may truly be said that seldom have lovers or growers of plants had the privilege of seeing so rich a collection as that presented. Large gold medal.

Messrs. Wallace and Co., Colchester.—This is the season of blooming of that most charming and beautiful flower the *Montbretia*. In this collection we were favoured with a view of the many new and beautiful varieties recently introduced, Star of the East being perhaps the most beautiful. Other cut flowers included in this collection were Delphiniums, Phloxes, Tritomas and Lilies. Small gold medal.

Messrs. Pipers, Baywater.—This firm had a most interesting exhibit of garden border flowers, artistically arranged, for which a small gold medal was awarded.

Messrs. John Forbes, Hawick, Limited.—This firm had an attractive exhibit of their specialities in the way of Pentstemons, Carnations, Phloxes, Gaillardias and Violas. Small gold medal.

Messrs. Dicksons of Chester.—This firm set up one of the handsomest exhibits of herbaceous border flowers and Roses we have seen for a long time. The arrangement in grouping was excellent and the whole most pleasing. Gold medal.

Messrs. Dobbie and Co., Edinburgh.—This exhibit consisted chiefly of a large collection of *Collarete* Dahlias, Sweet Peas and Roses. These were splendidly grown, and the varieties of the choicest and best. The arrangement and setting up of the plants were excellent, the whole well deserving the large gold medal the firm received.

Messrs. Dickson, Brown and Robinson.—This firm is always strongly represented at Shrewsbury, and this year they excelled themselves in the splendid collection of fruit, vegetables and flowers they set up. Large gold medal.

Messrs. Alex. Dickson and Sons, Newtownards, showed a large collection of beautiful and choice varieties of cut Roses, the climbing sorts arranged on arches with a base of show varieties supporting them. Large gold medal.

Messrs. H. B. May and Sons, Upper Edmonton.—This firm's superbly-grown and choice collection of Ferns was much admired, and amid such masses of brilliant colour it was quite a relief to the eye to turn to these for rest. Silver-gilt medal.

Mr. Henry Eckford, Wem.—A large, well-grown collection of Sweet Peas. Small gold medal.

Messrs. Hobbies, Limited, Dereham.—Among the most attractive groups of flowers was the one from this firm. It occupied a prominent position in one of the large tents, and consisted of *Collarete* and other Dahlias, also many of their beautiful weeping and climbing wickrariansa Roses. Large gold medal.

The following, among others, had medals awarded to their exhibits:

Messrs. Isaac House had Phloxes and alpine plants. Small gold medal.

Mr. J. R. Russell, Richmond, had a collection of Tree Ivies. These were grand, the finest we have ever seen. Small gold medal.

Mr. H. N. Ellison, West Bromwich, had a select and beautiful collection of well-grown greenhouse Ferns. Silver medal.

Messrs. Ker and Sons, Liverpool, were awarded a silver medal for a choice, well-grown collection of Crotons.

Mr. Maurice Prichard, Christchurch, Hants, received a silver-gilt medal for a very choice and beautiful collection of hardy herbaceous flowers.

Messrs. John Peed of Norwood showed a fine collection of Caladiums. Silver-gilt medal.

Messrs. Bakers of Wolverhampton had a well designed, arranged and planted rock and water garden. This firm obtained a large gold medal.

Mr. Amos Perry, Enfield, had an imposing and beautiful exhibition of hardy flowers and Water Lilies. This was awarded a large gold medal.

Messrs. Barr and Sons, Taplow, Bucks, staged a large and excellent collection of vegetables, admirably and attractively set up. Silver-gilt medal.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographs or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artists or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Our Special Bulb Number.—Now that the season for planting spring-flowering bulbs will soon be with us, we propose to devote our next issue mainly to articles on the subject. These will be of more than usual interest, such well-known authorities as the Rev. J. Jacob, Mr. E. A. Bowles, Mr. H. J. Elwes and Mr. Duman Pearson being among the contributors. The number will be considerably enlarged and fully illustrated, and in addition will contain a coloured plate of five new Narcissi. The price will be one penny, as usual.

Nepeta Mussini.—This now well-known member of the Catmint family is largely employed as an edging to several of the beds in the Old English Garden at Battersea Park. The edgings are broad and the *Nepeta* is admirably adapted for the purpose, as the greyish masses of leafage and the lavender blue spikes of flowers tend to give that feeling of restfulness that one may well associate with an Old English garden.

Preserving Everlasting Flowers.—Where such plants as *Helichrysums*, *Helipterums*, *Gnaphaliums*, *Ammobiums*, *Staticees* and other Everlasting Flowers are grown, they will now need to be watched if required for drying. They should be cut before the flowers have become fully expanded, tied in bunches and hung head downwards in a dry place. Grasses and the well-known *Physalis* (better known, perhaps, as Winter Cherries or Bladder Herbs) may also be treated in the same way.

A Beautiful Campanula.—One of the most showy *Campanulas* flowering at the present time, helping to extend the beauty of the rock garden, is *Campanula haylodgensis*, a hybrid possibly between *C. carpatia* and *C. caspitosa* (*C. pusilla*), raised some years ago at Haylodge, Edinburgh. This dwarf-growing plant, from 4 inches to 5 inches high, with bells of a lovely silvery blue, should be in every rock garden. There is a double variety of it, and although quite as showy as the type, but the flowers being heavier, it does not stand up so gracefully.

The Syrian or Tree Mallows.—Commencing to flower during August, the numerous varieties of *Hibiscus syriacus* (*Althaea frutex*) continue to produce a bright show of blooms throughout September. Although by no means difficult to grow successfully, the plants thrive best in a well-drained loam, with, during a summer such as that of 1913, a mulching of old manure in June and several thorough soakings of water at intervals. A few plants may worthily find a place in the shrubbery of a small garden, for the *Hibiscus* is quite a good town shrub. In cold districts they should be planted on a warm south or south-west border. The bushes, which are deciduous, vary from 4 feet or 5 feet in height to upwards of 20 feet

or more. Among the numerous varieties, which comprise a fairly wide selection of colours, the following are noteworthy: *Coloste*, single, rich blue; *Humabo*, single pink, dark centre; *paeniflorus*, double rosy red; *alba*, single white; bicolor hybrids, double white, maroon base to petals; *limba plena*, rich rosy red; and variegata, lilac flowers and variegated leaves.

National Rose Society.—The society's exhibition of autumn Roses will be held in the Royal Horticultural Hall, Vincent Square, Westminster, on Thursday and Friday, September 11 and 12. The charges for admission will be as follows: On the first day, from 1 p.m. to 4 p.m. 2s. 6d., from 4 p.m. to 6 p.m. 1s., and from 6 p.m. to 9 p.m. 3d. On the second day, throughout the day (10 a.m. to 6 p.m.) the charge will be 6d.

A Valuable Autumn-Flowering Rock Plant.—One of the most charming plants for the rock garden or for growing on old walls is *Erigeron micronatus*, a native of Mexico. It is very seldom met with, and yet always admired when seen. The dainty little Daisy-like flowers, which are borne in great profusion, are of a reddish tint, turning to pink till they are almost white by the time they are open. It is easily grown, and when once established seeds itself quite freely. If seeds of it are placed as soon as ripe in crevices along an old wall, it will quickly establish itself.

Antirrhinum Trials at Wisley.—Each year trials of flowering plants are made in the Royal Horticultural Society's Gardens at Wisley, but we very much doubt if any of the numerous trials have created a more brilliant colour display than the *Antirrhinums*, which are now at their very best. Speaking generally, the seedlings, which are under number, are very true to colour. Varieties of dwarf habit predominate, although it is pleasant to see that the taller-growing varieties, such as we associate with old-world gardens, are not left out. Orange, yellow and pink in delightful art shades of colour are much in evidence among the newer varieties; but the result of the trials is not yet made known.

Hardy Annuals for Spring Flowering.—Often during the spring there is a gap or scarcity of flowers between the bulbous flowering plants and the summer flowers. It is at this period of the year that annuals and biennials, sown at the present time, light up the garden with welcome masses of fresh and vivid colourings. At one time it was not recognised to any great extent to sow annuals at this time of the year, and even now they are not used to the extent they deserve. There are many quite suitable—*Corniflowers*, *Collinsias*, *Venus' Looking-glass*, *Starley Poppies*, *Lunanthuses*, *Virginian Stocks*, *Eschscholtzias*, *Larkspurs*, *Nemophila*, *Sweet Peas* and many others; in fact, all hardy annuals are worth trying, as they can be purchased for quite a small outlay.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose Irish Elegance.—With reference to "A. B. Essex's" question in your issue of last week, "Is Rose Irish Elegance free-flowering?" I can assure him that it most certainly is so. I was given a plant two or three years ago, and it has done very well with me. Ever since May I have had a continuance of blooms, and my plant would quite equal his picture as to flowers. The plant just now is covered with flowers and buds. The Rose is particularly suited for button-holes and for decoration in the early opening stage, but, alas! not later.—H. G. B., *Forest Hill*

Best Roses for Beds.—I am surprised to see "A. P." on page 408 recommending *Etoile de France*. I had a plant when it first came out, and I have had two blooms only that have opened fairly well. I thought it was acknowledged on all hands that it was no good for ordinary purposes. I should be delighted if "A. P." can teach me how to make its "hard-as-lead" buds open properly. Victor Hugo, I think, is hardly suitable for beds, as it is not a thoroughly good doer.—C. LEWIS ST. ADAMS

A Beautiful Hardy Lily. We think you may be interested in the enclosed photograph of *Lilium Sargentii*. It is one of the noblest of Wilson's Chinese collections, more vigorous than *L. regale* (or *microphyllum* as it is better known in gardens), and flowering two or three weeks later. It seems to be one of the very hardest species, and has a constitution comparable with that of *L. Henryi*. The flowers are milky white shaded outside richly with deep reddish brown and touched with yellow at the centre. The spike figured was 5 feet high and carried ten perfect flowers. It is an unusually beautiful specimen. The photograph was taken on August 20.—R. WALLACE AND CO.

Late-blooming Single Roses.—The illustration and interesting note of *Irish Elegance*, which appeared on page 430, reminds me that we now have quite a number of single Roses that flower late in the season as well as through the early summer months. Those who say that *Irish Elegance* is a poor doer and bloomer have not seen this grand Rose in anything like its true form. It is almost always in flower wherever I have met with it—early, mid-season, and until frost stops it here. The same firm (Messrs. A. Dickson and Sons of Newtownards) brought out a single white of exceptional merit in *Irish Beauty*—numerosity of pure white with bright golden anthers. *Irish Harmony* (saffron yellow) and *Irish Glory* (silvery pink) are others of great beauty; but the two standing above all are *Irish Elegance* and

Irish Beauty. At the time of writing (August 29) I have some fine standards of American Pillar and Delight well in flower on the eve of September, and likely to continue until the middle of that month. Muriel Jameson, Mrs. A. Kingsmill and Mrs. W. T. Massey, three newer varieties, are also good late in the season. Three semi-doubles in Maharajah, Gottfried Keller and Simplicity are to be depended upon for an autumnal display. A. P., *Uckfield*

Erica darleyensis.—With reference to the note signed "S. A." on page 430 of THE GARDEN for August 30 respecting the Heath commonly called *Erica mediterranea hybrida* or sometimes *E.*

A Pretty Combination.—A combination of plants which is rather effective here and may interest others is a bed of *Hydrangea hortensis* with a margin of *Funkia lanceolata*. The *Funkia* is extremely free-flowering, and the slender spikes of lavender flowers blend well with the pink of the *Hydrangeas*. The effect might be even better perhaps were the *Funkias* planted among the *Hydrangeas* as well as the edging.—E. G. DAVISON, *Westwick Gardens, Norwich*.

Rambler Roses and the Coming Winter.—If you would open your columns to a discussion on the best way of saving our ramblers from being cut off by frost, the lasting praise of many people—

both those who have large gardens and others who can grow but two or three of these lovely Roses—would be due to you. Early last November there was the severest frost of the winter on two consecutive nights. Result: All the wickiana ramblers—Dorothy Perkins, Lady Gay, Leuchstern, Trier, Crimson Rambler, Hiawatha, Gardenia and other favourites—were killed down to the ground. I believe the same thing happened all over Scotland and the North of England, except perhaps in a few warm positions on the West Coast. Thus the space the ramblers used to cover was left bare. The growth made during this, happily, warm summer can only fill parts of the vacant places and afford but a few samples of the blooms that should have beautified them. This is not the first time the ramblers have been cut down by frost. In the winter of 1910-11 a similar calamity occurred. Since then I have protected several pot ramblers by covering them with Bracken, but those suffered last November equally with the unprotected ones. Possibly there was not enough Bracken. The most widely-accepted theory seems to be that the frosts last November were so injurious because they came before the sap had retreated to the roots. It chanced that a comparatively large plant of a rambler had to be moved at the end of October, and it was not injured by those frosts. It is suggested that the shock of removal had sent the sap back; hence the immunity to frost. But in 1910-11 the frosts were not specially early. The questions that might be discussed are such as these: Would

LILIAM SARGENTII, A BEAUTIFUL NEW HARDY SPECIES FROM CHINA.

hybrida, I may perhaps be allowed to state that I have ventured to give it the above name in a forthcoming work on hardy trees and shrubs now in course of being printed. Apart from the objection of making a hybrid a variety of one of its parents, this Heath is really nearer to *E. carnea* than to *E. mediterranea*. *Erica hybrida* is a garden name that has long been used for the Cape Heath, *E. Massoni*, and as there is already an *E. Smithiana*, the name *darleyensis* appears to be the most appropriate one to connect this beautiful and very valuable Heath with the firm to whom we owe its existence.—Messrs. Smith of Daley Dale.—W. J. BEAN.

it answer to hit all the Rambler Roses at the beginning of winter? Has this ever been tried on a large scale as a preventive of injury by frost? How could large plants growing on pergola, trellis, &c., be lifted? Would it do to simply expose their roots for a day or two? Is the common practice of lifting *Brucedii* intended to stand the winter really analogous? If, on the other hand, some covering would be a more effectual protection, what would be the best covering and how should it be applied? Is there any other and better remedy? Are there any of these ramblers that would stand 20° to 25° of frost?—AMATEUR.

Anemone japonica Gracieuse.—For the information of your correspondent "C. C.," page 418, issue August 23, I may mention that this desirable variety of the Japanese Anemone emanated from Nancy, it being distributed by MM. Lemoine et Fils in the spring of 1908. Another variety sent out at the same time was Galathée.—H. P.

Fabiana imbricata.—The note regarding *Fabiana imbricata* on page 407 is one which is quite called for, as this shrub is not nearly well enough known. As stated, "it succeeds as a bush in the warmer counties, but must be planted against a wall elsewhere." In common with quite a number of plants from Peru and Chili, it does very well along the West of Scotland, where I know of several good plants, mostly against walls. There it pulled safely through the past winter—one of the most disastrous to shrubs for many years. It grows and flowers well against a wall in Edinburgh also, but the West of Scotland is evidently better suited to it than the East.—S. ARNOTT.

Lilium Brownii.—This beautiful trumpet-shaped Lily, so well illustrated in *THE GARDEN* for August 16, is seen to better advantage when in the open ground than it is if grown under glass for greenhouse or conservatory decoration. A very prominent feature is the way in which the exterior of the blooms and the unopened buds are tinged with chocolate. This is far more pronounced when the plants are growing outside, fully exposed to light and air, than if they are brought on under glass. For this reason, when the flowers are needed for greenhouse decoration, a good plan is to grow them outside till the blossoms are on the point of expanding, and then to take them under glass. This has its advantages in more ways than one, for in a shaded structure the flowers last longer than they do in full sunshine, while out of doors, if the weather is showery, the spotless interior of the blooms is often sullied by the coloured pollen, which does not happen with glass protection. One feature concerning *Lilium Brownii* is always a puzzle to me. We are told by the various authorities that it is a native of China, which it may be, for closely-allied kinds come from that region; but I have never seen *Lilium Brownii* as grown in gardens and nurseries for so many years among any Chinese importations, though very large numbers have come under my notice. This Lily as grown by the Dutch has not shown the least variation during almost the half a century that I have been acquainted with it. Certainly, appearances point to it being a Chinese kind, but the fact remains that it is different from any recent importations.—H. P.

Midland Daffodil Society.—As the Royal Horticultural Society have responded to so large an extent to the wants of those who advocated a National Daffodil Society, and, consequently, the foundation of such a society is likely to be postponed *sine die*, may I urge the claims of the Midland Daffodil Society to the support of all lovers of Daffodils and the advantages that such membership confers? First, the society (owing greatly to the energy of the late Mr. Robert Sydenham), after struggling in its early days, now holds the premier position among Daffodil societies, and its shows have done very much to encourage and popularise the love of the Daffodil, a knowledge of what the capabilities of the flower are. Consequently, I think a debt of gratitude is due from all lovers of the flower, and especially from those who are hybridisers, as its shows have been the means of more new seedlings being shown and seen than

has any other society's show. Secondly, membership means (1) joining the leading club of the Daffodil world and bringing a member into touch with those who are the busiest workers among the Daffodils; and (2) the right to attend and exhibit at the shows, which are acknowledged to be the pleasantest gatherings of the kind, and where the leaders in the cult are always to be found with the latest up-to-date flowers. The subscription varies from 5s. to £2 2s., and the number of tickets to which members are entitled varies accordingly. With a larger membership and more funds at command, more could be done by the committee on the lines of the suggestions by those in favour of a National Society. I would ask all lovers of the Daffodil who are not already members to write *now* to Mr. Herbert Smith, Secretary of the Midland Daffodil Society, Tenby Street, Birmingham, intimating their willingness to join the society.—C. LEMESLE ADAMS.

The Best White Rose for Bedding.—A friend wants me to give her the name of the best white Rose for bedding. It is wanted for a bed (one of seven in a sunken Rose garden, each taking about twenty-five plants), and is to replace Frau Karl Druschki, which is being discarded, largely owing to its too vigorous growth and ungainly habit, being out of harmony with the occupants of the other six beds. The question, although apparently a simple one to answer, is really not so. Cream and flesh tints are not desired, as they are represented already, and that rules out such Roses as Pharisæer, Ethel Malcolm, La Tosca, Mrs. David McKee and Antoine Rivoire, even if the habit of the first three named is not too vigorous. Fortunately, Teas do exceptionally well in her soil, and I have suggested Molly Sharman Crawford or Mrs. Herbert Stevens; they are certainly "possibles." Mrs. H. Hawksworth and British Queen would have been considered, but their price forbids. Lady Quartus Ewart, Marjorie Edelstein and Amateur Teysier also occurred to me, but the mere mention of their names in connection with the best white Rose is sufficient to rule them out. There is White Killarney, and also Simplicity and Irish Beauty; but the last two are not desired, and White Killarney is too subject to mildew. I can think of nothing else so good as the two Teas Molly Sharman Crawford and Mrs. Herbert Stevens, but my friend seems to think there should be something better than either. The first is hardly free enough, and the second, which is preferred, does not hold its flowers erect. Can any of your numerous readers help her and me out of the difficulty, or can you, Mr. Editor, suggest something better than either? Rugosas, Chinas and Polyanthas are barred. Perhaps "Danecroft" will give us the benefit of his wide experience. A person friend to whom I put the query suggested Sunburst! But then he was joking.—HERBERT E. MOLYNEUX.

FORTHCOMING EVENTS.

September 8.—United Horticultural Benefit and Provident Society's Meeting. National Chrysanthemum Society's Floral Committee Meeting.

September 9.—Royal Horticultural Society's Meeting and Exhibition. National Dahlia Society's Show at the Crystal Palace (two days).

September 10.—Royal Caledonian Horticultural Society's Show (two days).

September 11.—National Rose Society's Autumn Show at the Royal Horticultural Society's Hall (two days). Messrs. Dickson and Robinson's Vegetable Show at the Manchester Coal Exchange (two days). Paisley Horticultural Society's Show (two days).

NATIONAL DIPLOMA IN HORTICULTURE.

LAST year the Council of the Royal Horticultural Society approached the Board of Agriculture with the view to the founding of a Diploma of Horticulture, a proposal that the Board agreed to, and Government authority was given for the title "National" to be used. Those who are keenly interested in horticulture felt that this was a step, even though a small one, in the right direction, and awaited with interest the proposals for the examinations that should enable the Council to say who was a fit person to hold such a diploma. As stated in our last issue, these particulars have now been issued, and after carefully perusing them we do not think they will be received with open arms by the gardening community.

It seems to us that the conditions laid down will preclude most of the best gardeners of to-day from obtaining the diploma, even if they desired to do so. Under paragraph 4, *b*, candidates are to give some documentary evidence of the sufficiency of their previous general education; and in the following paragraph we are told that the certificate of the College of Preceptors, the Oxford and Cambridge local examination boards, matriculation at any British University, or any similar certificate which may from time to time be approved by the Council of the society will be accepted as evidence. Failing such documentary evidence, candidates must submit themselves to (and pass) a qualifying test established by the society in the subjects mentioned in Syllabus 1. Two paragraphs in this syllabus state that the candidate must show an acquaintance with arithmetic up to and including decimals and elementary mensuration, and have a general elementary knowledge of geography, such as the relative positions of the principal countries of the world, with some knowledge of their climates and of the causes which determine climate. Knowledge of such subjects is, of course, useful in a way; but we wonder how many of our best gardeners, florists, fruit-growers and seedsmen, or members of the society's own committees, could pass such a qualifying test.

However, once it is passed, the candidate gets down to more practical topics, and has to pass a preliminary examination, the syllabus for which appears to have been well thought out. We are glad to see that it is to be mainly of a practical character, as, in our opinion, written answers to questions are no real test of a person's abilities in gardening. Having passed this preliminary examination, which is essential, the candidate is not entitled to a diploma, but must sit for a final examination, particulars of which are not given.

The entrance fees, which are payable in advance, are £1 for the preliminary examination and £3 for the final examination. These, we think, are much too high, and will prevent many for whom the examinations are professedly to be held from entering. We are fully alive to the fact that the holding of such examinations will entail considerable expense; but surely a wealthy body such as the Royal Horticultural Society, which exists for the advancement of horticulture, can arrange better terms than these for young gardeners. To get the best *practical* men to sit for the diploma it will, we feel certain, be necessary to modify the qualifying test and to reduce the examination fees.

THE FRUIT GARDEN.

SEASONABLE NOTES ON PEACHES.

DURING the month of September amateur cultivators will have many fruits ripening on open walls and in unheated houses. If there are more fruits than can be used at home, and the surplus ones are sent to market or to friends at a distance, careful gathering and packing are very essential to success. It is always best to gather the fruits for such purposes before they are quite ripe. When gathering, place two fingers and the thumb of one hand at the base of the fruit and thus remove it from the branch. Never touch the sides of the fruits. If they are pressed and are, at the time even, unripe, the flesh will be badly discoloured when ripened.

Wooden boxes, 3 inches deep, made to hold six, twelve or twenty-four fruits, are the best in which to pack Peaches. Half-inch wool is strong enough. Wood-wool or cotton-wool, unbleached, may be

—where overcrowding occurs—from which the fruits have been removed must be cut out now.

Watering.—It is a fact that many Peach trees are sadly neglected after the fruit has been gathered. If the soil is allowed to get dust dry, the buds fall off wholesale in spring when the sap once more becomes very active. Thoroughly soak the border soil several times this autumn before it becomes too dry, and open the ventilators and doors to admit plenty of air. G. G.

THE GREENHOUSE.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

PLANTS growing in the flower garden will now be well studded with buds, and if fine blooms are preferred to sprays of small flowers, no time should be lost in carrying out the work of disbudding the plants. Some varieties are more suitable for disbudding than others, and certainly many sorts look better bearing

rather small pots, and neatly staked. If some plants of the same variety are placed in positions facing the north, or on the north and east sides of walls, the season of flowering of that variety will be prolonged by about ten days.

How to Retard Exhibition Blooms.—Nearly all inexperienced cultivators defer the attempt to retard the early blooms until the latter are more than half developed. At that stage it is quite possible to keep them back a week without any loss of colour or freshness of floret; but the best time to retard the forward varieties is before the colour of the flower petals can be seen. By placing the plants in open but cool positions until housing-time comes, the progress of the buds will be considerably arrested; indeed, to the extent of a fortnight. Then, if the blooms are kept cool when almost fully developed, they may be retarded nearly another week, making about eighteen days altogether. There is another advantage in retarding early varieties soon after the buds have been "taken," as the plants are kept in the open air and light reaches every part from bud to base, and this is conducive to a healthy condition of the leaves. Continue the judicious feeding of all varieties of plants in pots, especially those that are intended for exhibition in November.

Plants Trained on Walls.—I have seen old walls beautifully furnished with tall, medium and dwarf-growing varieties, neatly arranged. Some of the early November flowering varieties do very well in the shelter afforded by the walls. At the present time all main branches should be tied in and all surplus side shoots pinched out. The tops of the stems must be left to depend gracefully from the wall; then the clusters of flowers will show to great advantage. Avon.

A CHARMING LITTLE GREENHOUSE CLIMBER.

IN *Manetta bicolor* we have a delightful climbing plant for a small structure, as though free, it is by

no means a strong grower, while the foliage is neat and the bright, tubular-shaped blossoms, in colour red and yellow, are borne throughout the greater part of the year. It is a native of South America, where several other species occur; but though some have at different times been introduced, this is the only one that can be generally obtained from nurseries, and as far as I know it is the best of them all. It is also known as *M. milata* and *M. rubro-lutea*. Apart from its beauty as a greenhouse climber, little examples grown in pots and trained around a few sticks form a very pleasing feature in that structure. Larger specimens treated in the same way are sometimes put out of doors during the summer in the mixed beds of flowering subjects which are now so often seen. Under these conditions they flower continuously, and fully exposed to sun and air the colour of the blossoms is of the richest. Before the craze for size became so universal, a spray of this *Manetta* was often used for the decoration of the button-hole. It can be readily struck from cuttings in the spring, and will thrive in ordinary potting compost. H. P.

NEW DESSERT APPLE MAIDSTONE FAVOURITE. (Five-sixths natural size.) (See page 448.)

used, but where plenty of ordinary ground moss can be obtained, rake it up with an iron-toothed rake, dry it under a glass light, then beat out the dust with the aid of a stick and use it for packing purposes. I have packed many thousands of Peaches in it, and never had one damaged. First, put a thin layer of the moss in the bottom of the box, then place the fruits, each one wrapped in white tissue paper, on the moss with just sufficient space between them to allow of the fingers being inserted. Fill up all such space with moss, and lay enough on the top to permit the lid to be put on, gently pressing down the moss. A number of these boxes, all of similar size, of course, may be tied together securely with strong cord, and they will withstand a railway journey from one end of the country to the other. Melons, Nectarines and choice Pears may all be packed in moss, as the latter is soft, and does not contaminate the fruit with any scent.

Summer Pruning of the Trees.—No time should be lost in completing the work of summer pruning. The earlier pruning would admit more air and light to the ripening fruits, and the branches

sprays of blossoms than single blooms on stiff stems. Earwigs do a lot of harm to the blooms in some seasons. The pests find shelter among the faded, curled leaves near the base of the plant, and the wise cultivator will be careful to remove all such leaves, and with them many earwigs, too. Afterwards, if the buds and opening flowers are examined at nine o'clock each evening with the aid of a lantern, the earwigs left may be greatly lessened and very little harm to the fully-expanded blooms will occur.

Manure-Water in a diluted condition must be freely given to the plants in borders at this season. However good the soil may be, the plants will have robbed it of a great deal of nourishment, and the applications of manure-water are really essential to the full development of the blooms and the deep, healthy colour of the leaves.

Early-Flowering Varieties in Pots.—These are very useful to the amateur cultivator who possesses no glass houses in which later-flowering sorts should be accommodated. The early ones must be well fed, especially if grown in

THE FLOWER GARDEN.

DUTCH CROCUSES.

THROUGH the kindness of two large Dutch firms, who each of them made me a present of a collection of their new varieties, together with a sprinkling of the best of some of the older ones, I had the excitement this last spring of having a small Crocus trial in my own garden. I must go off at a tangent here, just for two or three lines, to advocate such collection-growing as being a most interesting and instructive by-product of the gardening spirit, wherever and wherever circumstances and money allow it to be carried out. It is an exploration into an unknown land, and in a mild way gives us the same sort of expectant wonder as variety after variety unfolds its blooms to our critical eyes. There are lots of things that can be utilised for this purpose—annuals, Sweet Peas, Zonal Pelargoniums, Tulips (both early and late), Daffodils, Hyacinths, Crocuses, Montbretias, and, in fact, almost anything at which seedling raisers and selectors have been at work. One of my "joys," then, this last spring was watching this collection of Crocuses. It was my Mecca for three weeks; I saw it in sunshine and in rain. I looked at it at close quarters and at a distance. I wanted to know which were the best among the whites, the purples, the mauves and the striped. For this purpose I took no account of the dates of opening, nor of the colours matched. I went for those which in themselves appealed to me most. Here is a *réchauffé* of the notes I then made. There were numerous whites, including Kathleen Parlow, which the floral committee of the Royal Horticultural Society somewhat unaccountably gave an award of merit to in the middle of last February, when it must have been grown under glass. It is a magnificent variety, but, "in my foolish opinion," not to be compared to White Lady, whose brilliant anthers out-satironed any that I have ever seen, both in colour and in size. The individual flowers were large, of exquisite shape, of good substance, and freely produced. A real lady in every way. All these large "blowers" are naturally fair-weather sorts. As, however, during part of the trial time we had wet and stormy weather, I found myself very frequently "coming back to" May, a rather dwarf variety with small, ideally-formed, cup-shaped flowers. It has been a great favourite of mine for some time, and if there was not such a rage for size as size, it would probably be the white of commerce.

Among the purples the choice was very large. I find I put the well-known *purpurea grandiflora* equal first with Caesar. This last is a much redder purple than the old variety. Both are very fine

and large flowers, and, except for the difference in the shade of colour, it is almost "six of one and half-a-dozen of the other."

Two other purples that I have down are Hero, a late variety with rich, deep purple, shiny-looking flowers, and Black Knight, the darkest of all in the trials, and, I should imagine, one of the darkest of all Crocuses. It has a fine gloss on the petals, like shirt fronts and collars got up with a smoothing-iron.

The mauves are a small class. The best was Dorothea, a very pleasing shade of lavender, quite distinct from all the others in my collection. It is a long, not particularly large flower, and the corolla is small. I have always found it to be one of the best Crocuses to grow in pots or bowls.

Edna was my "medium"; it is a huge flower with many stripes on a white ground, which are so arranged that the margins of the petals are left without any colouring, giving them a very distinct white edge. Pallas is another very fine large variety, with the three exterior segments almost white and with remarkably showy orange anthers. As the best example of the third I placed Fantasy. It was practically "Hobson's choice." I cannot say I particularly cared for the combination. My notes say: Light and dark purple stripes, edges white, inside of petals pale purple. It was very distinct, undoubtedly, but somehow it was the least pleasing of all my selections.

To sum up, my Crocus trials gave me an immense amount of pleasure and mild excitement at a time when I had nothing else in flower outside.

The different kinds were arranged in solid little blocks of four rows, each with six coriis in a row. Each block was about nine inches from its neighbour, and the whole was arranged in two rows on a long bed in an open place in the garden. JOSEPH JACOB.

THE NEW SCABIOSA CAUCASICA MAGNIFICA. COLOUR, LAVENDER BLUE. (See page 448.)

for this purpose I can strongly recommend it, also May. Second to Dorothea I placed Beauty or Margot—for both names mean the same variety. This is a large Colchicum-looking bloom, with the exterior of the petals a different tone from their interior; the list says, outside pale blue, inside blue. I described it as lavender and heliotrope. Anyhow, it is a grand plant.

The last division is the "striped." The choice was considerable. In the end I decided to pick the best pale, the best medium, and the best dark. Adeline Patti was the one I selected for the first, although I find the list describes it as a white.

C. barbata.—A well-known and very beautiful plant not always easy to grow. It is about a foot high, and has in May and June large, pale blue, drooping flowers on erect stems drooping over at the top. The beauty of the flower is enhanced by the white hairs in the mouths of the blooms. Apt to die after flowering, and should be in dry, well-drained soil or the moraine. Raise from seeds. Sun or shade. The white variety alba is very fine.

C. Barrelieri.—See C. fragilis.

C. Baumgartenii.—This seems only a form of C. rotundifolia.

THE CAMPANULAS OR BELLFLOWERS.

(Continued from page 434.)

C. alpina.—Rather a difficult and short-lived species with some, this is a handsome plant with a spike six inches high, bearing in July large, blue, fringed bells on long footstalks. It makes a rosette of shining leaves. Division is almost impracticable. It is a limestone plant for a sunny place in light soil. It should not be confounded with a pseudo alpina, a handsome variety of C. rotundifolia.

C. Aucherii.—This is a rather new plant of much beauty, resembling C. tridentata in all its parts, but is more vigorous. It has handsome violet flowers in June and July, and should have the moraine in sun.

C. azurea.—See C. rhomboidalis.

C. balchiniana.—A very beautiful plant of the isophylla class, with variegated leaves and soft pale blue flowers in June and July. It is not very hardy, and is a favourite basket plant for the conservatory or window. It can be grown on a wall in the open or in a sunny rockery, but should have a sheet of glass over it in winter. Division or cuttings.

C. barbata.—A well-known and very beautiful plant not always easy to grow. It is about a foot high, and has in May and June large, pale blue, drooping flowers on erect stems drooping over at the top. The beauty of the flower is enhanced by the white hairs in the mouths of the blooms. Apt to die after flowering, and should be in dry, well-drained soil or the moraine. Raise from seeds. Sun or shade. The white variety alba is very fine.

C. Barrelieri.—See C. fragilis.

C. Baumgartenii.—This seems only a form of C. rotundifolia.

C. bavarica.—The name of this plant is a little doubtful, and the one sent for it is known as the Bavarian variety of *C. portenschlagiana*, which see.

C. beauverdiana.—This is a lovely but rare plant, about nine inches high, and giving in June a host of delightfully shaped and coloured starchy flowers. A rather dry rockery or the moraine seems to suit this Caucasian species.

C. bellidifolia.—A handsome Bellflower, about six inches high, with large, funnel-shaped bells, one on the top of each stem, in July. It comes from the Caucasus, and is described in the "Dictionary of Gardening" as *C. Adami*. A rather dry soil in loam, peat and grit, or the moraine.

C. caespitosa.—For all garden purposes *C. caespitosa* and its forms, with *C. pumila* and *C. pusilla*, may be treated as one species. The "Index Kewensis" and the "Kew Hand List" do not seem in entire agreement about this. A study of the forms shows that there is little difference between them, although *C. caespitosa* is certainly smaller and closer in its habit. The white one, known as *C. pumila* or *C. pusilla alba* in gardens, will serve as descriptive of all. The type is blue. Then there is a beautiful light blue one called *pallida*, and Miss Willmott is a charming pale or silvery blue one. *C. tyrolensis* is practically a *C. caespitosa*, and one called *cochlearifolia* is of taller but close growth, and with deep blue flowers. These are easily-cultivated plants almost anywhere, and look well in a wall, moraine, or the crevices of a paved path or rockwork. Easily raised by division or from seeds. Finer in semi-shade than in sun. They flower in June and July.

C. carnica.—A species not much grown, but after the style of *C. rotundifolia*, with narrow flowers, almost tube-like, of a violet purple and about nine inches or ten inches high. Ordinary rock garden soil. June and July.

C. carpatica.—One of the best-known and most valuable of all rock garden or border Campanulas. Some include with this the lovely *C. turbinata*, but there is room for a difference of opinion about this, as the true *turbinata* has more pubescent leaves and rarely more than one flower at the top of each stem. Some also place *C. pelviformis* with *C. carpatica*. There are many varieties besides the type, which is about a foot high, and has open flowers of a pleasing blue. There are such forms as *pallida*, light blue; *alba*, white; *Riverslea* and *Isabel*, handsome flat, blue varieties; *White Star*, large white; *China Cup*, pale blue; *Little Gem*, dwarf blue; *Dickson*, white; and others, besides *C. turbinata* and a white variety of the same nature. All are of easy culture in sun or shade, and are among the latest of the dwarf Bellflowers, coming in July.

(To be continued.)

ROCK AND WATER GARDEN.

CONVOLVULUS MAURITANICUS.

This is often mis-called the Blue Convolvulus, but it is no bluer than some Campanulas and many other mauve and lilac plants that are frequently spoken of as blue. Purplish blue or, better still, bluish purple would more nearly describe the colour. But, any way, it is a lovely plant for a warm, well-drained bank, where it will cover a large space with its constant succession of flowers from June till the frosts come. In some districts it is hard to keep through the winter, but I have had it outside here for many years, fifteen at least, and find that if I get its roots partly under a stone

and whiter. So far its blossoms have been smaller than my older form, but I am hoping that may be altered when it gets more fully established.

Waltham Cross.

E. A. BOWLES.

THE ROSE GARDEN.

WORK AMONG INDOOR ROSES.

ALTHOUGH we are still in the midst of Roses among the open-air plants, it is a very important time with us now among our Roses under glass. With the majority of pot Roses outside, there is much to do among those plants that are turned out into borders or are remaining in large tubs or pots. I have frequently emphasised the importance of a clean commencement in all phases of Rose culture, and it is more than ever advisable when dealing with these plants under glass. Those plants that have had to stay under cover are likely to be carrying a number of semi-ripened leaves that would have fallen in the open by the influence of wind and rain. It often happens that under glass such foliage is simply infested with red spider and thrips. Unless this is guarded against, it stands to reason we are simply harbouring an enormous number of enemies that will play havoc with future growth. I would make a practice of frequently collecting these leaves as they fall and burning them. Do not wait for one final clearing up only. The matured leaves that are affected may as well be cut off and burnt also. They are not of much more service upon the plant, and their absence will facilitate the more complete cleansing of wall, roof, and Rose wood, which I am strongly in favour of at this time of the year, when our houses are the nearest to being empty.

I have often met with mealy bug upon Roses, and scale is quite common. Lessen your foliage as much as the condition of the plants will allow, also the wood; and much may often be cut away now, so that our Roses may be fairly ripened if they are to serve as early forcers. Where possible, and in all cases where many insects abound, I would remove the growth from the supports and thoroughly white-wash or otherwise cleanse behind all Rose growth. Fairly strong measures may be used upon partly-matured wood, and such an opportunity as the present seldom occurs. Look over the borders closely and see that they are uniform. A little well-rotted manure may be forked in, or a dressing of some approved artificial food given. But I would not do much of the latter while Roses are in a dormant state of growth. In fact, clean up and get well prepared for the housing and starting of those plants intended for midwinter flowering, which will soon have to come under cover.

A. P.

CONVOLVULUS MAURITANICUS, A USEFUL PLANT FOR A SUNNY BANK OR ROCK GARDEN.

and leave its own dead leaves and stems on until it begins to shoot from the base in spring, it can be relied upon to rapidly reclothe the space allotted to it. The blossoms open widely in bright sunshine, and are very freely produced. The illustration shows a year old plant in early July, which will cover twice the space before the season ends. It is a native of Northern Africa, and therefore rejoices in hot weather. It is easily propagated by cuttings, but I do not remember ever finding good seed on my plants. I have a deeper-coloured variety here now, with the eye rather more distinct

S. ARNOIT.

SCIENCE IN RELATION TO HORTICULTURE.

"SLEEPING DISEASE" IN TOMATO PLANTS.

THE Tomato disease commonly known as the "sleeping disease" is annually responsible for a good deal of disappointment and loss to market-gardeners. As far as England is concerned, it is a disease of comparatively recent introduction, having first made its appearance in Guernsey, after which it became troublesome in the Isle of Wight and several of the Southern Counties. The grower, as a rule, is given little or no warning of the danger. The leaves of the plant will suddenly droop in a wilted condition and completely lose the power of restoring their rigidity or "freshness," and this stage will then be more or less rapidly followed by the collapse of the stem. It is obviously a case of failure in the supply of water to the foliage. Now, it is well known that the stiffness of a leaf is due to the fact that the tiny cells composing the soft green tissue in the meshes of the network of veins are distended and made firm with water, much in the same way as a pneumatic tyre is made firm by inflating it with air. It is further known that the leaf is constantly losing water in the form of vapour, and that this act (known as transpiration) is absolutely necessary for the promotion of growth. In a healthy plant, however, this continuous loss of water is replaced by fresh supplies taken up by the root system. The absorbed water is conducted through the tubular woody cylinder of the stem, and thence into the veins of the leaf. From the veins the green tissue gets its water to counterbalance the transpiratory loss. In order to keep the leaves fresh and healthy—seeing that transpiration is constant—there must, therefore, be a sufficiency of water in the soil, healthy roots, and unimpeded water-tubes through the stem from root to foliage. The immediate cause of the "sleeping" or wilted condition of a Tomato plant suffering from this particular disease is a blockage in the water-conducting system. If you take one of the diseased plants and cut through the base of the stem, the woody ring of tissue will be seen to be darkly discoloured, and on examination with a microscope it will be discovered that this appearance is due to the presence of densely-packed fungoid threads, choking up the water-conducting tubes. This being so, it is clear that when this stage is reached nothing can save the crop, because it is impossible to scour out these slender, microscopical tubes and clear a passage for the ascending water current. If the plants are so far advanced as to have fully-formed fruits, they may be allowed to colour off, but no further growth is at all possible. If the fruits are still young, the crop may as well be cleared off at once as allowed to remain. But if the present crop

cannot be saved, safeguards can be taken against future loss. There is one thing certain, and that is, if, after the removal of the diseased crop, a second crop be planted in the same soil (unless it is specially treated), the disease will break out again with perhaps increased virulence. This is because infection comes from the soil through the root, and not from the air through the leaves. To understand this we must know something about the life-history of the fungus that chokes up the water-tubes in the vascular cylinder of the stem.

The name by which the fungus is known to science is *Fusarium lycopersici*, and it seems to be able to exist in an organically-manured soil (much as a Mushroom can) as well as in the body of a Tomato plant. In the soil it forms long, slender, thready growths, along which arise swellings that eventually

by such treatment of the soil as will destroy the spores of the *Fusarium*, and thus render it safe for the roots of the young Tomato plants. If the plants are grown under glass, of course one method of treatment might be the entire removal of the infected soil, replacing it with fresh, healthy soil for the next crop, in which case it would be wise (1) to spray the house after the removal of the old soil and before the introduction of the new with a one in twenty solution of carbolic acid, and (2) to take care that the old soil is so isolated that it cannot act as a future source of infection for Tomato plants.

In cases where it is desirable that the old soil should be used, then admixture with a heavy dressing of quicklime has been advocated. But the safest plan is to sterilise the soil by heat. This can only be done in anything like a large scale by

A FINE VARIETY OF THE CARPATHIAN HAIRBELL, *CAMPANULA CARPATICA PELVIFORMIS*.

ripen into resting spores. It has been observed that decayed Tomato stems in soil provide a very favourable food medium for the fungus at this stage of their growth. Infection takes place from the soil, the fungus always apparently selecting the youngest roots. After entering the plant, the fungal hyphae pass into the water-tubes of the woody cylinder and grow up through them into the stem. They branch freely, some of the branches passing to the surface of the lower stem close to the ground, where they form a mouldy covering on the skin. Here, about three weeks after infection, spores are freely produced, which aid in spreading the disease. At first the spores are simple in form, but after about one week's sporulation more complicated spores of a sickle-like shape are formed which are of a pale orange colour, and possess a power of very quick germination. As infection never takes place by way of the stem, but always through the root, it follows that prevention can only be secured

the use of a special sterilising plant, of which several forms are now on the market.

Tomato-growers should also know that it would be extremely unwise to use seeds obtained from parent plants affected with sleeping disease, as it is an admitted fact that such seeds may carry the infection to the next generation. Further, as a matter of precaution, only sturdy plants should be selected for planting, and all shrunken, drawn-up seedlings discarded. Healthy growth should be encouraged by giving a sufficiency of air, light and room during the growing season, while the importance of the addition of lime to the soil, especially if it is rich in organic material, will be obvious to all Tomato-growers.

Royal College of Science for Ireland.

[Messrs. Marshall, Sons and Co., Limited, of Gainsborough, send us particulars of boilers and apparatus that they now let out on hire for sterilising soil.—ED.]

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Gladiolus Lady Faire.—A distinct novelty of remarkable colour. The flowers are white,

NEW GLADIOLUS MRS. BROMET.

lightly marked with a conspicuous chestnut crimson centre.

Gladiolus Lady Northcote. A very pleasing variety, with flowers soft apricot in colour, blended with buff yellow; lip of chrome yellow hue. From the handsome spike that was shown it is obviously a robust variety.

Gladiolus Mrs. Bromet.—The flowers are of a pale creamy yellow colour and borne in a massive spike, as may be seen from the above illustration. These three were shown by Messrs. Kelway and Son, Langport.

Rose Mrs. Andrew Carnegie.—This variety is already well known to exhibitors of Roses. It is the result of a cross between Frau Karl Druschki and Niphetos. A sweetly-scented Rose of grand exhibition form. Described and figured in THE GARDEN, July 20, 1912, page 305, under "Gold Medal Roses."

Scabiosa caucasica magnifica.—A charming and large-flowered variety of this well-known garden plant. The flowers (illustrated on page 445) are deep lavender blue and delightfully frilled at the margin. These two were shown by Messrs. Coaker, Aberdeen.

Montbrelia Queen Adelaide.—Another new seedling Montbrelia that bids fair for popularity. The flowers are over three inches across, well expanded, and of deep orange colour. In the centre of the flower is a conspicuous yellow eye, with a small blotch of red on each segment. Shown by S. Morris, Esq., Earlham Hall, Norwich (gardener, Mr. Henley).

Chrysanthemum Improved Northern Star.—A very pretty annual Chrysanthemum of the C. tricolor section. The ray florets are pure white, with a yellow band at the base surrounding the purple boss or disc in the centre. An idea of the regularity in the marking of the flowers is obtained in the illustration on this page. For garden decoration and cutting purposes it will prove an acquisition. Shown by Messrs. Dobbie and Co.

NEW DAHLIAS.

The following awards to Dahlias were made by a joint committee of the Royal Horticultural Society and the National Dahlia Society. The latter society awarded a first-class certificate, and the former an award of merit, to each variety.

Lily Reed.—A good exhibition variety of the Cactus-flowered type. Colour, lemon yellow. Shown by Mr. Shoesmith.

Aphrodite.—An attractive Peony-flowered variety, white, with orange centre. From Mr. C. Turner.

Tusca.—One of the most striking varieties of the Collarette section we have seen. Crimson, white-centred.

Prince of Orange.—Another Collarette variety. It is self-coloured, of a pleasing orange salmon. These two were shown by Messrs. Dobbie and Co.

Regulus.—A very neat-flowered Pompon of a rich purple red colour. From Messrs. J. Cheal and Sons.

NEW ORCHIDS.

FIRST-CLASS CERTIFICATES.

Brasso-Cat-Lælia The Baroness.—This is a beautiful apricot yellow hybrid, obtained by intercrossing Lælio-Cattleya Ophir and Brasso-Cattleya Mrs. J. Leemann. The flower is a good size, and the lip is prettily fringed. From Baron Bruno Schröder.

Odontonia Eileen.—This is the result of *Miltoma vexillaria* G. D. Owen being crossed with *Odontoglossum Edwardii*. The flower is flat like a *Miltoma*, but in colour, viz., violet purple, it resembles *O. Edwardii*. From J. Gurney Fowler, Esq.

AWARDS OF MERIT.

Lælio-Cattleya Ettrick (*Lælio-Cattleya Bletchleyensis* × *Cattleya aurea*)—A bold flower with rosy mauve sepals and petals, and an almost crimson lip. From Messrs. J. Veitch and Sons, Chelsea.

Lælio-Cattleya Marquise de Wavrin *Orchidhurst* variety.—A purplish magenta hybrid with a dark crimson lip. Exhibited by Messrs. Armstrong and Brown, Tunbridge Wells.

Cattleya hardyana Mrs. Waters Butler (*C. Warscewiczii* × *C. aurea*).—This is a pretty form, somewhat light in colour, but has a large area of yellow in the throat of the labellum. From Waters Butler, Esq., Birmingham.

NEW VEGETABLES AND FRUIT.

Potato Irish King.—A white kidney variety, with clear skin and shallow eyes. From Messrs. Barr and Sons, Covent Garden.

Potato Great Scot.—A white, round variety, with netted skin and rather deep eyes. From Messrs. R. Veitch and Sons, Exeter.

Potato Southern Star.—A white, pebble-shaped Potato, with clear but slightly-netted skin and shallow eyes. From Messrs. J. Veitch and Sons, Chelsea. These had been grown in the Society's gardens at Wisley, having been sent there by the firms named.

Apple Maidstone Favourite.—This is a new early dessert variety of great promise, being a seedling from Emperor Alexander. The fruits are very aromatic, of good size and highly coloured, scarlet, with yellow on the shaded side. A young tree exhibited possessed an excellent, sturdy habit, and this new-comer should prove a very welcome addition to the early dessert Apples, coming as it does just at a time when no other is available. (See illustration on page 444). Shown by Messrs. George Bunyard and Co., Maidstone.

All the foregoing flowers, vegetables and fruit were shown before the Royal Horticultural Society on the 26th ult., when the awards were made.

CHRYSANTHEMUM IMPROVED NORTHERN STAR, A BEAUTIFUL ANNUAL SUITABLE FOR CUTTING.

GARDENING FOR BEGINNERS.

HOW TO GROW VIOLETS FOR WINTER FLOWERING.

THE Violet, though so insignificant to look at, is a flower that finds favour with, I may say, everyone. In sheltered positions outside, the plants bear flowers almost throughout the winter months, but when given the protection of a frame they blossom profusely. Even when ordinarily grown plants are carefully lifted and replanted in prepared beds under glass, they prove very satisfactory; but where the plants have been specially treated through the summer with a view to planting in a frame in September, the results often exceed very sanguine expectations.

Planting in Frames.—Both brick and wooden frames are suitable, but those of medium depth are the best. The Violet loves the light and air, and there is, as a rule, none too much of the former in winter-time. All frames must be duly prepared prior to the lifting of the plants, as when this work is done there should be no delay in getting the lifted plants replanted. If a deep frame—one about three feet six inches or four feet—be used, it will be advisable to put in a hotbed of litter and leaves, but not to allow it to heat violently. If there is a mild bottom-heat for a few weeks, the Violet plants will be benefited. The main object of the hotbed is, however, the raising of the soil so that the leaves of the plants will only be a few inches from the glass when the soil has settled down. If there is plenty of soil and no litter, then the soil may be used. If a shallow frame be used, there will be no need to do more than put in a bed of good compost about a foot deep. Litter beds must be built up to the top of the frame and, in addition, be well trodden down. The litter will naturally sink down, and when the compost is put on, the sinking will be greater still.

Compost.—A good friable loam, if procurable, should form the bulk of the compost. One bushel of sweet leaf-soil to three bushels of loam will be a

THIS IS A GOOD TIME TO LIFT VIOLET PLANTS FROM THE OPEN AND TO PLACE THEM IN FRAMES FOR WINTER FLOWERING.

proper quantity to use. Some sand or road grit must be added. Make the soil firm, and after planting is done keep the surface of the soil loose, but only so with a pointed stick, and do not habitually tread on it between the plants.

Lifting the Plants.—Fig. A shows at No. 1 a grand plant neatly lifted and ready for replanting in the frame; No. 2, a brick frame with a hotbed (No. 3) made in it; No. 4, the bed of compost with the plants duly put in. No. 5 depicts a wooden frame with a deep bed of compost (No. 6) in it. Here the plants (No. 7)

are close to the glass. It is easy to admit abundance of air by tilting the lights on the opposite side to that on which the wind blows. A south aspect is the best, and it is improved if there is a low fence or other protection on the north and east sides.

Protecting Plants in Open Borders.—All cultivators are not able to afford frame room for their plants, but nearly all can give them some protection, which greatly assists the flowering capacity of the plants. Fig. B shows at No. 1 stakes driven into the ground a few feet from a low wall. Glass lights are placed on the cross sticks (No. 2) and protect the Violets growing in a prepared bed (No. 3). Even a border similar to No. 4 would be useful. The lifted plants and those growing permanently in beds, as shown at No. 5, must be relieved of all runners (No. 6). Another simple way of protecting the plants in beds is shown at No. 7. Iron hoops or Hazel sticks should be fixed over the bed of plants, as shown at No. 8, and mats (No. 9) placed on them in bad weather. No. 10 shows bucks or blocks of wood to keep down the mats. Fully ventilate all plants in fine weather.

WHEN FRAMES ARE NOT AT COMMAND, VIOLETS MAY BE GROWN IN THE OPEN BORDER AND PROTECTED AS DEPICTED HERE.

CUCUMBERS IN COOL FRAMES.

THE summer has not been an ideal one for the successful cultivation of Cucumbers in frames. At the same time it is not economical to attempt to renovate hot-beds where the plants now possess, mainly, yellow leaves and stunted fruits. Such should be cleared out without delay. Where the plants are younger, however, the cultivator may greatly assist them to bear well until the end of September, or even to the middle of October, if he cuts away all old material from the bed outside the frame and replaces it with fresh, littersy manure; the heat will permeate the whole bed.

SHAMROCK.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Bulb-Planting.—Although full early yet for the planting of bulbs in beds and borders, there is no reason why Scillas, Crocuses and Narcissi should not be planted where they are to be naturalised in grass. When planting under trees, on banks, or on the outskirts of woods for natural effect, the bulbs must not be planted in an orthodox manner or the clumps be of one size or contour, but should be irregular masses that are fairly thick in the centre, gradually thinning out towards the outer edges till they merge almost imperceptibly into the surroundings. Too thin planting can never be effective, for it is a bold mass of colour that strikes one at a fair distance away which is the most effective. Those varieties that are small in stature, or that are grown for the novelty or shape of the blooms, such as *N. cyclaminus* and *N. Bulbocodium*, are far better planted in small clumps on or near the rockery, where they can be examined without too much stooping.

The Rock Garden.

General Work.—Just now there is not much bloom in the rock garden, and the very dry summer has tended somewhat to shorten the season of flowering. To keep many subjects alive, much artificial watering has had to be done, but even with this many of the subjects have suffered considerably, and to keep the rockery even tidy in appearance a great deal of picking over is necessary. As mentioned under the heading of pleasure grounds, bulb-planting may be done now, and many species and varieties of Tulips, Narcissi, Snowdrops, Scillas, Fritillarias, Muscari and Irises may be planted to give a very pleasing effect during the early spring months. Where the natural soil of the rock garden is very heavy, it may be an advantage to lighten the soil somewhat with leaf-soil and a little sand. It is also wise to mark where each clump of bulbs is, so that when planting other subjects they may be chosen so as not to clash with or cover the bulbs too densely, or the effect may be spoiled.

Plants Under Glass.

Pot Roses.—Where these are cultivated for early spring forcing, the present is a very good time to go through them, potting those that require it and top-dressing others. A fairly holding and rich loam is best for Roses, with a little bone-meal added to it. After potting, to encourage root action, the pots should be placed fairly closely together, or they may be partially plunged in ashes, or old litter placed between them will answer the same purpose. Precautions should be taken against worms getting into the pots, or they will prove troublesome when the pots are taken indoors. Spray lightly overhead for a few days after potting, should the weather be hot, not forgetting the necessity of keeping down mildew by using one or other of the fungicides.

Climbing Roses, such as *Crimson Rambler*, *Dorothy Perkins* and *Hiawatha*, should be potted every season, as these make much more root than the *Hybrid Perpetuals* and *Hybrid Teas*, though, unless very large plants are required, the balls of soil may be reduced somewhat at the time of potting, so that they may be returned into pots of from 9 inches to 12 inches in diameter.

Cannas.—Where these are grown under names or numbers, they should be gone over before they go out of flower to see that they are correctly named, as even one or two wrongly named this season may mean a fairly general mix up next year after the plants are split up. This remark applies equally well to any collection of named plants.

Primulas.—The latest batches will now be ready for their flowering pots, and there is no advantage in giving too big a shift at this season. Rather lighter soil may be used now as an inducement to quick rooting, and if the plants are at all backward, a little warmth in the frames or house during the night will help them materially. Earlier batches should be given more space as they require it, so that they may develop good, strong and healthy foliage that will keep through the winter.

The Kitchen Garden.

Winter Brassicas. In this neighbourhood, owing to the drought, many of the early-planted

Brassicas have not done as well as one would like to see them, and it may be wise, even at this late date, to plant as many Christmas Cabbages, Coleworts and Kales as can be got, so as to make up any deficiency. It is not necessary to plant these very far apart; 18 inches between the rows and a foot apart in the rows should be ample.

Cucumbers for winter use must be planted at once, so that they may become nicely established before the really short days. The temperature at night must be kept up fairly well to maintain a steady and healthy growth, and the syringings must not be so heavy as earlier in the season. Sufficient moisture must be given to ensure them being kept free from spider and thrip. Plants that may be fruiting in frames may be kept going some little time longer by giving the frames a good lining of fresh manure and, if necessary, a top-dressing of soil or manure inside the frames.

Fruits Under Glass.

Pot Trees.—Early-forced Peaches and Nectarines should be repotted before they lose their foliage; hence the matter should be taken in hand at once, doing the earliest varieties first and following on with the others as they become fit. Turfy loam, lime rubble, wood-ashes and a little bone-meal make a suitable compost. Except in the case of very young trees (which may be given a size larger pot), most of the trees will have to be returned to the same-sized pot, so that the old ball of soil must be considerably reduced. This should be done carefully with a pointed stick, cutting back all the large roots and preserving the fine ones as much as possible.

Careful Crocking is very necessary, and it is best to err on the side of overcrocking rather than under, as once the soil becomes water-logged the fruit is bound to suffer; so cover the crocks carefully with good fibre before adding fresh soil, ramming this latter very evenly all round, leaving sufficient space, wherever possible, for a top-dressing or two during the growing season. After potting, water thoroughly and keep well syringed for a few days until the leaves show signs of firmness again, when the syringing may gradually be left off. Plum trees also should be potted as they become fit, the same details applying here as to the Peaches and Nectarines.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Dahlia.—These showy autumn flowers are now at their best. The plants should be carefully gone over, and any shoots that are likely to be damaged by the September winds should be looped loosely in with binder twine. See that all the plants are correctly and legibly named, as it is much easier to identify doubtful varieties now than later on.

Gladioli.—See that none of the plants gets "hanked" on account of growth being made below the tie. Cut away any decayed flowers. I can strongly recommend *America* as a vigorous flesh-coloured variety for growing in quantity.

Carnation Layers.—These should mostly be rooted now, and, if so, should be severed from the parent plant and either planted where they are to bloom next season or planted thickly where they can have the protection later on of some sashes. We pot them up, but where there are large quantities grown, this is not always practicable. Spring planting is to be commended on clayey subsoils such as we have to deal with here.

Chrysanthemums.—These are now turning in, and will form one of the chief sources of the cut flower supply for some time. See that stakes and ties are all right, or much damage may be done by the autumn winds which are sure to come.

Sweet Peas are now getting past their best, but should stand out till the end of the month if the weather is fine. A dressing of soot or other stimulant will help to keep the flower-stems from shortening too rapidly.

The Rose Garden.

Mildew.—If present, this ubiquitous fungus must still be fought. Sulphide of potassium, at

the rate of half an ounce to a gallon of water, is the most popular mixture for spraying with.

Preparing for Planting.—In two months hence the planting season will be on, and where planting is proposed and the ground is available, the preparation of the soil should be proceeded with as soon as possible. No plant appreciates the benefit of deep cultivation more than the Rose, and the ground should be trenched not less than 2 feet deep. A fairly heavy soil is preferable to a light one, and whatever the nature of the soil, happy are those who can incorporate some maiden loam with it. A dressing of lime and wood-ashes will also prove beneficial. For the benefit of beginners I hope to say something about varieties next week.

The Shrubbery.

Rhus Coriaria.—This is a most desirable subject for the shrubbery, as its purplish red foliage is very telling in autumn.

Planting Rhododendrons.—Those who contemplate planting Rhododendrons will not find a better time for the operation than the month of October. It will be well to get the soil ready for them now. Although peat is the ideal medium for Rhododendrons to root in, yet for most of the popular varieties peat is not essential, although a proportion of it is desirable. Silky loam and sand mixed with peat, moss litter from the stables, or half-decayed Oak or Beech leaves will grow Rhododendrons quite well. Beginners should note that these plants hate lime in every form.

Plants Under Glass.

Housing.—This work must now be proceeded with, beginning with such subjects as *Azalea indica*, *Camellias* and *Salvia splendens*. The pots should first be thoroughly washed, and any greasy substance cleaned off the surface of the soil with a thin piece of wood. Any plants requiring top-dressing should also have attention. Any necessary staking or tying should also be done now.

Potting Bulbs.—A first batch of bulbs should now be potted up if early bloom is wanted. Hyacinths, Tulips and Narcissi are all the better for being plunged in ashes, sand, or light soil for about six weeks after being potted or boxed. Give a good watering after potting or boxing.

Framing Sweet Violets.—This work should be taken in hand now. See that all runners are cut away before lifting the plants. Lift with good balls of soil, and plant in frames near the glass in about a foot of rich loamy soil. Water well when finished and put on the sashes, but keep them well tilted up night and day for the present. Shade may be afforded in the middle of the day for a week if bright sunshine occurs.

The Hardy Fruit Garden.

Manuring Small Fruit Trees.—Most authorities are now agreed that Gooseberries and Currants, especially those which have borne heavy crops of fruit, are benefited by an autumn dressing of some readily assimilated manure, natural or artificial; this assists the plumping up of the buds, in which much of the energy necessary for next season's work is stored.

Pinching.—This is a good time to go over the Apple and Pear trees and pinch the growths back to about three inches of their bases. If this was done earlier, the trees are apt to make fresh growth, but done at this period it assists the process of energising the buds.

The Kitchen Garden.

Storing Onions.—Bulbs which have been pulled for some time should now be bunched and hung up in an open shed. The remainder of the crop had better be lifted now, but if any portion of it refuses to go to rest, bend the tops gently over to arrest growth.

Planting Spring Cabbages.—This work should now be carried out. The small varieties used for this purpose may be planted thickly, 15 inches by 12 inches being quite wide enough. If pigeons are about, it will be well to put up a scarecrow.

Hoing.—Run the hoe in between the rows of recently-sown Onions and Spinach, and all vacant ground should be kept clean and tidy.

Spring Lettuces which were sown last month will now be ready for transplanting, and the warmest part of a south border should be selected for the crop.

CHARLES COMFORT,
Broomfield Gardens, Davidson's Mans, Midlothian.

A CUNNING HAND AMONG THE BRANCHES.

THE following notes on the bifurcation and branching of trees, copied from *Chambers' Journal*, Vol. VII., January to June, 1857, have been sent us by a reader: "Did you ever notice that sometimes two branches of a tree produce a perfect bifurcation; that is, that they separate from a common point? If you examine closely, you will find that such branches took their departure from one and the same bud. In rarer instances, you may see five or six branches all starting from a common centre, and with a regularity that surprises when contrasted with the arrangement of the rest of the tree. These effects are now and then produced by gemming or inoculating, and not seldom by the unassisted handiwork of Nature. When the latter is the case, the bifurcation is caused by the bite of a caterpillar or some other voracious insect. An insect has but to gnaw the point of a bud to make it grow double, triple, quadruple and so forth, to transform itself, indeed, into numerous buds, thereafter distinct and separate, each passing singly through all the phases of its vegetation. What is here said applies to buds that produce wood; it is equally true of those that produce fruit. The insect plies its mandibles and quite unconsciously starts a new order of developments. After all, however, a little reflection would lead us to believe that buds might be as fecund as seeds. If one grain of Wheat produces many grains, why not one bud many buds, if we can only get it into the right condition? What this condition is we learn from the insect. At all events, it has been learned by M. Millot-Brulé of Réthel (Ardennes), and turned to good account, for he produces effects at pleasure without waiting for the accident of an insect: With the point of a penknife or a slip of sand-paper he makes buds produce as many branches as he chooses. The notion occurred to him in 1849, and he at once made experiments which were successful; and, repeating these year by year, he has now produced a new and similarly interesting process of arboriculture. A Commission appointed by the Minister of Agriculture and Public Works to examine into it reported in the following terms of what they had seen in M. Millot-Brulé's gardens: Several Peach stems present a multitude of branches proceeding from the same centre with mathematical regularity and symmetry. By skilful disbudbing, by incisions, and nipping of the buds or shoots he arranges the trees in a way at once the most picturesque and fantastique. Under his fingers the obedient branches assume the most varied and elegant forms: he increases the fructification, and develops the formation of buds according to his wish. Thoroughly to illustrate the results, diagrams would be necessary. We shall, however, endeavour to explain as clearly as the subject will admit of. M. Millot-Brulé's elementary figure consists of a straight branch which from one common centre separates into fifteen branches, resembling, in fact, a small tree with a regularly formed head. A second represents an espalier Peach tree, the branches of which radiate in the form of a wheel, each branch terminating in an oval ring of smaller branches, developed at regular intervals. From these simple forms others of a more complex nature may be produced: a single stem, properly managed, will form a square, a parallelogram, or a series of

circles so elegant in design that if copied in papier-mâché they would be prized as graceful ornaments for the drawing-room. The buds may be multiplied and the branches sent off entirely at the pleasure of the cultivator. Hence there is no limit to the forms which may be produced. In the course of his experiments he discovered one of the interesting secrets of arboriculture—namely, that little branches must not be developed immediately opposite each other on a horizontal branch trained against a wall, or on stakes; and the reason is, that the branches which run upwards take up all the sap at the expense of those running downwards; the latter, consequently, languish. It therefore becomes absolutely necessary to develop the small branches alternately—each lower one between two upper ones—on all horizontal branches. It is possible, moreover, to assist the lower branches by bending the upper ones upon themselves, making them form a sort of knot, but always with the precaution of leaving the extreme points in an upward direction.

"The process in its simplest form appears to be to decapitate the buds with a penknife as soon as the sap begins to circulate in the spring. In a few days two new buds appear at the base of the bud thus operated on, and the vegetation of these is easily equalised by expert trimming, or pinching off when necessary. The equilibrium once established, these two buds may be similarly treated, and as each will produce two more, any number of branches may be obtained, and a thick, full head developed on the top of a single stem. To make branches shoot in different directions, the terminal bud of the main branch is pinched at one side or the other, according as the direction required is to the right or left; and the new buds being pinched in turn, perfect control is established over each branch from its very earliest growth."

ARSENIC COMPOUNDS AS INSECTICIDES.

VARIOUS compounds of arsenic are used in gardens as insecticides, and quite a number of the proprietary preparations sold for a similar purpose have that substance as one of the active ingredients. All these preparations are deadly poisons, hence they must be used most carefully and judiciously; where they are employed on fruit trees and bushes or on plants which will be taken to the kitchen, the subjects treated should always be syringed strongly with tepid water the next day, and even then spraying should cease at least a fortnight before the products are to be used. When the plants are not edible, nothing can excel arsenic as a thorough, long-lasting insecticide, and there should not be the slightest hesitation in using it freely. A little experimenting may be done to see if the plants are not injured by the mixtures which the gardener expects to spray in the garden, and this will prevent damage being done by scorching of the foliage; otherwise half-hardy and hardy vegetation of all kinds will not be affected in the least. We have never used any of the substances we are about to mention on decorative stove plants; perhaps the Editor may allow a little correspondence from those who have. [Certainly.—Ed.] During early summer Rose caterpillars and chafers, Gooseberry caterpillars and all foliage-eating pests will be

unknown where an effective arsenic preparation is employed.

Paris Green is the substance most commonly in use. It is insoluble in water and apt to scorch plants when used too strongly. The presence of lime prevents the scorching effect, and at the same time holds the particles longer in suspension in the water or liquid. A useful strength at which this substance can be used is 1oz. in five to ten gallons of lime-water—surely a cheap preparation when the Paris green can be had for 2d. an ounce. Stir the Paris green into some water until a thin, creamy liquid is obtained; pour this into the requisite gallons of lime-water, stir well up and keep stirring all the time during spraying; the substance clings fairly well to the foliage; the mixture keeps indefinitely. Spray in the evening or on a dull day when there is no strong sun, and see that the under sides of the foliage get attention. No great force is necessary, but the finer the spray the better film will be obtained over all the plants.

Lead Arsenate is more difficult to work into a thin homogeneous liquid, but once a fine mixture is obtained it lingers much longer in suspension, and stirring is not absolutely necessary if the mixture is used shortly after it is prepared. This substance is much more adhesive and will remain on the foliage even after very heavy rains; it is better than Paris green in wet weather. The action of the lead compound is slower than the former, but where the preparation is utilised to prevent an attack, rather than to eradicate a virulent pest, it will be found preferable. Many experiments have been carried out lately with

Arsenate of Iron, and these seem to prove that this is even more efficient and desirable than any of the others. Each of the three is made as recommended for the first. Iron arsenate adheres well to the foliage, and has the merit of proclaiming its presence by the dirty green film or skin over all the subject which is sprayed. This preparation is advised for Vines, and, as it does not have the scorching effect of Paris green, should be made use of when delicate plants are under treatment. After fruits are removed from plants or bushes which have been attacked by caterpillars or other pests, they should be sprayed with the arsenic mixture immediately; even in mild attacks or as a preventive its use is justified. Birds will leave buds or flowers severely alone if arsenic has been used, and practically all summer pests, including slugs, are non-existent when it is freely sprayed over the plants.

All the compounds mentioned are cheap and, in small quantities, about equal in price. A 1lb. tin of the dry powder or paste will serve a long time, and for cheapness, combined with efficiency, cannot be surpassed. H. H. A.

THE EDITOR'S TABLE.

A Tall Gladiolus.—Messrs. Barr and Sons of King Street, Covent Garden, send a Gladiolus plant, the flower-spike of which attains a height of 8 feet. Messrs. Barr write: "We thought you would like to see a specimen of a wonderfully tall new Gladiolus called Semaphore. It is a hybrid *gandavensis*, and has been grown for us in the trial grounds of the National Gladiolus Society at Locksheath, Southampton. All the plants reached a height of 6 feet, but this, you will see, is still taller. At Locksheath it towered above all other varieties."

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

STOCKS DYING (M. T.). We failed to find any insect or fungus to account for the death of the Stocks, and the only thing to be noticed (apart from the brown and yellow colouring they showed) was the poor development of the root, as though wireworms or some other soil pest, which, however, was not present in the specimens, had destroyed them.

LILY DISEASE (R. T.).—The white Lilies are attacked by the ordinary Lily disease, due to the fungus *Botrytis cinerea*. The only thing we can suggest is to see there is plenty of lime rubble in the soil, that the plants are protected from cold winds, and to remove the top 2 inches or 3 inches of soil in spring and replace it with fresh sterilised soil. It must, however, be confessed that these measures are not entirely successful. The *Lilium auratum* are attacked by the fungus *Rhizopsis* in the bulbs, and as no cure is known, it would be well to destroy them.

HONEYSUCKLE AND ROSE (Miss E. B.).—There does not appear to be any reason why your Honeysuckle and Rose should not flower under the conditions you name, unless you have over-pruned them. The Honeysuckle may be left quite unpruned this and next year, when you will probably obtain flowers. As a rule, Honeysuckles do not flower so well when young as they do later. Try removing the weak shoots from your Rose and leaving the more vigorous ones unpruned. It may then blossom next year. The positions are not likely to be at fault.

ABOUT NARCISSI, LILACS AND ZONAL PELARGONIUMS (H. S.).—You may take up the Narcissus bulbs and replant them at once. The lifting of the bulbs soon after the flowers had faded would give them a greater check than lifting them now. In pruning standard Lilacs, it is only necessary to remove very weakly shoots that would cause overcrowding as soon as the flowers have faded. Newly-potted Zonal Pelargoniums will lose leaves if the soil is kept too dry or over-watered. The leaves first turn yellow and then fall off. These plants may be repotted at any time of the year, except in the depth of winter, when the artificial heat is low. Probably your Lemon-scented Verbena plant had got dry at the roots. When this condition obtains, the leaves soon become spotted and shrivel up.

TREES AND SHRUBS.

CLEMATIS FAILING (Decon).—We regret to hear that Clematis Vitalba will not grow in your neighbourhood, and suggest the following climbers for trial: *Lonicera opuncata* var. *halleana*, *Celastrus articulatus* and *A. tomentosus*. All are vigorous growers, and it is probable that they will prove successful with you.

DWARF EVERGREENS FOR A DRY BANK FACING SOUTH (A. B.).—The following shrubs are all suitable for your purpose: *Vincetoxicum*, 3 inches to 4 inches, flowers blue; *Hypericum calycinum*, 9 inches to 12 inches, flowers yellow; *Helianthemum vulgare* and varieties, 6 inches to 9 inches, flowers yellow, red, rose and white; *Cistus monspeliensis* and *C. corbariensis*, 12 inches to 18 inches, flowers white; and *Juniperus Sabina prostrata*, 6 inches. Any or all of these plants are likely to thrive and provide a good effect.

LARCH LEAVES FOR EXAMINATION (M. T.).—The Larch is attacked by the insect called *Chermes Laticornis*. It is a nearly all of the aphides or green flies; but the waxy threads which proceed from its body prevent the insecticides from reaching it quite as easily as they will the ordinary green flies. Another thing complicates its history, in that in autumn, from now onwards, the *Chermes* leaves the Larch and goes to the Spruce, on which it passes the winter, the insect there producing curious, rather cone-like galls. The best treatment will be to spray the trees with a nicotine wash now, so as to kill as many of the insects as possible.

THE LARGEST TULIP TREES (H. R.). Two of the largest specimens of the Tulip Tree (*Liriodendron tulipifera*) growing in the British Isles are to be found in the respective gardens of Sir E. Loder at Leonard-lee, Horsham, Sussex, and Miss Talbot, Margam Park, Port Talbot, South Wales. These are between 95 feet and 105 feet high, with very large trunks. We have no evidence as

to where and when the first variegated-leaved variety appeared. A great deal of information respecting large trees of this species may be obtained in "Trees of Great Britain and Ireland," by Messrs. Elwes and Henry.

TREATING A BANK (M. D.).—We think you have in the plants you name—*Rhododendron*, *Azalea*, *Buddleia* and *Veronica*—a capital set, and as in each case these are to be had in considerable variety, we should feel inclined to make the most of them. Double *Gorse* and some of the hardy *Heaths*, varieties of *Erica vulgaris* more particularly, might also be added, the latter being planted in irregular groups or masses along the lower portion of the bank. The bank would of necessity require some preparation, digging and manuring, and the former might be done liberally. The *Buddleias* might be planted at intervals of a dozen feet along the upper part, with groups of the Portuguese *Heath* intervening; then might appear *Veronicas* and *Rhododendrons* in the order named, or, if more variety was desired, the yellow-flowered *Porsythia* could be introduced here and there.

THE GREENHOUSE.

PERPETUAL-FLOWERING CARNATIONS (J. E.).—These may be grown on a second year, but, of course, a great deal depends upon the condition the plants are in. Furthermore, some varieties lend themselves to this treatment much more readily than others. As you speak of your plants being very tall, and, presumably, poorly furnished at the base, we should say that they are, in all probability, not worth persevering with for another season.

WATER TANK IN GREENHOUSE (M. E. G.).—Undoubtedly the large tank would be very useful in the greenhouse, and the water in it would be very nearly as warm as the temperature of the structure. You may cover the top of the tank with boards, having a small linged door in a convenient place for the withdrawal of water as desired. There would be no excessive moisture from the covered tank—none that would prove harmful to plants in the house.

ARUM MRS. ROOSEVELT GOING WRONG (Hints).—Too much water is the main cause of your plants of Arum Mrs. Roosevelt behaving as they have done. Of course, we know nothing of the condition of the bulbs when potted, but standing in saucers of water would account for your non-success. In potting the bulbs, the pots should be effectively drained, and the soil watered but moderately till growth appears. Then, as leaves and flower-spikes develop and the pots get well furnished with roots, copious supplies of water should be given, but at the same time facilities must be allowed for the surplus moisture to drain away. After flowering, the pots may be stood out in the open till the leaves die down, when they must be kept dry in the greenhouse during the winter, and in early spring shaken quite clear of the old soil and be repotted.

PRIMULA OBCONICA (J. E.).—Presumably your *Primulas* have been flowering for some time, and are now past their best. If in good condition, they are certainly worth keeping, providing you give them careful attention with as little delay as possible. We should advise you to cut off all flowers and flower-spikes and any old and exhausted leaves; then turn the plants out of their pots and remove as much of the old soil as can be done without unduly distressing the roots. After this, repot in a mixture of loam, leaf-mould and sand, and place the plants, if possible, in a frame where they are shaded from the direct rays of the sun. In most cases you will doubtless find that after the superfluous soil is removed, the plants will not require pots any larger than those in which they have been grown. After repotting, the roots will soon take possession of the new soil and fresh blossoms be quickly pushed up.

BLUE AND MAUVE FLOWERS (H. S.).—In our opinion you are set an impossible task, for the number of blue and mauve flowers suitable for such a purpose is very limited. Even if flowers of all colours were allowed, and you have only a vinery and forcing pit in which to grow them, it would be a difficult matter to keep up a succession all the year round. By eliminating all flowers except those that are blue and mauve in colour, you are deprived of most subjects generally used for decorative purposes. *Hyanthus*, *Crocuses* and *Setilla sibirica*, if potted soon, may, by forcing, be had in bloom early in the year, and *Negesia Blue Gem*, sown in the autumn, will flower in the spring. *Cinerarias*, too, may be had in various shades of blue, and *Primulas* also will supply the required tints. In summer you may depend upon such subjects as *Campanulas*, *Achimenes*, *Gloxinias*, *Statice* of sorts, *Sollya Drummondii* (the Blue-bell Creeper of Australia), *Solanum Wendlandii*, *Streptocarpus*, *Exacum macranthum*, *Imbricatus Olivieri* and *Plumbago capensis*. In late summer the rich purple-blue flowers of *Lasiandra macrantha* are very showy, but in late autumn and winter the choice is very limited. Colours throughout, a beautiful rich blue flower, is very fine at that season, but it is delicate for room decoration, while two mauves are *Erlanga tomentosa* and *Erica melanthera*.

FERNS FROM SPORES (Hints).—The spores should germinate in about a month. The first sign of growth is a green moss-like substance, which covers the surface of the soil. The spores of most Ferns are so minute that it is almost impossible to sow them thinly; hence close inspection of the moss-like matter will reveal the fact that it is made up of a vast number of tiny scales. As these grow crowded together, they are very liable to damp off, to prevent which small clumps must be carefully lifted and pricked off into prepared pots or pans of fine soil. A small-pointed stick will be very useful for lifting them from the seed-pots and also for pricking them off. It is, of course, necessary to keep them shaded.

Directly the young fronds commence to push up, they should be again pricked off, in order to allow space for their development. In some soils a tiny moss will make its appearance quite as soon as the germinating spores, and will choke many of them. To prevent this it is a good plan to bake the soil before the spores are sown on it, as this destroys both vegetable and insect pests.

ROSE GARDEN.

SIZE OF SHOW BOX (Ayrshire).—For twelve blooms the box must be 2 feet long, and all boxes are 18 inches wide and 4 inches high in front. The tubes must be 5 inches apart each way, measuring from the centre of the tube.

WICHURAIANA ROSES TO DROOP OVER WALL (Braemar).—*Wichuriana* would do well, but *Leuchtstern* would be too stiff in growth. Other good, bright kinds would be *Excelsa*, *Sodoma*, *Newport Fairy* and *Troubadour*, and the following, although not reds, would be excellent: *Shower of Gold*, *Fran C. Husse*, *Leontine Gervaise*, *American Pillar* and *Silver Moon*.

ROSES FOR COLD GREENHOUSE (E. Langman).—You would find "The Century Book of Gardening" very helpful to you, as it gives abundant hints in greenhouse management. It is published at these offices. "Rose Growing Made Easy," also from the same offices, gives most useful hints on the greenhouse culture of Roses. You could grow excellent Roses on the walls marked A and B. We advise some climbers on A, such as *Gustave Regis*, *Florence II*, *Veitch*, *Mme. Abel Chateaufort*, *Billiard et Barre*, *Climbing Lady Ashtown*, *Climbing Mrs. W. J. Grant*, *Climbing Liberty*, *Climbing Richmond*, *Bouquet d'Or*, *Caroline Testout* and *Fran Karl Druschki*; for Wall B, *Mrs. H. Stevens*, *General Marabout*, *Lyon Rose*, *Mme. Ravary*, *Duchess of Wellington*, *Mrs. Amy Hammond*, *Sunburst*, *Joseph Hill*, *Prince de Bulgarie*, *Mme. Charles Lutand* and *Edward Mawley*. Prepare the border well, digging it 3 feet deep, and add some good manure and basic slag to the lower soil. Plant in October or November, and prune back hard the first season about February.

KITCHEN GARDEN.

PARSLEY TURNING PINK (C. G.).—You might, perhaps, try the effect of watering the Parsley with a weak solution of sulphate of potash (half an ounce to a gallon of water). It may be owing to lack of potash that the plants are losing their green colouring.

ASPARAGUS THREE OR FOUR YEARS OLD (Miles).—The bed should be in full bearing next year. Cut all the young grass next season which appears above ground until June 20. Then stop cutting for good for that season. The small grass, if cut young, is excellent for samps. For the summer treatment, keep the bed free from weeds; give a good soaking of manure-water from stable or cowyard in July, repeating the dose a month later and again about the middle of September. If manure-water is not available, the following will answer the purpose as well: To every two gallons of clean water apply a good handful of best Canary Guano, well dissolving it in the water before applying. For the autumn and winter treatment, as soon as the grass is ripe and yellow, cut off and clear it away immediately afterwards, and rake off the loose soil or spent manure into the alley or path beside the bed. Then cover the bed over with half-rotted farmyard manure, spreading a little soil from the alley to give the bed a neat appearance, turning over the surface soil of the alleys at the same time to give them a tidy appearance during winter. For the spring treatment, at the end of March rake off the loose part of the top-dressing (manure placed on in autumn) into the alley, then dig the alley up by the side of the bed (on both sides), mixing the manure, and well water the soil. Having done this, cover the bed over (4 inches deep) with the soil from the alley. The young grass will be partly blanched in this soil as it grows, and should be cut close to the crown of the plant with a proper Asparagus knife as soon as it is 2 inches or 3 inches above ground. The best time to apply salt is immediately after the bed has been covered with soil in spring. It should be applied at the rate of a pint to the square yard of ground.

MISCELLANEOUS.

THE BEST BLACKBERRY (Patch).—We think the best is the Parsley-leaved English Blackberry. We know of a plant growing on woodland with at least 30lb. of fruit on it, the first lot of fruit being picked a week ago. This is an old and well-known variety, and any nurseryman advertising in THE GARDEN will supply you.

MUSSEL SCALE ON PEARS (H. J. H.).—The Pears are badly attacked by the mussel scale. Spraying with caustic soda (2lb. to ten gallons of water) while the trees are dormant is the best winter treatment, for it loosens and causes to fall many of the scales made by the female under which to deposit her eggs. Scrubbing is a good measure on the trunk. If this treatment is insufficient (as is likely when the attack is so very bad), spray again when the young scales hatch out in June (or sometimes in May) with a nicotine wash.

COX'S ORANGE APPLE TREE (K. M. K.).—The blossom with which the tree is now furnished is the result of the premature opening of a few of the fruit buds, which not infrequently happens on trees recently planted or trees which have been root-pruned. The resulting fruit, if any, will be of no use, so the blossom had better be picked off. It should make little or no difference to the tree fruiting all right next year. Give the soil a good liming this autumn, forking it into the soil 4 inches deep, and applying it at the rate of one gallon to the square yard.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographs in charge of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Musk Without Scent. Will F. M. Smithey, whose note on the above subject appeared on page 430 of August's issue, please send us his full name and address. We have a number of letters to forward to him.

Collarette Dahlia H. Farman.—This is one of the most showy members of a comparatively new race, and a valuable plant for the outdoor garden just now. Its flowers stand well above the foliage, and their crimson scarlet and deep primrose colour is very striking. Although not greatly enamoured with Collarette Dahlias, we cannot overlook the usefulness of the variety under notice where bold masses of colour are desired.

The Early-flowering Cosmos.—For some weeks we have been enjoying the dainty blossoms of the early-flowering Cosmos, a race introduced some few years ago by Messrs. Dobbin and Co. We have three varieties, viz., Crimson King, Rose Queen and White Queen. The drawback to the old Cosmos bipinnatus was its late flowering, but this has been entirely overcome in this new race, the units of which deserve to be grown in every garden. They are very dainty for cutting.

The Purple Cone-flower.—One of the most attractive plants in the herbaceous border just now is the Purple Cone-flower, *Rudbeckia atripurpurea*. This is a hardy perennial of stately mien, attaining a height of 5 feet or more in good soil. The flowers, which resemble in shape those of a perennial Sunflower, are bright rose purple in colour, and the plant is sometimes erroneously referred to as the red or purple Sunflower. It seems to appreciate well-enriched soil and a fairly open position.

A Beautiful Herbaceous Lobelia.—One often sees and reads of the red shades of Lobelias of the tulgens and cardinalis type, but seldom is any mention made of the beautiful Lobelia Milleri, with its flowers of rich purple. It is a hybrid between the well-known *L. fulgens* and the hardy *L. sylvatica*, and is quite as easy to grow as any of the others. A large bed of any of the ordinary bedding yellow *Calceolarias* intermixed with this little-known Lobelia makes a very effective autumn combination.

Fuchsias for the Outdoor Garden.—Anyone desirous of growing ornamental free-flowering plants with little trouble would do well to try some of the hardy Fuchsias for the wild garden, the front of shrubberies, or in a large bed by themselves. They commence to flower in June or early in July, and give a wealth of blossom from then until the frost comes. There are several kinds, but *Fuchsia gracilis* is perhaps the better known, although *F. globosa*, *F. Riccartonii* and *F. coccinea* are equally as good. In the South-West and other more favourable parts of England they form hedges, but in the colder regions of this country they are best

treated as herbaceous plants, cutting them down in winter. If the weather is very severe they should have a layer of ashes put over the crowns; but it must be taken off as soon as the weather breaks. They may be increased by cuttings now, or by divisions in the spring.

The Lyre-flower as a Pot Plant.—The beautiful *Diocentia spectabilis* is too well known to need any recommendation. It is not, however, generally known that it is excellent for pot culture. Good strong pieces should be potted up now, and the pots plunged in ashes for a short time, similar to the treatment given to bulbs in pots, to encourage root growth. Then the plants may be gently potted, and will come into bloom early in the New Year, or they may be grown under cooler conditions, coming on later before the outdoor flowers.

A Charming Combination of Pink.—A few days ago we noticed a rather unique but effective combination of perennial and annual flowers. The bed was a large, circular one in a broad expanse of lawn. In this the Japanese Anemone known as Queen Charlotte had been rather sparsely planted, and between the plants the pink Mallow, *Lavatera rosea splendens*, had been sown. The soft pink of the Mallows harmonised perfectly with the rose pink blooms of the Anemone, and created a study in these shades that might well be emulated in other places. We understand that the Mallows were sown in the bed early in April.

A Good Autumn Rock Plant.—One of the most attractive rock plants of recent introduction is *Corydalis Wilsoni*. This beautiful Fumitory, which is now a mass of flower, was discovered in China by the well-known collector after whom it is named. It is one of the best of the whole genus, with its erect racemes of large, deep canary yellow flowers, 7 inches to 8 inches in length, standing above the elegantly-cut, glaucous green foliage. It commences to flower early in the summer and continues throughout the autumn and the early part of the winter, providing the weather remains mild. It appears to be quite hardy as regards cold, but should be planted so that it gets some shelter from an overhanging rock.

The Destruction of Wasps' Nests.—The following note, culled from a daily paper, is of interest and value at this season, as it gives a simple and efficacious means of reducing the wasp pest: "Having been connected with fruit cultivation for thirty-eight years, I have found the most simple and efficient way to destroy wasps' nests is by using the following method: During the day locate the nest and note if there is more than one entrance to the same. Procure an ordinary wine bottle and put in a pint or more of paraffin oil, and as soon as it is dusk take a lantern, find the hole, pour in the oil, and push the neck of the bottle into the hole and leave it. There will not be a wasp alive by the next night, all being destroyed by the fumes. It is not often there are two entrances; if there are, block the top one up securely."

CORRESPONDENCE.

The Editor is not responsible for the opinions expressed by correspondents.)

The Best White Bedding Rose.—Like Mr. H. E. Molyneux (page 443), I should unhesitatingly select Molly Sharran Crawford and Mrs. H. Stevens as the best white bedders. My White Killarneys are simply bad from mildew, and I am not going to harbour these, Mine, Jules Grolez, Bessie Brown, and a few other notorious mildewers among my main body of plants in future. I must grow some, but they will be kept in a distant part by themselves, and probably go through the "kill or cure" test.—A. P.

Campanula lanata in Ireland.—The accompanying illustration, from a photograph kindly sent us by Miss Stokes of Baily, Dublin, represents a fine plant of the comparatively rare *Campanula lanata*. The plant is 2 feet 6 inches high and 3 feet 1 inch in diameter. Miss Stokes says: "The plant was raised from seed brought from Bulgaria, and has lived two years without protection, but this is the first year it has bloomed. Other plants raised from the same stock of seed have pale pink flowers."

Musk Losing Its Scent.—May I add another instance of Musk losing its scent to those already sent by correspondents of THE GARDEN? This is an old garden, and the place was formerly the residence of my grandmother, who died in the early eighties. Before that I know that the Musk which grows all round the step of the greenhouse had a delicious scent. It seeds freely, and has established itself in many odd corners; but since I came to live here ten years ago it has never had any scent at all, although I have examined it carefully many times.—M. E. CURLE, *Melrose*.

A Veteran Cyclamen.—As our July corresponds with your January, I have just been reading THE GARDEN for January 18, in which you mention a Cyclamen plant, the age of which was twenty-five years. I can easily beat you, for my friend, Mr. John Enys of Enys, Cornwall, in riding over the Holy Land, dismounted to take up a plant of

Cyclamen. He afterwards came out here, where he lived many years. At one time, on leaving to pay a visit to England, he gave me the plant to take care of, saying he had had it thirty years. I put it in my greenhouse, where it bore seventy-two flowers at once. On his return he said I could keep it, but it only lived two or three years more.—EMMA T. IZARD, *Whanaka, Christchurch, New Zealand*

The Midland Daffodil Society.—With regard to the continuance of the heretofore annual dinner of this society, referred to by Mr. Adams in your last issue, kindly allow us to say that, although when approached we agreed to subscribe to it, on more mature consideration we are strongly of opinion that it would be inopportune to hold the dinner in 1914, while the calamity of our host's death is still so fresh. The matter, however, is scarcely suited for discussion in your columns, but

must be decided by the committee of the society—P. D. WILLIAMS (President, Midland Daffodil Society), G. H. ENGLEHEART (ex-President).

Rosecea purpurea Flowering Outdoors in Scotland.—One does not often see the distinct *Rosecea purpurea* in the open in Scottish gardens, but I came across a good plant in bloom the other day in an Ayrshire garden. One cannot well call it showy, but it is an interesting plant, and one of the few of its class to be met with in outdoor gardens. It will never find favour with those who delight only in showy plants, but the formation of the flowers is unlike that of most border subjects, and the deep purple blooms among the lanceolate leaves are attractive in their way. I can count the Scottish gardens in which I have met with it as a hardy flower on the fingers of one hand, although one has seen it rather more frequently in places where it was protected in winter. A freely-drained, rather porous and sandy

soil apparently suits it best, but it must not suffer from too much drought in summer.—S. ARNOTT

until rooted. Take them out about November 12 to 15. Put them at once in a dark, moist place in a greenhouse, avoiding any bottom-heat, and give them a temperature of between 70° and 80°. When the stems have grown and the flower-buds are plainly visible on their pedicels, the plants must be gradually exposed to the light. The temperature must still be kept at from 70° to 80°; in fact, it must not be altered until the flowers are expanded, when it may be reduced somewhat for a day or two before the pots are brought into the dwelling-house or a cool conservatory. L'Innocence, General Pelissier, Grande Blanche, Gertrude and Marie are well suited for this particular culture. The last two require a rather longer period in the hothouse before they will bloom than the first three.—JOSEPH JACOB.

A Good Dry-Soil Rose.—That splendid variety Hugh Dickson has done remarkably well this year in a very light, sandy soil. For several weeks during July a large bed of plants yielded grand blooms, and by the second week in August commenced to flower on young shoots which were very strong. While many varieties growing near them are now badly mildewed, the plants of Hugh Dickson referred to are quite free. I have seen this Rose growing up the branches of large shrubs and trees in a garden just the same as Hybrid Teas grow—unpruned except for the thinning out of weakly shoots. The flowers were lovely, and there were plenty of them.—G. G.

Rose Irish Elegance.—In your issue of August 30 I have seen that "A. B. Essex" would be pleased to know the opinions of other readers on Rose Irish Elegance. I had one planted in December, 1910, here, on the seaside, against a wall facing west. Since the first year the plant has given me entire satisfaction, and has been the admiration of all my friends. Later on I purchased some more, which have been planted in other parts of my garden, and everywhere this variety has proved to be a free-blooming Rose, bearing the flowers since the beginning of May until almost the end of October. It suffers a little from mildew, but with a small quantity of sulphur it again recovers good health. It seems to me to be a good pillar Rose, and

my first plant is now more than two metres high.—J. NESBITT, *Praia de Granja*.

— "A. B. Essex," on page 430, asks for the opinions of your readers as to the merits of this Rose for the garden. If grown intelligently, there can only be one answer to that question. Admitted that the life of a full-blown flower does not exceed forty-eight hours, yet it flowers so freely that my plants of it are rarely without a bloom from May to November. As a matter of curiosity, before sitting down to write this note, I made a special journey to inspect my plants. I have growing here the original plant (I believe the first one to be planted outside the nursery of the raisers). It is nine years old, and is a bush 6 feet high and 4 feet through, carrying at the moment seventy-five buds and flowers with the promise of very many more. Of course, that is an exceptional plant, but the Rose is one

A FINE PLANT OF A LITTLE-KNOWN BELLFLOWER, CAMPANULA LANATA, IN A READER'S GARDEN IN IRELAND.

FIVE GOOD NEW
NARCISSI—

1. Ethelbert.
2. Florence Pearson.
3. The Doctor.
4. Utopia.
5. Dream.

that will do well in almost any situation. It shaded from the sun (mine are planted under a 6-foot fence and face due west), the colour will remain in the flowers till the petals drop. The contrast of the buds and flowers with the foliage, its wonderful vigour of growth, its usefulness for table decoration and the individual beauty of its blooms all go to make it one of those Roses that should be in every garden. The only possible objection to it is that it is "only a single," and that, I know, is a fatal one to many. For myself I am inclined rather to the opposite view that for pure beauty one must go to the single Rose to find it, and of all single Roses Irish Elegance is entitled to pride of place. Whether Irish Fire-flame will presently depose it or not remains to be seen. I am inclined to think that it will always be difficult (and purely a matter of taste) to decide between them, and the only solution will be to grow them both.—HERBERT E. MOLYNEUX, *Southampton*.

— I read with interest the note by "A. B. Essex" in THE GARDEN of August 30 on Rose Irish Elegance. It has flowered freely with me, having started early in the year, and is still in bloom and making nice growth. Everyone falls in love with it. As my garden is only a few feet square, the soil sandy loam, and faces north, I think this speaks well for it.—R. F. L. *Surrey*.

— In your issue of the 30th ult., "A. B. Essex" asks, "Is Rose Irish Elegance free-flowering?" I have grown this Rose for four years in my garden in Montgomeryshire (600 feet above sea-level), and my answer is decidedly in the affirmative. My only tree is very vigorous, and now has a leading shoot of this year's growth over six feet in height, crowned with eight buds and two open flowers. The tree has at present about twenty other flowers or buds. At the latter end of June it bore at least as many as, or more than, the present crop, and it had a period of rest lasting about a fortnight. The tree stands in the face of the south-west gales, which are very strong here, and requires, therefore, to be well staked. This has been truly a wonderful Rose year. There has been very little trouble with green fly, but the recent "muggy" weather, with heavy dews at night, has brought on mildew, and I have had a severe struggle to keep it in check. With so many blooms on the trees it is impossible to syringe them, and I have been obliged to resort to sponging the leaves with a weak solution of formaldehyde, dusting the worst affected leaves or stems with flowers of sulphur afterwards. The Rambler Roses have been particularly prolific. The masses of bloom on Dorothy Perkins have been wonderful.—EDWARD R. PICOLMORE.

— Your correspondent "A. B. Essex" asks in your issue of the 30th ult. the opinion of other readers as to the merits of Rose Irish Elegance, especially as to its being free-flowering or the reverse. I can only say that in my garden, and still more in that of a neighbour, where the soil is better, it is almost, if not quite, the most free-flowering Rose I know. It begins with the earliest Roses, goes on with the latest, grows into a fine bush, and is generally covered with bloom. Its blooms are fugacious, that no one can deny, but the extreme beauty of the buds, especially when half open, quite makes up for that, I think. Perhaps "A. B. Essex's" friends may have made the mistake of pruning this Rose, which should never be done after the first year. Only the dead and weak wood should be cut out.—C. E. LOGAN *ELMSLIE, Farnham, Surrey*.

BEAUTIFUL BULBOUS GREENHOUSE PLANTS.

THE NERINES.

THOUGH this beautiful genus of Amaryllidæ has been cultivated for more than a century and is remarkably free from many of the diseases and difficulties which attend the cultivation of many bulbous plants, it has received very little attention, except from a few amateurs. As I have made rather a speciality of Nerines for over thirty years, and have been able to improve them to a very great extent in variety of colour, size and form of individual flowers and of the truss, and especially in their freedom and regularity of flowering, in which the old *Nerine sarniensis*, commonly known as the Guernsey Lily, is so deficient, I am able to give some hints on their cultivation which may be useful to others.

The wild species of *Nerine* are all natives of South Africa, but we know very little of their life-history or the conditions under which they grow there. Herbert, in his admirable monograph, describes the species and hybrids known seventy years ago, since when no novelties of sterling merit have been introduced, and it seems to me that unless fresh blood can be discovered, we have nearly reached the limit of possible improvement. A great many of the names recognised as specific are, in my opinion, quite unworthy of such rank, and, as all the species hybridise with more or less ease in cultivation, we may reasonably suppose that they have done so in Nature also. From time to time so-called species or hybrids have been selected, such as *Planti*, *coruscans*, *atrosanguinea*, *Meadowbanki*, which were superior to *sarniensis*, and probably derive their improvement in a great measure from *Fothergilli*, which remains the king of the true species. But the immense variety of colour which I have now obtained by intercrossing hybrids, ranging from crimson through all shades of mauve, pink and red to pure white, is so great that they have almost attained the stage of florists' flowers, and many of the seedlings which have been named, in deference to the rules of the Royal Horticultural Society's floral committee, are so near each other that they require a specialist to distinguish and judge them, just as much as *Narcissi* do.

What is a Good *Nerine*?—The standards of merit which I require in a *Nerine* are, first, that the six segments of the perianth shall be regular in shape and position, as in *Fothergilli*, and not irregular or narrow as in *flexuosa* and all the hybrids derived from it, of which *Manselli* is one of the best and one of the most floriferous. For this reason I do not look on *Bowdeni*, a recent introduction which is superior in size to any except *Fothergilli*, as a desirable parent of hybrids, though it may serve to prolong the flowering season, which is an important element in a collection of *Nerines*. Formerly, September and October were the season of flowering of all the older species, but now the latter half of October is the time at which in normal seasons I have the greatest show in my *Nerine* house. Secondly, colour, which, whatever its shade, ought to be clean, pure and sparkling with the diamond-dust-like particles which make a *Nerine* so beautiful in sunshine. All shades of pink, cerise and scarlet are easy enough to get, but very dark and very pale shades are not so common, for though the crossing of *pudica* has produced many of them, they are often deficient in size and form. A pure white *Nerine* of good shape has long

been my great object, for though I have heard of white forms of *Nerine* in South Africa, the only one I was ever able to get until I raised *Snowflake* was *flexuosa alba*. The delicate waving of the edge of the petals, which is such a beautiful feature in *Mrs. H. Elwes*, *Countess Bathurst*, and others of my raising, is a matter of taste, but adds much, in my opinion, to the beauty. But no *Nerine* which does not flower annually under proper treatment should be looked on as perfect, shy flowering being the great defect of many of the older imported forms, which often produce only two or three spikes from a pot of ten or twelve full-sized bulbs; whereas all my best hybrids flower annually and sometimes produce two spikes on a bulb. One of the finest hybrids raised by Mr. Elliott was *Purple Prince*, but it had the great defect of flowering only at intervals of some years, though many that I have raised from it as the male parent are, under similar treatment, quite free bloomers. *Leichtlin's* best hybrid *Novelty* was a first-rate variety, though the flowers showed too much of the irregularity of *flexuosa*, just as *Manselli* and *tardiflora* do. Few, if any, of the numerous hybrids which have been raised and named at Glasnevin come up to my standard. Mr. Godman is now raising some nice hybrids, and *Mrs. F. D. Godman*, which I raised ten years or more ago, is one of the best colours of all. *Miss Willmott* is also a beauty, but hardly distinct from some seedlings of *Meadowbanki*.

The Cultivation of *Nerines* is simple enough if a few leading points are attended to. First, they require a position near the glass in a cold, unshaded greenhouse, with plenty of air during the growing season, when the thermometer should never be allowed to fall to freezing-point or to exceed 50° to 60° except in full sunshine. Secondly, they must have regular and liberal watering during the growing season, the object being to develop as many sturdy, fleshy leaves as possible on a hard, firm bulb. This is best obtained by growing them in moderate-sized, well-drained pots, in which the bulbs are about half covered with good, light, but not too sandy loam, and feeding them when the pots are full of roots, with soot-water or weak liquid manure. As soon as the leaves begin to turn yellow, in April and May, water must be discontinued, and as soon as the leaves have quite withered, the pots may be turned out into a cold frame, where they must be kept dry till the spikes begin to show in September or October. It is well to stand the pot in a pan of water when growth commences, in order to moisten the dry soil thoroughly from below. Any offsets can be taken off when repotting is done in August, and though the bulbs will continue to flower for many years without repotting, I find it best to do so about once in three years, as, if left too long, the offsets low down in the pot force the older bulbs in the centre right out of the soil and do not flower simultaneously with them.

Seed Should be Sown when ripe, and the young seedlings kept in a warmer house for two years at least without resting or drying them off. Under this treatment they will flower in much less time than if kept in the same house and ripened off with their parents. Mealy bug is the only insect pest which has ever troubled me, and when its presence is detected by the pale spots on the young leaves, the bulbs must be thoroughly cleaned with some insecticide, as in the resting season these insects often get down to the bottom of the pot among the roots. It once this pest is allowed

to spread, it becomes very troublesome, and any plants which show traces of it should be kept in quarantine and examined carefully at short intervals. If any bulbs become soft or rotten, which may be due to overwatering or want of light and air, they should be turned out of the pot at once and destroyed; but this rarely happens unless they are grossly neglected. For dinner-table decoration in the autumn I know of few, if any, plants which surpass *Nerines*, because their colours show up so well under a strong light, and a variety of different shades make the effect much better than when only one kind is grown. In the warmest parts of England *Nerines* may be grown fairly well in a cold frame all the year round, but in my experience better in pots than planted out, as I have never seen them in perfection so treated.

H. J. ELWES.

TULIPS IN GRASS.

MY request for information on this subject, which the Editor so kindly inserted in the issue of April 19, has brought a good many interesting replies, including two from America and one from Germany.

What follows is a sort of "resurrection pie" made from their ingredients.

The experiences recounted by the writers are various. From them, however, one or two facts may be gleaned. First, that the flowers from bulbs left in grass are much smaller than those from lifted or cultivated ones. Secondly, that the continuation of their blooming more than two, or possibly three, years depends upon the soil. Either a good rich compost must be made and introduced under the sod to plant them in, or an annual top-dressing must be given, or the land must be naturally suited for Tulips. Thirdly, that if there is a continuation of blooming at all, it is not the monopoly of any one particular type, for earlies such as Cottage Maid and Thomas Moore seem to be just as amenable to this method of growing them as are *gesneriana* *spathulata*, *retroflexa*, *fulgens* and *sylvestris*, neither more nor less.

The majority of letters reported an experience like my own. The blooms become smaller and fewer, and after the second year there are none at all. An American lady writes: "My experience is precisely yours. I cannot get more than one crop from Tulips grown in grass, though they are magnificent in beds, and I have given up in despair. . . . In 1911 I planted forty bulbs in grass just to see. I saw forty single leaves yesterday."

A Scotch writer says: "I have not tried a great number, but most of them behave as stated in the note. The exception with me has been *T. retroflexa*, which still gives a few flowers after nine or ten years, and it flowered regularly for five or six years." Mrs. Francis King (America) records her experience thus: "I have had for years a pretty planting of Vermilion Brilliant under Apple trees, but each year I must replant, or very little happens."

A gentleman from Hembury planted a dozen large clumps three and a-half years ago, and "they show no sign of going off." Then came the post-script, "I ought to add that a good bed was made to plant the Tulips in. It planted through the turf I expect there would be failures."

At Lockinge (Wantage) much the same preparation was made two years ago, but, instead of being sodded, "the beds were sown with grass after the Tulips were planted; in fact, when they were

through the ground." These two instances seem to prove that it is possible to have a brave show of Tulips in grass for a certain number of years if pains are taken to give the bulbs a well-prepared and fairly rich rooting medium at the time they are planted.

A most interesting communication came from Sir A. B. Hepburn, who ten to thirteen years ago planted in his park at Smeaton-Hepburn in East Lothian "a lot of common garden Tulips among the grass on the side of a walk. Most (he says) have, I think, survived, though how many I put in originally I cannot say. Be that as it may, there are quite a lot, and they come up regularly every year—white, red, yellow—sadly reduced in size, but still making pleasing dots and patches of colour." In answer to my query about soil, the same gentleman was kind enough to send me a second letter, in which was this passage: "As to soils, I have them in heavy and in light loam. There is a good deal of felspar in the soil. The subsoil is boulder clay." He remarks that it "holds moisture most of the year."

A cutting from an American paper records how 27,000 early bedding Tulips were planted five years ago at Kansas City, Mo., "in holes made with a pointed spade-handle three inches under the sod. . . . To-day these Tulips are flowering almost as good as they did the first year." These and some similar instances, which space forbids me to quote, seem to show that there are a few lucky people who have soil which naturally suits Tulips, and in which, if the leaves are left to die down naturally, they continue to bloom for a certain number of years.

Of more than ordinary interest is the example from Dundalk of Tulips in grass perfecting their seeds and giving rise to a few self-sown seedlings. The writer states: "Those on the level have died out, but a few bloom each year on a mound about three yards high. The grass on this is very poor. Some have appeared from seed a few yards away in grass under small trees." I wonder what the sod is like in those centres at Aix, Florence and elsewhere, from which new neo-Tulips (*Mauriana*, *Billettiana*, *Marjoletti*, &c.) are from time to time collected. Should this meet the eye of anyone who personally knows those spots, it would be nice of them if they would tell us in the Correspondence columns of THE GARDEN what sort of herbage is to be found there. Summing all up, it appears that, under normal conditions, Tulips, when planted in grass, get beautifully less and less in quantity and smaller and smaller in size; only in a few favoured spots do they continue to bloom for any length of time. It is, however, possible to so ameliorate the rooting medium in which they are placed that they will give a good many years of bloom. Possibly species or varieties immediately descended from species "do" rather better than other kinds.

JOSEPH JACOB.

A CHARMING CROCUS FOR THE ROCK GARDEN.

ALTHOUGH there are a number of *Crocus* species well adapted for growing in the rock garden, I have not found one to surpass in beauty and interest that known as *Sieberi*. It is one of the earliest to flower in the New Year, and if given a sunny nook the pale lavender blue flowers will open and reveal the beautiful orange scarlet stigmata. In common with other *Crocuses*, it needs planting in groups of not fewer than a dozen corms if a good effect is to be obtained.

A. B. ESSER.

BULB LISTS.

LIKE bedtime when one is reading a good book or the dressing-gong on a summer's evening, the bulb lists catch one unready, in the height of enjoyment of well-filled summer borders. Yet if one does not grapple with them at once and send off the resulting orders early, two evils are sure to accrue—someone who is more prompt in ordering gets the best bulbs, and even the fairly good ones we do get later on are not improved by having been kept out of the ground. Yet, however much we realise all that, it is not easy to bring on an attack of the bulb-planting fever when one's borders look so full and it is hard to think out space for planting. I have tried to make a stern rule for myself that I will not order any plants I have not fixed on a suitable site for; but I break it whenever I see something I feel I cannot live longer without, or when I get certain of the more tempting bulb lists. How can I resist a Darwin Tulip that is new to me and described as glowing salmon or tender lilac? It is enough to make one hope something will die and leave a gap to be filled.

I try each season to plant a fresh colony of certain Snowdrops. They flower so early, often in December if one gets collected bulbs planted before September has brought death to a partridge. *Galanthus byzantinus* is one of my favourites for this purpose, and any of the forms of *Elwesii* are worth the same early-to-bed treatment. Not only do they flower before their relations in older plantings, but these early-planted ones settle down and do much better than those that have been kept out of the ground. I believe it is the secret of success in planting Snowdrops, *Anemones* of the *memorosa*, *blanda* and *apennina* races, Winter Aconite, Crown Imperials, *Erythroniums* and, of course, *Narcissi*, to order them as early as possible and plant them at once, or sooner if possible, as the Irishman said, after their arrival.

Of newer plants that I have tried lately I can fully recommend the new race of bulbous Irises called Dutch Irises. They are larger and earlier than Spanish Irises, and some I left unlifted for three years in a warm south border have increased wonderfully and flowered well each year. Some I cut rather freely, with long stems, have not made such good bulbs as those left uncut, but how I did enjoy the vases full of them! Some of them show distinct traces of *I. tingitana* as a parent, and are almost as lovely as that wayward, shy-flowering beauty. They originated in Messrs. Van Tubergen's nursery in Haarlem, but will, I expect, soon be in every other. I was greatly pleased, too, with *Cyclamen repandum* roseum, from the same firm, a free-flowering spring *Cyclamen* of a soft shade of rose. *Crocus vernus* Margot is another thing I try to find room for an additional big clump of each year. Its soft lilac is charming. *Colchicum speciosum album* is now to be bought for 6d., and, being one of the loveliest of all bulbous plants, should be in every garden; but if you want it to thrive, catch the next post and send an order to Messrs. Backhouse for it. They raised it from a single bulb that appeared in their nursery, and for some years after I first saw it there it was only possible for millionaires to think of purchasing it. I find it one of the consolations for growing old that sixpence can now be changed for this white flower of the autumn.

Scilla nutans *deheata*, a wild Hyacinth, pearly white, with tender blue shading and a long, drooping

head of flowers, is worth keeping a semi-shady corner for; and if you can find two such corners, plant a clump of its brother, *S. n. Robin Hood*, a rosy, coral-tipped form, in the second one.

If you do not know those two grand old Tazettas, *Polyanthus Narcissus Bazelman major* and *Muzart orientalis*, you should try them, and they will give you a thrill I promise you, planted in some warm south border. Do not forget *Tulipa Kaufmanniana* for a sunny spot, planted at least 6 inches deep, if you want to be reminded of Water Lilies in April, or *T. Sprengeri* if you wish to prolong your Tulip season into the first days of June. Its brilliant scarlet is only eclipsed by *Habranthus pratensis*, which you must also order if you have a cosy empty corner in front of some greenhouse where the pipes inside help the warmth-lovers outside. Of plants not bulbous as to their root systems,

is very distinct, having drooping flowers that remain tubular. There is also a white form of it that is a good companion to the other. I think the plants I have named would be worth adding to any collection. The bill for them need not be a ruinous one, and as they should all settle down and improve year by year, it would be money better spent than on the one-year show to be derived from many of the early Tulips and bedding Hyacinths, beyond which the minds of many gardeners refuse to go when making out the autumn bulb list.

E. A. BOWLES.

MAY-FLOWERING TULIPS UNDER YOUNG APPLE TREES.

The accompanying illustration depicts a method of growing Darwin and other May-flowering

might be made of them for indoor decoration. We like to have them loosely arranged in large, old-fashioned bowls or vases of soft colour, and so far have found nothing to equal those made in Cornwall of the same material as the famous Cornish pitchers. Whether planted in large masses of one colour, or as a mixture, these May-flowering Tulips never appear incongruous. When sending us the photograph, Messrs. Wallace wrote: "Amateurs would be surprised at the beautiful effects to be obtained from bold plantings of Tulips under orchard trees, as shown in the accompanying illustration. The bulbs are protected to a considerable degree from their worst enemies, late frosts, cutting winds and heavy rains, and the flowers themselves develop more steadily and last longer, thanks to the thin shade cast by the trees. It is not easy to produce an ugly mixture

A BEAUTIFUL GROUPING OF MAY-FLOWERING TULIPS UNDER YOUNG APPLE TREES.

but for autumn ordering, are two out-of-the-way things that add interest as well as beauty to the garden. First, the dazzling scarlet wild *Ranunculus* of Palestine, *R. asiaticus*, often listed as *Single Scarlet*, is a grand thing. I think it prefers a light soil, but some well-rotted cowyard manure dug in for the roots to go down and find, and the tubers should be lifted and stored away dry as soon as the leaves die off.

Agapanthus intermedius is a better thing in hardy blue African Lilies than the older *A. minor mooreanus*, and if a little mound of ashes is placed over the clump in bad winters, should prove quite hardy in a south border. *A. Wellighii* is also hardy enough for the same treatment, and

Tulips that has a great deal to commend it, but which, so far, has not been extensively adopted. In the gardens at Hallingbury, near Bishop's Stortford, which we hope to illustrate and describe in some subsequent issue, large quantities are very effectively grouped under young Apple trees, the flowers of which are open at the same time as those of the Tulips. The illustration which we publish herewith represents Tulips under young Apple trees in Messrs. R. Wallace and Co.'s nursery at Colchester, and gives an excellent idea of what might be done in many newly-planted orchards. When grown in this way there is always an abundance of long-stemmed, stately flowers for cutting, and as these last well in water, more use

of Darwins, and sometimes a chance planting gives unexpected pleasure in a fine contrast or harmony of colour. The lavender of *Remembrance*, for example, is very fine with the rose pink of *Suzon*. The soft pinks also go finely with the blackish maroons and dark purples, although, of course, the yellows from *Vitellina* and other May-flowering varieties give stronger contrasts with these blacks, crimsons and purples. Our beds are 4 feet wide, and each variety is represented by several hundred bulbs. Imagine 100 or 200 varieties representing as many different shades all flowering at one time, and your readers can appreciate the glorious riot of colour which is created in April and May."

POETAZ NARCISSI.

ALTHOUGH wonderful progress has been made in the world of Daffodils during the past ten or fifteen years, there has been no more important or far-reaching break than that obtained by the Rev. G. H. Engleheart when he successfully crossed *Poeticus ornatus* with the best forms of *Narcissus Tazetta*, of which Paper White and Grand Mouarque are, perhaps, the best-known examples. The result of this cross was an important race of *Narcissi* with the hardness and fragrance of *ornatus* and the free-flowering properties of the *Tazetta* type. The size and even contour of *ornatus* were also transmitted to the hybrids, so that in such varieties as *Aspasia*, an illustration of which is reproduced herewith, we get a number of flowers almost as large, perfect and fragrant as those of *ornatus* on one stem. The effect produced by a well-

THE DAFFODIL FLY.

(*MERODON EQUESTRIS*.)

SINCE writing the article published in *THE GARDEN* of April 26, 1913, I have continued the study of *Merodon equestris* and gained considerably in knowledge and experience of it. It has appeared in greater numbers this year, and I have literally been "surrounded by a host of foes."

The Larva.—We are apt to charge the fly with aggressiveness, whereas it is the larva which is so destructive. The latter, in the preparation of its domicile, excavates its way into the Daffodil bulb, and this excavation is its dining-room, drawing-room, dormitory, scullery, &c. There in wanton selfishness it devours and destroys the very fabric in which it dwells. Its gluttony is insatiable; it is a recluse, receiving no visitors and holding no intercourse with its relations or

then stretches out its neck again for a fresh grip. The mandibles are used in the same way as a sailor uses a kedge to warp his vessel along.

The Chrysalis.—After the New Year has made its appearance, the more mature larvæ make preparation for their change to the chrysalis state. First a slight discoloration appears, which gradually spreads over the whole surface of the body. While this is taking place, the grub works up into the neck of the bulb, and sometimes, after remaining in this position a short time, rises into the soil above, and stays there until its change is completed. The outer skin now hardens and a horny case is formed, and, following a further period of waiting, two short horns rise from the head. I have not discovered the purpose of these horns, but they have the appearance of projected eyes. This stage of transition depends in a great measure upon the weather, but occupies about eight weeks.

The Fly.—When the time to change from the chrysalis state arrives, the living creature bursts away two sections of its outer skin and emerges a perfect fly. This is Nature's provision for the propagation of future generations. There remain the two sections of the shell. On one of these are the two horns, in the other the cocoon, which was the creature's protection against chills during its metamorphosis. The year 1911 was very warm, and, consequently, the insect world was most active in propagation. As the year advanced, having found the two year larval period, I prophesied that 1913 would be a revelation in fly increase, and this proved to be the case. So numerous did the fly become during the current year that it attracted the notice of people who had previously been strangers to its existence, and I had enquires from, and was called to identify it in, places where it had never been noticed before. Questions have been put as to the reasons of its visits and where it comes from; but it is a perplexing subject, and I am compelled to admit my inability to give a satisfactory answer. I myself could ask a score of questions, such as, Does it migrate when the locality becomes over-populated, like rats,

NARCISSUS ASPASIA, A BEAUTIFUL POETAZ VARIETY, IN A SURREY GARDEN.

grown group of these is well shown in the illustration, which is from a photograph taken in Mr. W. A. Bilney's garden at Weybridge. In addition to their value for garden decoration, these Poetaz *Narcissi*, as the race is appropriately called, are admirable for growing in pots or bowls of fibre, while for cutting they are ideal. Fortunately, most of them are good growers, and bulbs of *Aspasia* and *Elyra* can be obtained for about 1s. 6d. per dozen. A newer and very handsome variety is *Jaune à Merveille*, which has a large, broad perianth of soft primrose colour, the yellow cup or eye being thinly edged with orange. As yet it is rather expensive. In addition to *Aspasia* and *Elyra*, both of which have white perianths and yellow cups, there are *Ideal*, white, with orange cup; *Irene*, pale primrose and golden yellow cup; *Klondyke*, yellow perianth and eye; and *Triumph*, white, with yellow cup. For the amateur who has not yet tried this excellent race, *Aspasia* and *Elyra* are excellent.

B. A.

neighbours. To it time is a meaningless term, and for nearly two years it awaits its metamorphosis, filled to repletion. In the article referred to I mentioned two grubs found, one in April and one in May. I collected others later on and kept a sort of menagerie, repeatedly examining and inspecting them under the microscope. They were constantly overhauled, drawings made of them in repose, travelling, turning over, &c., and in this manner I obtained many refreshing surprises in a most interesting study. The organism of *Merodon equestris* is wonderfully adapted to its peculiar life. I discovered that the larva has two eyes; mandibles, by which it does all its excavating, and which form the basis of its powers of locomotion; and a very flexible top lip, at the sides of which are a pair of feelers, which it runs over the surface of its path. The fore part of its body is very mobile, and can be stretched out to a great extent. With its mandibles it grips the surface on which it lies and hauls itself forward;

mice and rabbits? I have found the fly this year in lanes, feeding on wild Hemlock; in the neighbourhood of houses, in railway stations, in fields, on grass, &c. The subject is engaging the attention of members of Daffodil societies at their conventions; but while they are talking, the fly is propagating, bulbs are dying, and growers are suffering. Meanwhile a wage constant war, give no quarter, lose no opportunity of doing what I can for its destruction, and rest not from the pursuit. At the same time I am extending my observations. Early this year I discovered the flies' forage ground. Their needs are farina and nectar, which are found in flowers, and where there are masses of flowers there will the fly be found. At a bed of yellow Marguerites, while they continued in bloom, I watched. The enemy came, but never returned after I invented and used a smaller net to work inside the one mentioned in my previous article. I had no hunting, no chasing; they came in such numbers that I killed as many as sixty-two in

one day of three hours' work. I saw one on a flower, got it between the nets, quickly shut them together, and the fly was a captive. I noticed that prior to June 12 the flies, like the antediluvians, seemed to have no object in life but to play at "catch who can," "hide and seek," and "eat and drink." After that date they became amorous, and love scenes were daily witnessed. Scotch law was prevalent, and before two or more witnesses the ceremony was perfected, while the song of joy and the hum of contentment filled the air. Before long my garden was literally cleared of them; but subsequently, at two periods with about a fortnight's interval, I was visited by six females, each seeking a home for their expected families. In killing these I was careful to find out whether the eggs were matured. Only one was ready for laying; in the others the eggs were not matured.

The marvellous construction of *Merodon equestris* is evidence of the supreme wisdom of the Omnipotent Mind. I made careful investigation and found the fly has three eyes, or ocelli, in a triangle at the back of its head, which are useful in cases where an enemy approaches while it is in a flower. Bees have these ocelli, and it was a revelation to me to find them in the *Merodon*. The size of the ocelli varies a little in the sexes, those of the female being slightly larger, and clearer from short hairs as a rule. The sexes always vary in size and markings, according to age. The male develops more of a foxy appearance, while the female exhibits more grey about the posterior. The female, too, at full maturity is one-eighth of an inch longer than a fully-matured male. I found a difference in the femur, or thigh portion, of their hind legs. That of the male has three horny projections, while that of the female is quite smooth, and if a fly is held in the hand it is possible to tell the sex by the way it irritates the skin. Both male and female have a horny substance on the back at the waist, under which is an air-chamber, while their wings are lengthened at the base by a mechanical arrangement, the edges of which are fringed with black hairs curving gently downwards and inwards. I reason from this that the air entering and leaving the chamber produces the whistling, humming sound one hears as the fly rushes through the air, and that its purpose is to intimate its whereabouts to its kind.

I have spent an enormous amount of time on my investigations relative to *Merodon equestris*, and *THE GARDEN* readers have now almost as much information of it as I myself possess. Read my previous article in conjunction with this, and we have a great advance in our knowledge. It is, of course, unnecessary for me to say anything in regard to the destruction of the larvæ, but I strongly press the necessity of the destruction of the fly. We are yearly reminded in the spring of the destrability

of killing queen wasps, and so reducing the number of nests; but to Daffodil-growers the destruction of *Merodon equestris* is equally important, as every female fly destroyed prevents the deposit of from fifty to sixty eggs, which would ruin a similar number of bulbs; and I call upon every grower to act. Remember the foe is at the gate, and can only be vanquished by prompt and earnest attack. The plan I recommend is the use of two nets as mentioned; this is a wonderfully successful method of catching the fly. I ask any reader finding small larvæ up to the time of planting to send me a few. May I remind readers that this is the time to look for them. Seasonable precautions just now are: Rake over your beds, leave no holes for the

was dead. Has any reader tested this cold water bath? In the case I refer to, the bulbs were in water forty-eight hours. The larva which left the bulb subsequently died, but the other two show no sign of suffering. GEORGE ST. OX.

A DAINY DAFFODIL.

(*NARCISSUS TRIANDRUS CALATHINUS*.)

The little Daffodil named Angel's Tears is widely known by virtue of its grace and beauty, but its close relation which forms the subject of this note is not so well known as it deserves. It grows to a height of about seven inches, and is one of the most beautiful little Daffodils in existence. It is useful alike for growing in pots or for filling a sheltered pocket in the rock garden. A well-drained, gritty soil and a half-shady position seem to suit it best; but if the bulbs do not flower the first year after planting, they should be left undisturbed to establish themselves. There is a touch of interest concerning the native habitat of this variety. It was found on one of the Gléneau Isles some years ago by that assiduous collector of Daffodils, the late Mr. Peter Barr. The collecting, it is said, was attended with a good deal of risk, but the most unfortunate part is that this gem is no longer to be found there, the sea having washed away all trace of it. Happily, there is a fair stock in cultivation, and it may be successfully raised from seed.

NARCISSUS TRIANDRUS CALATHINUS, A BEAUTIFUL VARIETY FOR POTS OR THE ROCK GARDEN.

WEEDING OUT WEAK-GROWING DAFFODILS.

NOW that we have such an enormous number of really good Daffodils, I think it is high time that a good many of the poor doers were done away with. I do not object to the common old things such as Princeps, Cynosure and many others; no doubt they have long since been eclipsed by better ones on the same lines; but, after all, they are good in their way, and are, at any rate, very cheap.

It is some of the newer and more expensive varieties which, I think, should be dropped; they may have pretty flowers, but the plants are so weak in constitution that not one in a dozen growers can do them well, and we may be sure that any good blooms we see at the shows have been culled from among a large number of poor, deformed or undersized flowers which were not good enough for table decoration, to say nothing of the show stand. Circlet, Egret and Cresset are just three which come to my mind. All these—and there are heaps more, one might add—bear pretty flowers when really well grown; but they have very poor constitutions, never make half enough leafage, and frequent blanks are to be seen in the rows.

females to get down to the bulbs. When buying, press your thumb against each bulb and refuse all soft ones. On Saturday, August 9, at 10 a.m., I placed five suspicious bulbs in water as a test. They remained there until 10 a.m. on the 11th, when I took them out. I found two bulbs good and three affected. In one case the larva had left the bulb and was alive at the bottom of the vessel; the other two were inside the bulbs, which were cut open. They were completely saturated, alive, and no worse for their bath. I put all three into a small jar with a bulb, and at 10 a.m. on August 13th one had worked its way partly into the bulb, one was quite well, and one

Of Poets there are legions; but how many make really strong growth and a good shapely bulb? Six or eight Poets would be ample for garden purposes if one could be sure of them all being good doers. I have made up my mind to gradually weed out all Daffodils of poor constitution, and if all growers would do the same, it would really be doing good work. It would be well if novelty-raisers would always keep in mind this question of constitution, and only work with good, strong-growing parents. By seeding varieties of weakly habit of growth, they have given us in the past many beautiful flowers, but plants which only one man in ten can grow.

Princess Mary has given numbers of good exhibition flowers, also numbers of things which will have to go to the rubbish heap sooner or later, because they take too much after their mother in the matter of poor health. I know there is another side to the question. A raiser may produce a new variety which is a really good plant on his ground, but which refuses to grow with the man he sells it to. That is no fault of the raiser, but bad luck for the buyer. Still, I would again urge upon hybridists the necessity for choosing healthy varieties upon which to make their crosses. With the great array of really good things in the Daffodil world already in existence, it is a pity to add anything which is not good all round; flower, length of stalk (some of my old friends will smile here) and habit of growth should all be good, or the new-comer should be relegated to the bonfire or the wild garden.

J. DUNCAN PEARSON.

The Nurseries, Lowtham, Notts.

NARCISSUS BRIGHTEYE.

This beautiful Narcissus, which was so well shown by Robert Sydenham, Limited, on several occasions last year, belongs to the Poeticus section, and, as its name implies, has a particularly bright yellow eye, with bright orange edging. The petals are broad and of good substance, overlapping well, so as to form a symmetrical flower of great beauty. It measures $3\frac{1}{2}$ inches in diameter. This variety, in common with many other excellent new sorts, was raised by the Rev. G. H. Engleheart. As Mr. Pearson points out in the foregoing article, there seems to be far too many of these Poeticus varieties, some of which are too much alike, yet it is difficult to see what can be done when raisers continue to give us so many good ones. Perhaps Mr. F. Herbert Chapman, who has done yeoman service in the interests of the "Poets," will let us have his opinion on the subject. The illustration depicts a fine vase of Brighteye as shown by Messrs. Sydenham in London last year.

THE CROWN OR POPPY ANEMONE.

(ANEMONE CORONARIA)

NONE of the many Anemones, or Wind-flowers, which adorn our gardens can hope to surpass in glorious colouring or in true value the beautiful Crown or Poppy Anemones, varieties of the Eastern *A. coronaria*. It has long held a high place in public favour, and those who are acquainted with the horticultural literature of the middle of the last century are well acquainted with the keen pleasure taken by the old florists in

Anemone coronaria tubers, although the work is a little troublesome. It is not, however, slow, as seeds sown in summer, as soon as ripe, will give flowering plants next summer, and those sown in early spring will give blooming tubers in the same autumn. In saving seeds, these should be taken only from blooms of the best forms and colours these being marked and the others not allowed to seed. The beds should be gone over daily, as if left the awned seeds will be scattered by the wind. As soon as the seeds can be detached without any pulling, they can be taken and spread on a sheet of paper in a sunny window or greenhouse for a day or two before sowing. If sown in the open, a

bed should be made up of loam, leaf-soil and sand; but loam and sand will do. It must be light, fine, and well drained. Little drills about a quarter of an inch deep should be drawn and the seeds sown in these. As they are very woolly they are difficult to separate, and this can best be done by mixing them and rubbing them with dry sand or fine loam, sowing them thinly in the drills and covering with about a quarter of an inch of fine soil. If the weather is dry, the bed should be watered and shaded until germination takes place, which will be in a week or so. When the plants have made a pair of their rough or true leaves, they should be pricked out in similar soil about two inches apart and grown on. Seeds may also be sown in pots or boxes, and the seedlings treated in a similar way to those in the open. They may either be allowed to flower where they stand or lifted when they go to rest and replanted in their flowering quarters.

The Best Positions.—If the best flowers are desired, the beds should be in a place where they are partially shaded, and the finest I have ever seen were partially shaded by Apple trees. The soil should be well dug and manured with old manure, preferably that from the cowshed, this being put beneath, but not touching the tubers, which may be planted 2 inches deep. If the position is not ready for the tubers when they are dried off, they may be stored in paper bags in a cool place beyond the reach of frost, or in dry sand. Tubers which have been purchased can be treated in the same way. Choice varieties can be propagated by division of the tubers when at rest, but seedlings give the finest blooms, as a rule.

Time to Plant.—The best time for planting is from September to the end of October in warm, light soils; but in heavy, damp ones it is wiser to leave this until February or March. By later plantings the season may be considerably prolonged, and by sowing seeds in early spring in a frame it is possible to have flowers throughout a mild winter by keeping the young plants under glass. The writer has sown seeds in a cold frame in March and has had flowers from October onwards. The St. Brigid varieties are the best for this purpose. A rich but light and well-drained soil is essential

NARCISSUS BRIGHTEYE, A NEW POETICUS VARIETY OF GREAT PROMISE.

the cultivation of their named double varieties of this Crown Anemone. Nowadays, though these are still obtainable, the popular taste lies in the single Anemones or in the semi-double flowers, so grandly represented by the St. Brigid varieties, which in brilliancy and in intrinsic worth for garden decoration or for cutting are not surpassed. Much might be written on the history of the Crown Anemone and its developments; but the scope of this article will not permit of this, as it is intended to be strictly cultural, so as to afford some information for the beginner in its culture.

Raising from Seeds.—Raising from seeds is a cheap and pleasant method of securing a stock of

to really successful cultivation of the Crown Anemone. When the leaves have withered, the tubers are best lifted and stored either in bags, as previously mentioned, or in dry sand, which is better. Some experience difficulty in discerning the top of the tubers, which should be placed uppermost. These are generally marked by little knobs or protuberances whence the growths spring, but it is generally easy to discover a few of the old roots which have remained on the tubers, and this part should be placed downwards. Where there is any doubt, however, it is safer to plant the tubers sideways.

The double varieties are not now much in request, and they are neither so useful for garden decoration nor for cutting, although very handsome with

NATURALISING DAFFODILS IN GRASS.

With the advent of autumn rains comes the season for planting Daffodils in grass. This is beyond doubt the most beautiful way of growing Daffodils, as the flowers are never seen to greater advantage than when planted in large breaks through an open woodland or in dritts on grassy slopes. It is necessary that the groups should be of irregular outline, with a few scattered here and there to make the grouping as informal and as natural as possible. The illustration on this page gives an excellent idea of the kind of grouping that is desirable. The best effects are produced by planting one variety by itself, such, for instance, as the fine display of Emperor seen in the illustration

COLOURED PLATE. PLATE 1476.

SOME GOOD NEW DAFFODILS

WITH the exception of Utopia, or, as it is now called, Discus, these flowers were all exhibited at the Royal Horticultural Society's Forced Bulb Show on March 18 of the present year. They have no particular connection with one another beyond the fact that they are all first-class flowers in their respective classes. Dream, which is a rather small-sized white Ajax ($\frac{3}{4}$ inches by $1\frac{1}{4}$ inches by 1 inch), is a Dutch seedling, which

DAFFODILS NATURALISED IN GRASS IN AN OLD ORCHARD IN CUMBERLAND.

their almost ball-like heads of bloom. More valuable are the double Chrysanthemum-flowered varieties, which have narrower petals and are more graceful. The ordinary single varieties are very pretty with their cup-like blooms of the most varied colouring; but the most valuable of all are the St. Brigid Anemones, which are not only very robust, but are of the most glorious colours and are generally semi-double. Some splendid strains of the St. Brigid Anemone are in cultivation. It only remains to be added that the colours are most varied. They range from purest white, through blush, rose, pink and scarlet, and from almost lilac to deep blue. For bedding purposes, separate colours can be procured

Dunfrics.

S. ARNOTT.

on page 462. Although some varieties mix well together, the different types do not enter into perfect harmony with one another. Thus the Poets and the trumpets, or the Star Narcissi and Poets, should not be intermingled at planting-time. Among the best varieties for naturalising in grassland or meadows we would place Emperor, Empress, Golden Spur and Horsfieldii as four of the very best. Henry Irving, Queen of Spain and all varieties of Poeticus are specially suitable for woodlands and orchards, also pallidus precox in those districts where it is known to succeed. Barri conspicuus and the old Double Yellow (Telamonus plenus) are both deserving of extended planting in parkland and meadows. All Daffodils, however, may be planted in grass.

C. H.

I imagine was "spotted" as a "good thing" by Mr. Leak some few years ago, for I think I am right in saying that Messrs. Bath have now a nice little stock of it and are ready to supply any orders they may get. It is a drooping flower with a somewhat straight and very refined-looking trumpet, and should make an excellent pot plant. You know, I have a great idea of the value of Daffodils for pots, and those readers who buy the Royal Horticultural Society's Year Book will see that my opinion is there supported by a very *weighty* authority, who shares my belief that for this purpose Daffodils have a "great future" before them. In my part of the world we do not get any blooms in the open until April is well in. March, however, is no longer a non-Daffodil month, for I have a

succession of choice varieties indoors, coming on one after the other, even before February has run its course.

Florence Pearson is now getting fairly well known. I call my friend Duncan Pearson a very lucky man. I wonder if any of us raisers have got such a proportion of first-rate varieties from the seed he has sown as he has; e.g., Lowdham Beauty, Elfrida Pearson, Hon. Mrs. Francklin, &c. Readers know my views about the future of this fine plant for the garden. When Florence Pearson is lower in price, it will be the Mme. de Graaff of to-day, and that splendid variety will have to suffer a partial if not a total eclipse. The Doctor is one of my own importations from the Land of Bulbs. It has not the circular perianth which many of our stricter judges still swear by, for the segments take a star-shaped form. Nevertheless, it is a

as I do Ethelbert with Arthur Goodwin. "Quite unknowns to himself," I expect, he was the one who first introduced me to its quiet beauty by a description of it which he wrote years ago for THE GARDEN. Cartwright and Goodwin still give it a large space in their catalogue, which is, I take it, the analogous expression of a firm to the individual one of a warm corner in one's heart. In prosaic terms, it is a white-perianthed Barrii, with a rather undulating perianth and a flattish eye of pale citron, margined with a narrow band of reddish orange; breadth of flower, about 2½ inches. Utopia, which now appears in Mr. Christopher Bourne's list as Discus, first saw the light of day at the Birmingham Show of this year. I notice he has classed it as a Barrii (3b), whereas in my "Midland" notes I have got it down as a flat-eyed Leedsii, with broad and overlapping segments and a large flat eye, green in the centre, but other-

WHAT IS A FLORIST'S FLOWER?

I HAVE just finished reading a little book, "Daffodils," written by the Rev. J. Jacob, a name sufficiently familiar to those who read THE GARDEN. It is not a very recent book, but it is new to me, and has set me thinking. Not that there is in it anything that will appear novel or startling to experienced Daffodil-growers, the scope of the work being too limited to permit of very exhaustive or original treatment. What there is of it, however, is on sound lines, sufficiently so to lead one to hope that Mr. Jacob may presently see his way to try his hand on a larger canvas, and tell us all that there is to tell about the flower. At the same time, though I agree in the main with Mr. Jacob's ideals, preferences and general views in respect of the Daffodil, I do not invariably find myself in accord; and my object in referring to the little work is not so much to praise it as, with your permission, to touch on a point of subsidiary importance on which I join issue with the author.

My slight and friendly cavil concerns the sixteenth chapter of Mr. Jacob's book, in which he proposes to elevate the Daffodil to the rank of "florist's flower"—for as elevation Mr. Jacob would evidently regard such a change of status, though to some of us this kind of promotion may appear rather in the nature of a "kicking upstairs." Mr. Jacob looks for the coming of a latter-day Glenny to teach us what is, and what is not, desirable in the Daffodil. No doubt the instructions of a Daffodil pope might relieve judges at shows of some trouble and responsibility by rendering their duties as nearly as possible mechanical; but most lovers of the flower (lovers of the Daffodil are not all judges or even exhibitors) will prefer, I should think, to have the Narcissus left outside the group called "florist's flowers," the merits of which have too long been decided by appeal to narrow and sometimes irrational standards. Not that one would wish to belittle the achievements of the professional florist. I for one have no wish to

underrate what he has done for our garden flowers. To that very striving after conventional and arbitrary standards we owe very largely the lovely varieties of Auricula, Carnation, Tulip and other flowers which beautify our beds and borders at the present moment. To be sure, it is doubtful whether the particular features which the florist has insisted upon for his special flower have always added to its beauty. A poet has told us that beauty and truth are convertible terms—"Beauty is truth, truth beauty—that is all we know and all we need to know." I do not know about that.

When we come to plain prose, such generalisations involve a certain amount of juggling with words. Anyhow, where beauty is not a matter of truth, it is purely a matter of taste; and, as we all know, there is no disputing about matters of taste. The point is that the florist, having his own notion of

A WOODLAND SCENE IN SPRING. NOW IS THE TIME TO PLANT THE DAFFODIL BULBS.

good show flower, for there is no "quartering," and the texture is as smooth and refined as anyone could desire. Mr. C. Bourne had a fine example of it on his stand. In the open it is decidedly on the late side. It was the only yellow trumpet that I was able to stage at Birmingham in the abnormal season of 1911. Although smooth and refined, it is a large flower. The measurement of the bloom above referred to was 4½ inches by 2 inches by 2 inches—larger, in fact, than an average Olympia, which is given in Robert Sydenham's book as 4½ inches by 1½ inches by 2 inches. Ethelbert was on his stand. In writing of its singular charm, it makes a lump come in my throat to think that he will never see the sales which it certainly deserves to have; nor yet those of his Tinsel, which I consider in many ways as an improved Ethelbert. I expect I will always associate this lovely variety with "Uncle Robert," just

wise of a beautiful shade of buff. It makes a fine show bloom, but I would like to raise the question: What is a Leedsii, and what is a Barrii? It will be interesting to see where Mr. Rudolf Barr will place his St. Olaf. These two varieties are "much of a muchness" in general appearance, and I am certainly inclined to regard both as Leedsis, of which the Royal Horticultural Society's Classification List gives this definition: "Perianth white, and cup or crown white, cream or citron: embracing all sizes as found in the *Incomparabilis* and *Barrii* classes." The italics are mine. I think we should always bear this part of the definition in mind in pigeon-holing our purchases or our own seedlings. A word of congratulation, in conclusion, to Miss West, the artist, for her very clever grouping. I have only seen her original picture, and it was charming. I hope the coloured print will do it justice.

JOSEPH JACOB.

beauty (his own tastes, in short), desires to impose them, and has largely succeeded in imposing them, upon other people; and so it has been in the past that, by cast-iron standards contrived to this end, the professional florist, while he achieved wonders in certain directions, has prevented the development of flowers from moving with sufficient freedom in certain other directions which are perhaps even more desirable.

Mr. Jacob, like other people, finds definitions to be troublesome things. I certainly should not care to attempt the definition of "archdeacon," but I am not so shy about "florist's flower," which is a much less elusive subject. I should say that when a flower lends itself to infinite variation in the hands of the hybridiser, and, further, has had its standards of excellence definitely determined by experts and generally accepted by growers, it becomes *ipso facto* a "florist's flower." In this sense the Auricula, Tulip and Carnation are florist's flowers. The Lily is not a florist's flower, because neither does it readily lend itself to variation, nor has it been standardised by experts. The Daffodil is, so far, not a florist's flower, because, though it is the most plastic of flowers in the hands of the breeder, it has not yet had its points definitely fixed by authority. The Daffodil, in other words, has not yet had its Glenny, for whose coming, however, Mr. Jacob is not entirely without hope; and when he comes we shall then know what a Daffodil ought to be, and can determine for ourselves the perfect flower by rule and plummet. SOMERSET.

(To be continued.)

NARCISSUS COLLEEN.

It generally happens that among the multiplicity of new varieties of Narcissi exhibited at the Royal Horticultural Society's meetings each spring, one or two varieties stand out from all the rest for their distinct character. So far as my memory serves me, the year 1910 only produced one such variety, viz., Colleen. It was shown by the Rev. G. H. Engleheart and passed into the hands of Messrs. Wallace of Colchester, who placed it before the Narcissus committee, and an award of merit was given. The flower is unique in colour, being of a pure Poeticus white. The cup also is white, with a pure, bright green centre and a narrow edge of green. The whole flower is of great substance, the texture of the perianth partaking more of the Barrii type than the Poeticus; but the general appearance of the flower gives one the idea of a Poet with an enlarged cup, and the usual red colour replaced by green. L. W. G.

A GORGEOUS TULIP.

Now that planting time is here I would advise readers to purchase a few bulbs of *Tulipa fosteriana*. If planted in good soil in a warm spot they should do well, and produce their large, glowing scarlet, goblet-shaped flowers next spring. It is one of the largest Tulips I know, and is always greatly admired in my garden. H

DAFFODILS IN NEW ZEALAND.

THE "Daffodil Notes" and correspondence contributed from time to time to THE GARDEN by the Rev. Joseph Jacob and others are very interesting to us who are following the cult of the spring favourite here at your antipodes, and the coming of them tempts me to pen a few notes about the growing and showing of

plain and swamp, bush-clad ranges and snow-capped mountains, over which is spread a population of just over one million, exclusive of the native Maori. The climate varies from semi-tropical in the North to conditions approximating to those of North Britain in the South, where the winters are frequently severe, with plenty of snow and ice. The country generally enjoys an ample rainfall, and is well watered, anything in the way of drought being very unusual. The four principal centres—Auckland and Wellington (North Island) and Christchurch and Dunedin (South Island)—are

widely separated, though the last two are comparatively near neighbours. It so happens that, although the Narcissus has been grown out here for well over a quarter of a century, and has now attained a strong and increasingly popular position in public estimation, it is only in the principal centres that Daffodil shows of any importance are held, and little or no interchange or competition takes place between different parts of the Dominion (except Christchurch and Dunedin). Thus there is little opportunity for New Zealand growers to compare results and progress, as the Daffodil votary, especially if he be engaged raising seedlings, cannot, during the season, spare the time for the necessary travelling. This particularly affects Auckland, the "farthest North," as the journey from here to Dunedin, for instance, by rail and steamer occupies fully two days of continuous travelling, while the trip by steamer right through occupies five days. Another obstacle in the way of inter-island competition is that our seasons do not synchronise, Auckland being four to six weeks in advance of the South, and by the time Christchurch and Dunedin are holding their Daffodil shows, our horticulturists are concentrating their attention on Roses, Sweet Peas and Carnations for the summer exhibitions. Our flower shows are therefore necessarily of a rather parochial nature, and the gathering of exhibits and the friendly intercourse and rivalry of enthusiasts from all parts, which make so largely for the success of English shows, are denied us here.

Having said so much on general conditions, I will now try to deal with Daffodils in this (Auckland) district, and as I have been a grower of them for over twenty years, and have been an active promoter of the spring show of the Auckland Horticultural Society for a large part of that time, I am fairly well acquainted with the subject. The Auckland district offers growers a large choice of soils, from very light volcanic (the Auckland isthmus is a nest of extinct volcanic cones) to the stiffest clay, and also varied aspects, and the climate, being mild, with ample rainfall during winter and spring, while heavy frosts are very rare, is eminently suitable for the cultivation of Daffodils. At the same time, these conditions necessitate a ceaseless warfare with weeds, slugs and snails throughout the season, which they also serve to lengthen much beyond what, I understand, you are accustomed to. It is not unusual to have the Paper White and other Polyanthus kinds in flower in May, early trumpets following towards the end of

NARCISSUS COLLEEN, A BEAUTIFUL NEW VARIETY WITH A LARGE EYE OR CUP.

the "Daff" out here, in the hope that you may find something among them of interest to your readers in the Homeland.

A few words first as to the geographical and climatic conditions in New Zealand may not be out of place; for notwithstanding the way this Dominion has of late years been "boomed" at home, and the large and increasing number of English people who annually visit us, I am afraid that, to the bulk of the great British public, we are *terra incognita* still. New Zealand is over one thousand miles long from North to South, with an area of over one hundred thousand square miles of

June; from then onwards they come in increasing numbers till the flush of the season in September, after which time they gradually thin out, though late varieties may some seasons be cut up to the middle of November. I speak here of outdoor culture only, as practically nothing is done in this district in the way of forcing, except perhaps when one wishes to have for exhibition some variety which usually flowers too late outside.

Most of our growers regularly import the newer varieties from English firms; but, as we have no wealthy leisured class, we have to wait till the prices come within reasonable limits, though some varieties priced at £10 a bulb and over have been imported; and several devotees cultivate collections of from 100 to 300 or even more varieties. Our principal spring show, under the auspices of the Auckland Horticultural Society, is held in the first week of September, and is undoubtedly the most popular show of the year, coming as it does to tell us winter is past; for even in this favoured clime flowers are at times very scarce during the winter months. Competition is usually good, the schedule providing opportunity for all growers, classes ranging from single blooms to stands of forty varieties. As before explained, the exhibition is apt to be rather local, a radius of fifteen miles covering all exhibitors, with one or two exceptions. Recently two inland towns—Hamilton and Cambridge (80 and 100 miles South)—have instituted regular spring shows, and some exchange with Auckland has taken place, while three other provincial towns—Thames, Rotorua (celebrated for its thermal wonders) and Clevedon—also made a move last season. The fancy is as yet in its infancy in these places; but Cambridge possesses a large grower in Mr. W. F. Buckland, who is also a most successful Chrysanthemum man, known beyond New Zealand as the raiser of some sterling new varieties of that flower.

In the matter of producing new Daffodils, Auckland promises well. Probably our oldest and most successful grower is Professor A. P. W. Thomas of Auckland University, and in the fascinating hobby of raising Daffodil seedlings he is *facile princeps*. He was the first to take up the Narcissus in this district, and was quietly working away at it long before most of us knew anything better than Emperor or Empress. Now, his beautiful grounds with walled terraces, flower-beds, rockeries and winding paths formed with much labour out of the rough scoria slopes at the foot of Mount Eden—an extinct volcanic cone in the suburbs—contain, besides many imported Narcissus aristocrats, a very large number of beautiful new varieties, the result of his systematic and careful hybridising and culture for many years past. Could the pick of

these be grown as he grows them (for there is a lot in the growing), and staged at Birmingham or other of the English shows, I feel satisfied they would not lack attention and appreciation from the connoisseurs. Among his earlier productions are many fine yellow trumpets of *maximus* and M. J. Berkeley type, and large, tall-growing incomparabilis; but among his later seedlings are many fine, "cool"-looking flowers, both trumpets and cups, including some very taking Johnstone hybrids. Among the latter are some of the most floriferous plants I have seen, some bulbs sending up as many as four or five stalks, carrying from two to five large flowers like fair-sized trumpets,

of Daffodils, excluding Polyanthus), thereby winning outright the society's handsome silver vase. Last season he showed only in classes for single blooms (winning in eight out of nine classes, five of the blooms being his own productions) and for seedlings. He also staged for exhibition only a large and handsome group, nearly all of his own raising, and comprising, among others, the varieties commented on by Mr. F. Herbert Chapman in your issue of November 30 last.

Another enthusiast is the Rev. William Beatty, Vicar of St. Mark's, Remuera (a suburb of Auckland), the Daffodil occupying first place in his affections. Some years ago he initiated the "St. Mark's Daffodil At Home" in his Parish Hall, and it has become a successful annual fixture. It takes place usually two or three weeks prior to our principal show, and provides opportunity for a display of the advance guard of yellow trumpets, &c. Mr. Beatty's preference seems to be for the "first-early" section, and these largely preponderate in the Vicarage garden. He has done some hybridising among them, directing his efforts to obtaining "early birds," and though his productions might not attract much attention in competition with modern high-class show blooms, he has several very early yellow trumpets that will be of value in the cut-flower industry when more plentiful.

Aroused to emulation by the success of Professor Thomas, several other growers here have from time to time taken up seedling-raising, and some half-dozen of them have passed through the long patience-trying initial waiting, and there is every indication that before long we shall have competition in classes for "seedlings raised by exhibitor," hitherto monopolised by Professor Thomas. This aspect of Daffodil culture largely influences the choice when importing, and varieties with a reputation as good seeders are preferred, though we find they do not always bear out that character when acclimatised here. I suppose the change of climate and environment disturbs their constitutions to some extent. In the Auckland district the seed germinates well in specially-prepared beds in the open air, and is usually sown just after the first autumn rains, about the end of March and through April. I notice some of the authorities at home recommend sowing the seed as soon as ripe (that would be October and November here), but those who have tried this here have found no special advantage to accrue, and think the seed is safer kept until autumn than lying in the seed-bed well baked by our hot summer sun.

Auckland, New Zealand. A. E. GRINDROP.

(To be continued.)

A BEAUTIFUL BOWL OF TULIPS PRINCE DE LIGNE. THESE HAVE BEEN GROWN IN FIBRE AS DESCRIBED ON THE OPPOSITE PAGE.

varying from pure white through shades of yellow. Although his soil is the light, loose material of the volcanic parts, a very noticeable feature is the strong growth and height usually attained, many of the trumpets and medios averaging 24 inches to the ovary, some varieties measuring as much as 30 inches, while one kind, aptly called Flagstaff, exceeds that height.

Owing largely to the quality of his own seedlings, Professor Thomas secured first place at our spring shows in the consecutive seasons of 1909-10-11, against strong competition with imported varieties, in the largest class (forty varieties

GARDENING FOR BEGINNERS.

GROWING BULBS IN FIBRE.

AS each September comes round, my thoughts turn unerringly to the culture of spring bulbs for window or room decoration. Hyacinths, Narcissi, Tulips and Crocuses are my favourites, and I grow all of them in bowls filled with fibre; the latter, specially prepared for the purpose and sold as carbonated fibre, may be obtained from almost any firm of nurserymen, and it is quite inexpensive. Moreover, it is clean to handle and is not offensive indoors. Almost any bowl that will accommodate the bulbs will answer, although the best kind I know is the "Oriental," supplied by Messrs. Hunter and Gow, Limited, 36, Thomas Street, Liverpool. This bowl contains an inner bowl with holes in the bottom,

down on the surface, the growing bulbs may be unable to thrust their way through, with the result that the whole of the top fibre may be litted right up above the bowl. Again, space should be left at the top of the bowl—about half an inch or so—to allow for watering. The very rough parts of the fibre should be rubbed out, and a few pieces of charcoal placed in the bottom of each bowl.

After Potting, very little attention will be needed for at least three weeks. The fibre should

be kept just moist—not sodden on any account, or this may lead to the early decay of the bulbs. Keep the bowls in an

airy cellar or room; nothing is worse than confining them in a cupboard. After a few weeks, growth will commence, and when this is about one inch high the bowls may be brought to the light. From this period onwards the bulbs require more moisture to supply the growing tissues of the plants. When removed to the light, let the bowls be placed in a cool greenhouse, frame or on a window-sill; but on no account must frost be allowed to reach them.

Selection of Varieties.—Of Hyacinths one cannot do better than

grow such standard varieties as Grand Maître (pale blue), L'Innocence (pure white) and Moreno (pink). Most of the Crocuses can be relied upon, but I have found *purpurea grandiflora* (purple), King of Whites and Queen of Sheba (yellow) a grand trio. Tulips are not always a success with me, although Prince de Ligne (yellow—see illustration on opposite page), Cottage Maid (pale pink) and Keizerskroon (crimson and gold) are among the most satisfactory I have tried. Mon Tresor is a fine early yellow Tulip, and Scarlet Van Thol is certainly worth growing, as it is extra early and of very light colour. Of Narcissi, the following are to be relied upon for growing in fibre: *N. obvallaris*, the Tenby

A FINE BOWL OF YELLOW CROCUSES. THESE ARE AMONG THE MOST SATISFACTORY OF ALL FLOWERS FOR GROWING IN BOWLS OF FIBRE.

Daffodil (one of the first to flower), Golden Spur, Emperor, Horsfieldii or Empress, and Porticus ornatus. SPARTAN.

POTTING AND BOXING LOBELIA.

CULTIVATORS sometimes lift and pot whole plants direct from the flower border. Very often they die before Christmas. Plants that were duly prepared by cutting back for the supply of cuttings are the best to lift and pot now; but every plant should be carefully divided, the parts being inserted round the sides of 6-inch flower-pots filled with a light and sandy compost. Whether in frames or in houses, the plants must not be subjected to a dry heat, but be very carefully watered and guarded against excessive atmospheric moisture. B.

A BOWL OF ROMAN HYACINTHS IN COURSE OF POTTING UP. THE BULBS SHOULD BE ALMOST COVERED WITH FIBRE, THE SURFACE OF WHICH SHOULD BE HALF AN INCH OR MORE FROM THE TOP OF THE BOWL.

which allows water to drain into the outer bowl without disturbing the bulbs. However, ordinary bowls without drainage answer very well, providing that over-watering is guarded against. I find it best to grow one variety only in a bowl, although there is nothing to prevent one mixing varieties or even different kinds, such as Hyacinths over a groundwork of Crocuses. When one variety only is used to a bowl, the flowers may be relied upon to throw their spikes of bloom uniformly and at the same time; but this is not so when they are mixed.

Above all it is necessary to purchase bulbs from a reliable source. The best bulbs only should be used, and the writer has known of many failures through purchasing cheap bulbs late in the season. Small bulbs or corms, such as in the case of the Crocus, should be covered with about their own depth of fibre, but large bulbs, such as Hyacinths and Daffodils, need not be completely covered. The fibre should be moist at the time of potting up, but not saturated. It should be pressed fairly firmly around the bulbs. If pressed hard

HYACINTH GRAND MAITRE PLACED IN A BOWL OF FIBRE. ONLY THE VERY BEST BULBS SHOULD BE SELECTED FOR THIS PURPOSE.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Fuchsias.—These should be propagated now, selecting, as far as possible, the young growing shoots that are not carrying flower. Put seven or eight cuttings round the side of a 4½-inch pot, from which they may be transferred into single pots as soon as nicely rooted.

Propagation.—The work of propagating soft-wooded bedding plants must be proceeded with at once, and if suitable accommodation is provided, such plants as *Coleus*, *Iresine*, *Alternanthera*, *Alyssum*, *Mesembryanthemum*, *Heliotrope* and *Ageratum* will root as quickly now as at any time. Where plenty of propagating-cases with bottom-heat are at liberty, these may be utilised, but, failing these, it is wise to make up a moderately good hot-bed to take as many low frames as may be required for the cuttings, plunging the pots to the rim in Coconut fibre.

Abutilon Thompsonii should be treated similarly to *Fuchsias*, but should be given a size larger pot when potting off, and to make really good specimens must be kept growing gently throughout the winter.

Flower-Beds.—These must be kept regularly picked over, so that they present a tidy appearance as long as possible. Any beds that are quite gone over should be filled up, where the convenience allows of it, with such subjects as early-flowering *Chrysanthemums*, *Salvia splendens*, or even dwarf-growing *Asters*, these, of course, having been specially prepared. If in pots there will be very little trouble, except that the watering must be well attended to; but if lifted from nursery beds or borders the syringe will need to be kept going should the weather be hot and dry after shifting. The *Lobelias* are quite over in some districts, and these must be pulled up. If the other occupants of the beds have grown well, they will not be much missed at this season.

Plants Under Glass.

Coleus should now be propagated for stock purposes, and if put in single pots may be potted on as they are, and so form nice plants quite early. For providing cuttings for the spring, three may be put in a 3-inch pot. I make a practice of putting in more than is actually required for stock, the surplus being used in the autumn for edging small groups, or as groundwork, with small Ferns, for decorative exhibits of *Chrysanthemums*.

Small Decorative Subjects, such as *Selagmellas*, *Panicum*, *Fittouias* and *Tradescantias*, should also be propagated in quantity, sufficient pots being made up to last through the winter; and where large parties are given during the shooting season it is astonishing how many pots of small stuff are required.

Bouvardias and Solanums that may have been planted in the open ground or in frames should be lifted and potted at once. Considerable care will be necessary to get them over the shift without a severe check, but by careful syringing and shading for a few days and keeping the house or frame quite close they will soon begin to make fresh roots, when they may be given more air and light.

Perpetual-flowering Carnations.—If the house or houses are not already prepared for the reception of these plants, they should be cleaned at once, so as to get the plants in without delay. They should be carefully tied, and well sprayed to make quite sure that they are free of spider or any other insect pests at the time of housing. I find sulphide of potassium a really good thing to syringe with, but the plants must be allowed to dry before being taken in, or the solution is apt to mark the paint where it comes in contact with it.

The Kitchen Garden.

Spinach sown a few weeks ago should now be advanced enough for thinning. If thinned to about three inches apart now, it may be again thinned, taking out every alternate plant when large enough to use, and the remaining plants should stand the winter well. Sprinkle the ground about them well with soot during showery weather; this will keep the plants healthy as well as keep down slugs.

Lettuce should now be sown on a warm border where it will stand the winter, *Hardy White Cos* and *Stanstead Park* being two varieties as well suited for the purpose as any.

Endive.—The latest batches of this should be pricked out, choosing a warm border where lights may be placed over the plants in the event of very wet or severe weather later in the season. Early batches that are nearly fit for use should be tied up for blanching, choosing a time when the foliage is quite dry, or they may be inclined to damp or rot off.

Cauliflowers should now be sown for spring planting, choosing a position on a warm border where the soil is fairly light and well drained. In some localities they may stand in the open air, but in most places they will have to be pricked out in frames or under hand-lights to come through the winter successfully. Early *London* and *Walcheren* are the two varieties that do best in this neighbourhood, the former, if anything, being the best of the two.

Hardy Fruit.

Fruit Gathering.—Owing to the drought I find many varieties of both Apples and Pears maturing earlier than usual, so that a sharp look-out must be kept on the trees to prevent many of the fruits falling. The different varieties should be gone over once or twice a week, gathering those that show signs of falling off, and storing them as thinly as possible in the fruit-room. Extra good specimens that it may be desirable to leave on the trees should have bags placed over them; but I have noticed a decided tendency on the part of Pears that have been bagged to go sleepy much more quickly than those not so treated; this, no doubt, is due to the want of air to the fruits during the maturing period.

Strawberries.—Good, firm planting is quite necessary, and where the roots have become matted in the balls of soil they should be eased out somewhat. In the event of continued drought the plants must be kept watered until they show signs of having got a good hold of the soil.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)
Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Planting Border Pinks.—Cuttings or pipings inserted in the summer will now be ready for planting out. If they are to occupy a separate border or bed, they should be transferred to their flowering quarters forthwith. If, on the other hand, they are to be planted near the front of mixed beds or borders, they may be run out into nursery lines now, and transferred to their flowering quarters after the beds and borders have been dug over in spring. Pinks succeed best in a medium or light soil, and no rank manure should come in contact with their roots. *Mrs. Sinkins* and *Her Majesty* are fine for edgings or growing in masses. The old laced varieties are very beautiful, and *Napoleon III.* should not be overlooked. Many of the single seedlings are also very beautiful, both in form and colour.

Herbaceous Plants.—See that *Asters*, *Golden Rods*, tall *Helianthus* and such like are proof against the autumn winds. Cut over the flower-stems of all plants as they go out of bloom, and as the natural beauty begins to wane, try to make the garden as attractive as possible by keeping everything trim and tidy.

The Rose Garden.

Selections for Planting.—I now give a few names for the benefit of beginners who may contemplate planting this November. Where a mass of bloom is the chief aim, the following can be heartily recommended: *Reds*—*Hugh Dickson*, *J. B. Clark* (both very vigorous), *Captain Hayward*, *General Macarthur*, *Richmond* and the old Hybrid *Perpetual General Jacqueminot*. *Pinks*—*Caroline Testout* (a vigorous grower and perpetual bloomer), *La France*, *Mme. Abel Chatenay*, *Mme. Jules Grolez*, *Mrs. W. J. Grant*, and the two old Hybrid *Perpetuals* *Merveille de Lyon* and *Mrs. J. Laing*. *Yellows*—*Mme. Ravary*, *Le Progrès* and *Gustave*

Regis. *Whites*—*Frau Karl Druschki*, *Augustine Guinoisseau* and *Amateur Teyssier*. For general purposes the following are all excellent, and for descriptions readers should consult a descriptive catalogue: *Antoine Rivoire*, *Avoca*, *Betty*, *Coralina*, *Edu Meyer*, *Edward Mawley*, *Killarney*, *La Tosca*, *Lady Battersea*, *Laurent Carle*, *Liberty*, *Lieutenant Chaire*, *Lyon Rose*, *Mme. Melanie Soupert*, *Marquise de Sinety*, *Pharisæer*, *Prince de Bulgarie*, *Viscountess Folkestone*, *Juliet* and *Lady Hillingdon*, which does well here. The foregoing I know well, but they are only a few among the many.

Pruning Ramblers.—If there is a sufficiency of young, vigorous shoots, cut away all the old wood; if not, retain a portion of it. Of course, more of the old wood can be retained on screen fences and pergolas than on arches and pillars.

The Wild Garden.

General Work.—A general clean up should now be given here. The grass, if gone over with the scythe, will not cause trouble again this season. Many subjects have now gone out of bloom, and their flower-stems should be cut over. *Wichuraiana* *Roses*, too, should have a portion of the old wood thinned out to enable the young shoots to ripen. *Rosa rugosa* in variety is showing the brightness of its hips, and the *Dogwood* leaves are growing beautiful in decay, to be succeeded during the winter by the beauty of their bright bark. Where these plants are absent, they should be planted before another season.

The Pleasure Grounds.

Lawns.—Grass is failing more quickly than usual this season owing to the drought; still, the mower should be kept going till October is well in, as a few tufts, even here and there, if left cause the whole lawn to look unsightly. If wormcasts appear, the *Birch broom* should be brought into play, followed by the roller.

Leaves.—These are now causing trouble, and should be cleaned up once a week or oftener, according to circumstances. If skilfully handled, nothing equals a new *Birch broom* for this work, especially on grass or smooth walks and drives.

Pruning Hedges.—If not already done, this work should be carried through at once, for two reasons, viz., the wood is so much softer now than later on, and if *Privet* (evergreen) is cut later it remains bare all the winter.

Plants Under Glass.

Chrysanthemums.—The operation of taking the bud will now be well over, but attention must still be given to the work where necessary. Disbudding the terminals will now claim attention in the decorative section. The extent to which the process should be carried must depend upon the natural size of the flowers. Among the singles, for instance, varieties like *Ladysmith* and *Kitty Bourne* require no disbudding, whereas the *Pagrams* and others of large size should have at least half of the buds removed.

Caladiums as they go to rest should be stored away on their sides where the temperature does not fall below 60° during the winter.

Fruits Under Glass.

Pruning Early Vines.—As soon as the occupants of the early house have shed their foliage, they should be pruned. A sharp knife is much preferable to the secateurs for this work. Cut well back, as only one bud is required for each spur; and while it is true that surplus buds can be rubbed out in spring, a succession of long spurs soon handicaps the tree in the production of good fruit.

The Vegetable Garden.

Earthing-Up Leeks.—It is only the blanched part of a Leek that counts; therefore the more blanched portion the better. If planted in trenches, earthing-up is done in the same way as *Celery* is treated; if grown in lines, the Leeks being planted in the bottom of drills as I advocated at planting-time, the ground will now be level and a good portion of the plants blanched. This can now be increased by giving the plants an earth-up with the draw hoe in the same way as *Potatoes* are treated.

Brussels Sprouts.—If the plants have all the decayed and semi-decayed leaves removed, the sprouts will develop all the better.

CHARLES COMFORT,
Broomfield Gardens, Davidson's Mans, Midlothian.

"THE DAFFODIL YEAR-BOOK."

THIS admirable little book is a landmark in the history of the Daffodil, a witness to its attainment to a probably permanent state of equilibrium after the many ups and downs of its long history.

Old John Parkinson, born in 1567, is usually quoted as its authentic father in English gardens—he grew or knew nearly a hundred kinds—but we learn from Turner, born twenty years earlier, that before Parkinson's time "Narcissus" was "of diverse sortes," and we may believe that some daffodil or another was to be found in English gardens almost from their first beginning. Gardening, with most other arts, was a good deal obscured in the drab stretch of the eighteenth century, but our flower reasserted itself strongly from about 1830 onwards, and thence-forward the stages of its progress are visible enough. Haworth had nearly completed his classification, still the basis of our own, at the last-mentioned date, and by 1840 the cross-breeders had broken into a new world. Herbert, Leeds, Backhouse and Barr carry us link by link to our present crowd of producers and products.

It is a far cry from the "white Daffodil" that was growing "plenteously in my Lorde's Gardine in Syon" in 1548 to the bewildering multiplicity of blossom in a 1913 Vincent Square Show. But always throughout these centuries the Daffodil has been a—we may perhaps say the—distinctively English flower, cherished and developed exclusively by English hearts, brains and hands. And its permanence is witnessed to by the book now under notice. There was a period in our recollection when the Daffodil seemed to fall into the paraphernalia of the new medieval aesthetes, and John Bull was inclined to laugh at its "cult" as a transient craze of poets and parsons. But the spring-hunger for flowers is eternal, and this flower's intrinsic beauties and possibilities have safeguarded it against both petting and ridicule, while, best insurance of all, our flower-markets demonstrate its solid commercial position. And a flower has surely come to stay when, after some 350 years of its life, the Council and President of the world's greatest horticultural society make such a book a part of their serious output, and can speak (page 80) of the "greatly increased interest taken in Daffodils." The Daffodil contraternity—a phrase now out of date, for it is fast becoming synonymous with the flower-loving public—should be grateful to the Society for such a helpful publication, and to its Editor, the Rev. Joseph Jacob, who has made it a labour of love, and has gathered and arranged his material with great skill.

The book leaves little to be desired, either outwardly or inwardly. Its strong canvas binding of quiet daffodil green is in excellent taste; it lies open well—how many books provoke hasty language by the contrary defect!—and has the best of paper and type. The contents have been so contrived as to be valuable alike to the most advanced expert and to the most tentative beginner.

The dry but quite necessary official and statistical information about the London and provincial Daffodil societies and shows, with their awards, the standard classification of Narcissi for exhibition, the Royal Horticultural Society's schedule and entry form for 1914, &c., is given minutely and clearly, and is enlivened by instructive articles on hybridising, the preservation of show blooms, the novelties of 1913 with illustrations, and the pot cultivation of Daffodils. The pages on some of the "Celebrities of Daffodildom" are faced by portraits quite surprisingly well reproduced. Those who had the privilege of knowing Mr. Peter Barr will see the man himself *redivivus* in this aggressive-looking but most characteristic presentment. Mr. Andrew Kingsmill's face, too, recalls the earlier daffodil days. Alas! the flower endures, but its votaries pass.

There is place for little adverse criticism. Possibly the tables of dates of opening of specified varieties are of small practical value. Localities have each their own climate, and seasons vary so

are concerned with its subject. They have no desire to make profit by the undertaking, but they consider that any such publication devoted to the interests of one particular flower should come within reasonable distance of proving self-supporting." Surely such support will be abundantly given. The price (7s. 6d.) is almost ridiculously small for such a book. G. H. ENGLEHEART.

COSSINGTON HOUSE.

THE CROSFIELDS AND THEIR DAFFODILS.

LADIES first, please! I cannot write Crosfield in the singular, for surely no lover and exhibitor of flowers has ever had a wife that backed him up better and encouraged him more—not only by precept, but by example—than Ernest Crosfield. The good man is busy or away; she is his eyes, and goes carefully round

THE BEAUTIFUL GROUP OF DAFFODILS EXHIBITED BY MESSRS. JAMES CARTER AND CO. AT THE LONDON SHOW IN APRIL THIS YEAR.

irregularly that it would take a century to establish that somewhat delusive thing an average. It may be pointed out that black-and-white illustrations of yellow flowers are not at all informative to the eye. Thus the entire value of Jonquilla-hybrid Marigold (Fig. 2) lies in its peculiarly rich quality of yellow, whereas the figure suggests nothing but a rather weak white Ajax. On the contrary, the frontispiece, in colour, of the two remarkable red-perianthed seedlings is a faithful and intelligible portrait. The present writer, by the way, has had more than one of such newcomers in his own seedling-beds, and has neither admiration nor use for them. A chief glory of the Daffodil lies in its classical restraint and delicacy of form and colour, and a wholly red flower would fall outside such bounds.

In a prefatory note the President and Council of the Royal Horticultural Society explain that the annual continuance of this valuable issue must depend upon the support given by those who

the beds marking what he ought to see when he returns or is free. The bustling time of putting the blooms into their travelling boxes has arrived. She is always packer-in-chief at home, and a jolly good one, too, for "E. M." writes "as far as I know we never have had a single bloom damaged." What her sister and herself do when the show rendezvous is reached, every exhibitor and competitor at London and Birmingham knows full well. And what of 1911? When *he* thought the cupboard bare of prize-winners, did not *she* go into the drawing-room and the garden, and "on her own" get together a fine exhibit which secured her a place on the honour roll of winners of the Bourne Cup? Bravo! Mrs. Crosfield. May your sporting example never be forgotten! We none of us know what we can do until we try.

Cossington House is a comfortable country residence about four miles from the town of Bridgewater. When circumstances necessitated a move

from 1880. Acton, near Wrexham in 1880, it was very largely chosen because it was thought that the soil would be particularly suitable for Daffodil culture. Imagine, then, Mr. Crosfield's feelings when he found that it was by no means the ideal ground that he had taken it to be. It was a crushing blow, and some men might have given up in disgust. Not so the subject of my sketch. With that dogged determination to succeed which has placed him among the very best shots and the very best fishermen of his day, he began to look about to see what could be done. He was fortunate in being able to secure some wonderfully good land about four miles on the coast side of Bridgwater. And then to make his own garden, in part at any rate, suitable, at immense cost he carted sand and some of this good soil to Cossington, so that as this operation is more or less a yearly one, he has a gradually enlarging patch to which he feels safe in committing his most cherished bulbs, such as Gyrfalton, Wilonyx and Aladdin. I have twice been privileged to pay a visit here in the busy month of April. I call it to myself a "tuning up." From a show point of view I always say that Mr. Crosfield's judgment is "concert pitch." Texture and refinement come first with him—then colour and size. This is why he thinks so much of Wilonyx, a very smooth and very refined Giant Leedsii (4 inches by 1½ inches by 1 inch), and Aladdin, an exquisite bicolor incomparabilis, equally chaste (4 inches by 1½ inches by 1 inch). They are, he tells you, precursors of a new type, which in time is destined to monopolise the show-board. Remembering how lengthy has been the evolution of the Tulip, he is probably right. Many of the flowers of to-day will be to the flowers of the future what Crosfield's exhibit of fifty at Birmingham in 1902 is to his winning collection in Class 1 in London in 1913.

How well I remember that time! It is for me an oasis in the past. I actually beat him then, Jacob was placed fourth and Crosfield fifth. When I look back and think of it, I feel as if I had had the distinction of bowling Grace. Since then how he has gone ahead! Full speed! His first Daffodil seeds were sown in 1808, when he lived at Lynton in Cheshire. There were 127 in all, of which ninety were Mme. de Graaft and Weardale, crossed both ways. When he moved to Wrexham in 1809, these were, naturally, taken great care of, and in due course bloomed, with results which must have surprised him at the time, and which probably do even more so now he can look back on them with accumulated experience. The very first to bloom was the beautiful Countess of Stamford, to be followed later on by Banzai, Lolah, Indamora, Catrona, Maud Marian, Mrs. Ernest Crosfield and Herod, a truly marvellous lot to come from a first attempt. Times have changed since then. In the fifteen years that have elapsed, Mr. Crosfield has given us many magnificent flowers.

One gets to know what the public likes best, but I am always curious to know what a raiser thinks his best. Here, then, is Mr. Crosfield's list: Five crosses—Gyrfalton, a splendid Giant Leedsii, having height of stem, size and regularity of flower, and robustness of constitution all combined. The white of the perianth has a distinctly green tinge when compared with others. Measurement, 4½ inches by 1½ inches by a quarter of an inch. Four crosses—Premier, Her Ladyship and Elite. Had I been the raiser, Premier would have changed places with Gyrfalton. That wonderful

pair of superb giant incomparabilis acted as a headstone all the time of my visit. Again and again I found myself there looking at the shapely yellow blooms. The large cup is a deep pure yellow, and the perianth, which is very smooth and overlapping, of a paler shade. I put my rule over an average-sized flower, and found it was 4½ inches by 1½ inches by 1½ inches. Her Ladyship is a Giant Leedsii, and Elite a "much larger and a much better Susan." Three crosses—Empire, Challenger, Touchstone, Imperial, Charles Surface, Coquette, King Dove, Mowgh and Orb. I cannot remember having seen Coquette exhibited, but all the others, with the exception of Imperial, have appeared in public. Imperial marks Crosfield's high-water mark in yellow trumpets; 4½ inches by 1½ inches by 1½ inches. At its best it will take a lot of beating. Two crosses—Pixie, Turret, Anchorite and Phantasy. While I am on the subject of records, it will be of interest if I give the names of the fifty exhibited at Birmingham in 1902, which date and occasion mark the entrance of my good friend into the competitive life of the Daffodil fraternity—Emperor, Katherine Spurrell, Sir Watkin, Mincie, Plump, M. J. Berkeley, J. B. M. Camm, Horsfield, Sampson, Goliath, Minnie Minnie, W. Wilks, Mincie de Graaft, Glory of Leiden, Dorothy Yorke, Gem, General Murray, Mrs. Walter Ware, Shakespeare, Mrs. J. B. M. Camm, Ahura, Lucifer, Nelson major, Weardale, Barri conspicuus, Beatrice, John Bam, Scarsion, Beatrice Heseltine, Princess Mary, Citron, Crown Prince, Commodore, Mrs. M. Crosfield, Flora Wilson, Beauty, William Goldring, Waterwitch, Frank Miles, J. Davidson, Peach, Stella superba, Victoria, Nelson aurantius, Mrs. Langtry, Autocrat, Princess of Wales, C. W. Cowan, W. P. Milner, Prince George and Duchess of Westminster. Good flowers still many of them, but not one quite good enough for him to stage now. *Tempus edax senium*.

Now for a bit about the internal economy of Cossington at Daffodil-time. The actual work of conveying the pollen from one flower to another is done by Tomlinson, the head-gardener. He works to a plan, which has been carefully prepared by Mr. Crosfield the previous summer. If such a list were not made, it would be impossible to know what bulbs of late varieties to pot up so as to have the pollen ready for the early-flowering seed parents; and, secondly, by it he is able to avoid repeating altogether the crosses of one season the next. The cutting for show is always done by Mr. Crosfield himself. From that moment until they are safely landed on the show stage he watches over each flower with unremitting attention. The little upstairs room in the outhouse is constantly visited, the light is adjusted as frequently as circumstances require it, and the proper degree of humidity kept up. Every now and again some are brought into the drawing-room to get a stronger light or greater warmth. Once when I was there a sudden fall in the temperature occurred. "In a jiffy" every one of us was as busy as a bee conveying the precious vases to the genial warmth of the linen-room, where they were examined in detail by Mrs. Crosfield and her sister and dealt with accordingly. It showed me the pains that are, and must be, taken to get together a good collection of blooms for the show day. I do not think anyone can beat "E. M." as a preparer for show. He seems to know instinctively what to do with each variety, but it is really the knowledge born of observation and practice, for like an experienced runner who

knows himself, and never slackens until the tape is breasted, he gets all he can out of each individual flower. A last reference must be to the drawing-room. What it is at other times I know not, but in April it is a regular Daffodil bower. The blooms are here, there and everywhere. Vases of the very choicest varieties cheek by jowl with more ordinary ones. A Tom Tiddler's ground, whence the Bourne Cup blooms of 1911 came. Such a wealth of flowers that no Tulip, least of a Turkish Sultan, can have been more glorious. Plenty to look at for hours if the day should be wet. It is a reflection, or rather an April embodiment, of the spirits of the two genui of the place in their busy spring season, for, like the drawing-room, they are "all Daffodils" then, whatever they may be during the remaining twelve months. JOSTIN JACOB.

REGISTRATION OF NEW PLANTS.

In conformity with the decisions arrived at by the International Congress of the International Union of Professional Horticulturists, which met at Luxemburg in 1911, in London in 1912 and at Ghent in 1913, a bureau for the registration of new plants has been formed, to commence in the summer of 1913, under the management of the general secretary of the Union. This bureau is formed for the purpose of making an official list (origin, classification and description) of new varieties of all kinds of plants, and to establish a right of priority, according to the dates of demand for registry given by the growers themselves. The raisers of new varieties of plants should therefore address the list of their novelties for the term 1913-14 to M. van Lemep, Secrétaire Général de l'Union Horticole Professionnelle Internationale, 15 Molenstraat, The Hague, Holland, who will acknowledge reception according to the order of their arrival, and state the number under which the new varieties are entered in the official register.

In order to make the descriptions simple and precise, and after the experience gained by the attempt of last year, it has been resolved that the descriptions shall not exceed three lines. The exact name of the species to which the novelty belongs should be mentioned, as well as the section of the species in which it is to be found. For example, if it refers to a Rose tree, give (1) the words "Rose tree"; (2) if it refers to a hybrid of the Tea Rose, write the words "Tea Hybrid" (or a suitable abbreviation) before the name of the new variety. Proceed in the same way with all other species. If possible, give the description in three languages—French, English and German—each description not to exceed three lines. If the grower himself does not give the translations, the general secretary will not be obliged to do the same. For this first year a registration fee of two francs only has been fixed for each new variety, with the right of (1) being entered in order on the Register; (2) being transcribed on the Bulletin of the U.I.P.I.; (3) to the probable publication by the professional horticultural organs belonging to affiliated associations after their publication in the Bulletin of the Union. For the following term of 1914-15 supplementary charges will be fixed for the work occasioned by the last two reports following the decision that will be taken by the next Congress.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Potatoes Free From Disease.—In the monthly report just issued by the Board of Agriculture, mention is made of the fact that Potatoes are remarkably free from disease this year. This is no doubt due to the dry weather that was experienced during July, when damp conditions, occasioned by thundery weather, usually prevail. Owing to the drought, the tubers generally are small, and the yield is likely to be below the average.

The Cornish Heath (Erica vagans).—This delightful Heath, abundant on the moors of Cornwall, is now flowering to perfection in many gardens where Heaths are treasured. It forms a neat bush less than a foot in height, which at this season is covered with purplish red flowers. There is a white form of the Cornish Heath which is quite as showy as the type, and both are admirably suited for massing in those gardens where Heather and other peat-loving subjects are known to thrive.

Rudbeckias or Cone-Flowers.—At the present time many herbaceous borders are gay with these flowers. There are the annual ones in their golden and brown hues, of which Rudbeckia amplexicaulis, R. bicolor superba, R. b. Solfataria and R. Drummondii are some of the best. Then, among the perennial ones we have R. Newmanii, R. laciniatus flore pleno and R. Herbstsonne. The last named is without doubt the best of them all. Its large, bright yellow flowers are borne on stems 5 feet to 6 feet high above the dark green foliage, and it is in every way a very desirable plant for the flower garden.

Rose Aimee Vibert.—There are not many varieties of Roses that flower more freely or are more serviceable in a garden than this one. Plants look well on arches and pillars, as well as on walls. If properly trained at first, it soon forms a grand bush in the open parts of the garden, and looks charming when pegged down in borders near paths. It is a very hardy variety. One large specimen we know withstood very severe frosts for nearly twenty years in the North Midlands without being damaged and without any protection being afforded. The large white flowers, very pure, are borne in clusters, and are shown to great advantage by their setting of deep green leaves, which remain on the branches a long time.

Planting Fritillaries.—Some of the Fritillaries may perhaps be classed among the plants that are looked upon as more curious than beautiful. At the same time, the well-known Crown Imperial (Fritillaria imperialis) is one of the best of our garden plants, and is excellent for the shrubbery or on the margins of beds of shrubs. The dwarfier ones from Asia Minor, such as F. citrina, F. Whittallii, F. aurea, F. armena and others, are excellent for the rock garden. The Snake's-

head (F. Meleagris), which is occasionally found wild in this country, and its varieties are ideal subjects for naturalising in grass, and give a very charming effect with their mottled, drooping flowers. Bulbs of all should be planted now.

A Valuable Viola.—What a charming, free-flowering plant is Viola Papilio, bearing in great profusion the whole summer through its beautiful flowers, which are of various shades of blue, and look like so many butterflies flitting in the wind. It is often called a variety of V. cornuta, but why it is rather difficult to say, for it certainly bears no resemblance to that well-known species as far as the appearance of the flowers is concerned, and that is undoubtedly what one would go by in this case. After all, it is immaterial what its history may be; it is quite a gem for the garden. It can be readily raised from seed, and if sown now would produce good plants that would flower all next summer, or it may be sown in the spring, when it would commence to flower later.

Delphinium grandiflorum Cineraria.—The type of this beautiful plant is fairly well known, and is very attractive when grown in masses; but where possible the variety Cineraria should be procured, for its intense blue spikes are most conspicuous. It is unlike many Delphiniums on account of the flowers being upright, and entirely devoid of the spur which is characteristic of the majority. The spikes are produced from June to September, and they come tolerably true from seed, although, as most growers are aware, a slight variation will be evident from a large batch of seedlings. They grow from 18 inches to 24 inches high, and will thrive in any ordinary garden soil. We recently saw a fine batch in a nursery, and were impressed by the beautiful effect produced.

Pretty Floral Combinations.—Some uncommon, yet at the same time extremely pleasing, floral combinations are to be seen in Battersea Park, whose long-standing reputation for the excellence of its summer bedding is this season well upheld. Numerous striking effects may be noted, and of them the following appeal strongly to many: A bed of splendid examples of the rich-coloured Lobelia cardinalis Queen Victoria, alternated with standards of Veronica Andersonii variegata. Mixed throughout the bed are a few examples of the charming blue Salvia patens, the whole being edged with a bright blue Lobelia. An extremely mixed yet charming arrangement is a bed carpeted with a mauve-coloured Viola and edged with Fuchsia Golden Treasure, pegged down. Dotted over the Viola are standard plants of Veronica Andersonii variegata and fairly tall examples of Heliotrope, Gnaphalium microphyllum and Fuchsia Andenken an Henrich Henkel, this last being in better condition than one often meets with it. As a contrast to these mixtures is a bed solely of Pelargonium Gablee, both dwarf plants and tall standards being used.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Outdoor Figs.—To grow these satisfactorily outside, the roots must be restricted. They should be first potted into 12-inch pots and plunged below the rim of the pot, the hole in the bottom being previously made larger for the roots to get through. They are here plunged in a narrow border 3 feet wide and 18 inches deep and framed on a south-west wall, and the sun at this time of the year does not reach them till noon. They are now ripening a fine crop of good-sized fruit, the variety being Brown Turkey, planted three years ago. In such a dry summer as this they take an abundance of water. Neither is it necessary to cover them up in winter. Excellent fruit may be had from trees on an east wall fully exposed to the weather.—A. B. WADDS, *Englefield Gardens, Reading.*

A Good Bedding Rose.—I am greatly indebted to those readers who have so kindly given their experiences with Rose Irish Elegance in your last two issues. I am now sending you a photograph of what I consider to be the finest bedding or garden Rose of recent introduction, viz., Lady Alice Stanley. The photograph was taken about the middle of August, and therefore shows a bush bearing its second crop of flowers. Ever since the third week in June this bush has not been without blooms, and as these are large, of good shape, erect and fragrant, they are always admired. The colour is silvery pink, with the reverse of the petals glowing soft rose. The bush has an ideal, compact habit, and the large, tough, leathery leaves appear to be quite mildew-proof. Perhaps other readers will kindly relate their experiences with this Rose, and name what they consider to be the best bedding Rose introduced during the last six years.—A. B. ESSEX.

Humea elegans as a Bedding Plant.—This Australian biennial is now frequently used for bedding out during the summer months, and well-grown plants are, when properly grouped, very effective in the open garden. In this way, when fully exposed to light and air, the numerous feathery inflorescences acquire a much richer tone of colour than when they are kept in a greenhouse or conservatory. At Hampton Court, where this Humea is always well done, a large and very effective bed is planted with Cannas, above which tower a number of good examples of this Humea, sufficiently apart from each other to display the charms of each, yet near enough to form one harmonious whole. Seed of this Humea sown in the summer will furnish plants for the next year. They need careful watering, especially in the winter.—H. P.

Growing Spring-Flowering Bulbs in Fibre.—There are doubtless a large number of your readers who take great interest in this subject, and who, like myself, are not the possessors of a greenhouse and have to rely upon a sunny window to produce their flowers. The space there is naturally very limited, and will not permit very many bowls to be placed in the necessary sunlight. I recognise that growing bulbs in fibre gives excellent results for one year, but the bulbs are practically useless for the same purpose for a second time; therefore I know it will be no waste to spoil a bulb grown

them in the usual way, and in due time the Hyacinths come into bloom. As soon as they are past their best, I cut their stalks off level with the bulb, and level the fibre again to prevent them showing. By this time the Tulips, which are up to then slower in growth, are about an inch above the surface, but after the Hyacinths are cut away they develop much quicker, and in a few weeks come into bloom. I have grown a large number of flowers in this way, Tulips, Hyacinths, Narcissi, Daffodils, Crocuses, &c., but to my taste there is none to approach the exquisite beauty of a bowl

of these Murillo Tulips, with their huge white and pink double flowers, which continue in bloom for quite a long time. There are other combinations which will readily occur to your readers, such as early Narcissi, Daffodils, &c., used in connection with this beautiful Tulip, but I do not wish to get a better one than that here mentioned.—HARRY P. BOYCE, *Bristol.*

The Musk Plant.—While the present expressions of opinion are being given concerning the scent of the Musk plant, it may not be inappropriate to call attention to a wider use of this beautiful old garden subject—I mean as distinct from the usual method of growing it in pots. This year it is being used in some of the parks as a groundwork for Clarkias, and about eighteen months or so back I recorded in THE GARDEN our use of Musk as a carpeting for a batch of *Linum rubrum*, which combination gave a very pretty effect. Apart from these two examples, I have never seen nor heard of it being so utilised. Somehow or other the method of cultivating the Musk has always seemed to belong to the flower-pot for the greenhouse or the window-sill. But, I am bold to assert, it is well adapted for a larger service in the outside garden, and this whether it possesses fragrance or not. This year we have a length of Musk bordering a row of Sweet Peas, and some between a few plants of Damask Roses, and in both cases the effect has been pleasing. Musk does best in a moist or partially-shaded position, and where such conditions can be observed it would make a good bordering subject besides its use as a carpeting plant as alluded to above. It further makes a suitable plant for masking rough, damp corners of rockeries. A word about the scent of Musk. What we have growing in this gar-

ROSE LADY ALICE STANLEY IN A READER'S GARDEN. THE PHOTOGRAPH WAS TAKEN IN AUGUST.

den is not by any means so richly scented as was some we used to grow in a West of England garden a number of years ago. But what we have is faintly fragrant, as I have proved to-day (September 1) during a gentle rain-fall. Is it not possible that there has got abroad a spurious type of Musk? I have little doubt but what the genuine old sweet Musk is still to be found in country cottage gardens or in the windows, where it is always prized and tended so carefully.—CHARLES

TURNER, *Ken View Garden, Highgate.*

Matricaria eximea Silver Ball.—This attractive annual is a very fitting companion to *M. e. Golden Ball*. It possesses the floriferousness and compact habit of the latter, and is rather taller. With me it only attains a height of about nine inches. I have, however, seen it in another garden this summer, and it had there attained a height of some fifteen inches. This is all the more curious as the seed was supplied by the same firm (a leading one), and my neighbour's plants were not shaded in any way; nor were they, to all appearance, grown in richer soil than ours. As I intend to use this plant in a colour-scheme next season, I would be glad if some of your readers would say what height the plant attains with them. For the benefit of those who do not know this annual, I should say that its colour is a creamy white.—**CALEDONIA**

Rose Etoile de France.—In reply to Mr. C. Lemesle Adams, whose query appears on page 442 I have grown *Etoile de France* from the first, and largely, too. It has always come good here late in the season, and I invariably write and speak as I find. Looking over a number of Rose lists, I find none which complains of it in any way. It partakes of both parents—*Mme. Abel Chatenay* and *Fisher Holmes*—and although rather a bad opener in very wet or cold weather, we have many others much worse in that respect. Mine are upon the Briar stock, and in an ordinary light loam. I find it best when not overfed, and perhaps your correspondent might do better if he follows this hint. He is the first and only Rose-grower who has hinted to me that *Victor Hugo* was "not a thoroughly good doer." What say others?—**A. P., Uckfield.**

Colour Combinations.—Two flowers of very different orders and character are these I am now thinking of, yet they formed one of the daintiest and most charming combinations it is possible to imagine. In front of a large bed of dwarf *Lavender* were planted, fairly thickly, pink *Rhodanthes*, these latter, now flowering, not being quite so high as the *Lavender*. As one walks up to these beds from a distance, the effect is simple and exquisite. The soft daintiness of the rosy pink blends admirably with the hazy *Lavender*, and the whole seems carried beyond until lost in misty blue. Such is the poetry of colour; to another it may seem nothing more than a pinky blue. Yet another, this time decidedly more pronounced, the colours more vivid, less dainty, but not less charming, an excellent strain of *Nemesia strumosa*, with all the varied colours of this splendid annual. Planted in early June, being used as a groundwork, just a few seeds of *Nigella Miss Jekyll* were scattered broadcast after the planting. These have now opened a few flowers, just one here and there, and nothing could be more suitable as a setting to the blue, surrounded by the fennel-like green, than the golden variedness of the *Nemesia*. Last year I saw a beautiful blending of *Heliotrope* and *Musk*. The *Musk* was the groundwork, and was finely flowered. Above the yellow were shapely plants of the common *Heliotrope* dotted over the whole bed, with just sufficient low standard *Heliotropes* of the same variety to carry the whole into a billow of perfect harmony.—**H. R.**

The Best Bedding Roses.—I agree with Mr. Adams in your issue of September 6 regarding *Etoile de France*. I cannot think how "A. P." could recommend such a Rose. I grant at times it is superb, but generally it "blues" so badly as to quite ban it from our gardens, at least in any quantity. A far better variety would be *Château de Clos Vougeot*, although somewhat erratic in growth, a fault that could be remedied in a few

minutes by the aid of some unobtrusive sticks. What a glorious colour it is, and never a sign of burning, be it glaring hot for days. Another splendid dark Rose is *François Coppee*, a Hybrid Perpetual, but very free. I saw this very fine in the Public Rose Garden at Lyons last May, and *M. Pernet-Ducher* informs me it was one of the parents of *Château de Clos Vougeot*. Another fine dark Rose will be *Edward Mawley*; although somewhat inclined to "blue," yet it opens freely, and one can readily remove the oldest flowers. As regards scarlets, I should place Mrs. *Edward Powell* or *Leuchtfener* far in front of *George C. Waud*, which cannot be called scarlet, and, moreover, its growth is not always reliable. I have no fault to find with the yellows, excepting that "A. P." has omitted four of the best, viz., *Lady Hillingdon*, *Jeanne Philippe*, *Melody* and *Paula*. Then, again, who will want Mrs. *Sharman Crawford* with its mildew tendency, when they can have such glorious Roses as *Lady Alice Stanley*, *Margaret* and *Countess of Shaftesbury*? Why *Mme. Abel Chatenay* was omitted I cannot conceive. By judicious pruning and partially pegging down one or two shoots it cannot be surpassed as a pink bedder, and *Mme. Second Weber* is far ahead of *Killarney*.—**DANECROFT.**

Influence of Artificial Manures on Vegetables. Speaking about our *Celery* the other day, my employer remarked that a friend who had called a few days previously had told him that he grew all his *Celery* without the help of animal manure, but relied entirely on artificials, such as superphosphate, &c., because he found the quality of the *Celery* was much superior when the animal manure was omitted and only artificials used. This statement quite upset all our previous ideas on this matter, it having always been our opinion that instead of improving the quality of vegetables, the use of artificials always had a detrimental influence on their quality. We are quite aware that such manures very considerably increase the size and bulk of many crops, but that is an altogether different matter from the quality. Further, it has been our experience that the use of artificials has an adverse influence on the keeping properties of many vegetables, especially Onions, which will rarely keep till February if they have been subjected to liberal doses of artificial manures during their period of growth. In agriculture, too, we are all familiar with the baneful influence on the quality of hay which has been treated with nitrate of soda. Potatoes also often suffer from the same cause, and we are afraid many garden vegetables are also injuriously affected by a too generous application of chemical manures. One great danger lies in the ease with which it can be applied, as a few handfuls of concentrated manure can so easily be scattered, whereas a similar number of barrow-loads of animal manure requires more muscle to get it incorporated with the soil. However, we would be glad to know the views of some of your experienced correspondents on this important point.—**W. L.**

FORTHCOMING EVENTS.

- September 22.—National Chrysanthemum Society's Executive and Floral Committees Meeting.
- September 23.—Royal Horticultural Society's Meeting and Vegetable Show.
- September 24.—North of England Horticultural Society's Show at Kendal (two days).
- September 25.—Royal Horticultural Society's Show of British-grown Fruit (two days).
- September 26.—Annual Conference of Affiliated Mutual Improvement Societies at the Royal Horticultural Society's Hall, Westminster.

THE ROSE GARDEN.

THE BEST WHITE ROSE FOR BEDDING.
